108680 Polariton solitary waves in a quasi-one-dimensional ferromagnet. R.Boudreau, A.Caille (Dept. de Phys., Univ. de Sherbrooke, Sherbrooke, Quebec, Canada).
Solid State Commun. (USA), vol.47, no.10, p.783-7 (Sept. 1983). In French.
Spin dynamics in an easy plane magnetic chain has been studied in terms of polaritons and solitons, when the coupling between magnons and their induced dipolar electromagnetic field is included. For a moderate external magnetic field in the easy plane, non-topoligical, classical ϕ^4 solitons can describe the dynamics of spins dressed with the electromagnetic field. The solitary wave thus produced propagates at phase velocities bounded by the two limiting phase velocities of the polariton dispersion relations. (15 refs.)

75.30G Anisotropy

108681 Determination of the magnetic anisotropy of ferrofluids from torque magnetometry data. R.W.Chantrell (Dept. of Phys. & Astron., Preston Polytech., Preston, England), B.K.Tanner, S.R.Hoon.
J. Magn. & Magn. Mater. (Netherlands), vol.38, no.1, p.83-92 (Aug. 1983).
A theoretical analysis is presented which enables the uniaxial magnetic anisotropy constant K_1 of particles in ferrofluids, frozen in an external field, to be obtained from torque magnetometry measurements. The two-fold symmetry of the torque curve, found experimentally, is correctly predicted. An asymptotic solution is found which enables K_1 to be determined without recourse to iterative numerical methods. In this limit, the torque amplitude varies linearly with the inverse of the freezing field for large freezing fields. For all cases, exraction of K_1 requires an accurate knowledge of the particle size distribution parameters. (9 refs.)

108682 The role of two-level systems in amorphous metallic alloys. I. Induced anisotropy in amorphous ferromagnets. H.Kronmuller (Max-Planck-Inst. fur Metallforschung, Inst. fur Phys., Stuttgart, Germany).
Phys. Status Solidi b (Germany), vol.118, no.2, p.661-73 (1 Aug. 1983).
The induced anisotropy in amorphous ferromagnets is attributed to the directional ordering of atom pair axes. The thermodynamics and micromagnetic background of this process is treated on the basis of two-level systems which are identified with mobile atom pairs in the neighbourhood of free volumes. The role of 'reversible' and of 'irreversible' relaxation processes is discussed in detail. (26 refs.)

108683 Curie temperature in homologous series of Heusler alloys. L.S.Palatnik, I.I.Fal'ko.
Dopov. Akad. Nauk UkRSR. Ser. A (USSR), no.8, p.51-3 (1983). In Ukrainian.
The δ-Mn BCC lattice constant and the critical Curie temperature of transition from ferro-to paramagnetic state are estimated by a crystallochemical analysis of the Heusler alloy structure for predicted but not yet studied 'homologous' series of alloys: Co_2MnC, Co_2MnPb; Ni_2MnB, Ni_2MnAl, Ni_2MnTl, Cu_2MnB, Cu_2MnGa, Cu_2MnTl. (12 refs.)

108684 The anomalous orientation transition in disordered weak ferromagnets. E.V.Sinitsyn, I.G.Bostrem.
Fiz. Nizk. Temp. (USSR), vol.9, no.8, p.873-6 (Aug. 1983). In Russian. English translation in: *Sov. J. Low Temp. Phys. (USA)*
The possibility is shown for the orientation transition induced by the external field applied along the weak magnetic moment to occur in noncollinear antiferromagnets with fluctuations of Dzyaloshinsky's interaction. The magnetization curve for the systems undergoing the transition is similar to that for the two-sublattice ferrimagnet. (6 refs.)

108685 Thermodynamics and the spin-glass transition. C.N.Guy, J.G.Park (Blackett Lab., Imperial Coll., London, England).
J. Phys. F (GB), vol.13, no.9, p.1955-64 (Sept. 1983).
New measurements of the magnetisation of a CuMn spin glass (0.25 at.%) are presented in order to test the hypothesis that the field-cooled magnetisation $M(H,T)$ of a spin glass can be treated by the relationships of equilibrium thermodynamics. Comparisons are made between direct measurements of $(\partial M/\partial T)_H$ and $(\partial^2 M/\partial T^2)_H$ and those deduced from recent heat capacity and magnetocaloric experiments performed on similar specimens. The results show that above 0.05 T all three experiments agree closely. At low fields, however, there are small but significant differences that most probably arise from the use of different specimens for the three experiments but might have different causes. It is concluded that the equilibrium hypothesis is consistent with the experimental data at present available but that further experiments at low fields are required to test it thoroughly. The hypothesis has the remarkable implication that just below the glass temperature the entropy of a field-cooled spin glass increases with field in low fields and goes through a maximum as the field is increased (at 0.05 T for our specimen). An analogy is drawn between this behaviour and that of an ordered antiferromagnet for which the entropy is also an increasing function of field. (12 refs.)

108686 Magnetic properties of dysprosium oxisulphate ($Dy_2O_2SO_4$). H.Hulsing, A.Kasten (Phys. Inst., Univ. Karlsruhe, Karlsruhe, Germany).
Phys. Status Solidi b (Germany), vol.118, no.2, p.725-41 (1 Aug. 1983).
Below $T_N=(8.05\pm0.10)$K $Dy_2O_2SO_4$ is a nearly two-dimensional co-linear Ising antiferromagnet. At low temperatures ($T\leq2.4$K) and in external magnetic fields between 1.7 and 2.2 T along the ordering direction there is an intermediate ferrimagnetic phase with a $T=0$ magnetization of 1/3 of the saturation value. From Zeeman spectroscopy and theoretical considerations the structure of the magnetic phases are derived. The details of the phase diagram as established by magnetization measurements are not reproduced by mean field calculations. At the boundary between the antiferromagnetic and ferrimagnetic phase there is a hysteresis which is asymmetric with respect to the sweep direction of the external magnetic field. This behaviour can be explained by the occurrence of different magnetization processes. The time constants as determined experimentally are of the order of ten minutes. (19 refs.)

108687 Magnetic properties and thermal expansion of $(Zr_{1-x}Ta_x)Fe_2$. Y.Muraoka, M.Shiga, Y.Nakamura (Dept. of Metal Sci. & Technol., Kyoto Univ., Kyoto, Japan).
Phys. Status Solidi a (Germany), vol.78, no.2, p.717-22 (16 Aug. 1983).
Magnetization, Mossbauer effect, and thermal expansion are measured on the pseudobinary $(Zr_{1-x}Ta_x)Fe_2$ Laves phase intermetallic compounds. With increasing x, the crystal structure changes from C15 to C14 around $x=0.3$ to 0.4. Ferromagnetism is observed for the C15 phase and antiferromagnetism for the C14 phase, where the spin structure is considered to be the same as that of $TiFe_2$. An Invar-like large thermal expansion anomaly is observed, most prominently for $x=0.2$. A strong magnetovolume coupling is found in the antiferromagnetic C14 phase as well as in the ferromagnetic C15 phase. (22 refs.)

108688 Successive phase transitions in a random system $\mathrm{Mn_{1-x}Zn_x(HCOO)_2.2D_2O}$. M.Matsuura, K.Koyama, Y.Murakami, Y.Ajiro, N.Terata (Faculty of Engng. Sci., Osaka Univ., Toyonaka, Japan).
Physica B & C (Netherlands), vol.120B+C, no.1-3, p.206 (May 1983). (Yamada Conference VI on Neutron Scattering in Condensed Matter, Hakone, Japan, 1-4 Sept. 1982).
$\mathrm{Mn(HCOO)_2.2D_2O}$(MnF2D) is a quasi two-dimensional(2D) Heisenberg antiferromagnet. The canting interaction in the system couples the staggered mode weakly to the uniform one. Thus, susceptibility X_0 and magnetization M are sensitive indicators of the staggered parameters X_{os} and L, respectively. A sharp peak of X_0 of MnF2D at T_{N}, which shows the divergence of X_{os}, is split into three by random mixing of ZnF2D. Correspondingly, spontaneous magnetization M_{s}, which appears by cooling the sample in a field into the ordered phase and then removing the field, decreases in three stages as the temperature increases. The first singular point is the transition temperature T_{N} from the paramagnetic into an ordered phase. The phase below the final point T_{p2} is found by NMR to be an ordered state with the same spin configuration as in the pure system below T_{N}. (no refs.)

108689 Investigation of the magnetic and superconducting properties of $\mathrm{(Er_{1-x}Ho_x)Rh_4B_4}$. J.W.Lynn (Dept. of Phys., Univ. of Maryland, College Park, MD, USA), R.N.Shelton, H.E.Horng, C.J.Glinka.
Physica B & C (Netherlands), vol.120B+C, no.1-3, p.224-6 (May 1983). (Yamada Conference VI on Neutron Scattering in Condensed Matter, Hakone, Japan, 1-4 Sept. 1982).
Neutron scattering, susceptibility and resistivity measurements have been carried out for the system $\mathrm{(Er_{1-x}Ho_x)Rh_4B_4}$ near the multicritical point where the magnetic and superconducting phase boundaries converge ($x \simeq 0.9$). On the Ho rich side ($x > x_{\mathrm{c}}$) no superconducting state is observed, whereas for $x < x_{\mathrm{c}}$ there is a temperature interval $T_{\mathrm{c2}} < T < T_{\mathrm{cl}}$ where superconductivity exists. For all concentrations studied a transition to a long-range ordered ferromagnet is observed, with the Ho moments ordering along the tetragonal axis. The behavior of the order parameter is mean-field like, indicating that the range of the magnetic interactions is large. For $x \sim x_{\mathrm{c}}$ the ferromagnetic transition appears to be continuous, and occurs within the superconducting phase, suggesting the coexistence of ferromagnetic order and superconductivity. Below T_{m}, strongly temperature dependent small angle scattering is observed, characterized by a cross section of the Porod form $S(Q)=A(T)/Q^4$. The strength of the scattering $A(T)$ increases monotonically with decreasing temperature. (8 refs.)

108690 Magnetic phase transition in $\mathrm{(Mn_{0.95}Ni_{0.05})_3B_4}$. T.Ishii, M.Shimada, M.Koizumi (Inst. of Sci. and Industrial Res., Osaka Univ., Osaka, Japan), Y.Nishihara, Y.Yamaguchi.
Solid State Commun. (USA), vol.47, no.4, p.303-5 (July 1983).
It was found that the metallic compound $\mathrm{(Mn_{0.95}Ni_{0.05})_3B_4}$ was ferromagnetic below 195K and antiferromagnetic between 195 and 354K. The transition temperature from ferromagnetic to antiferromagnetic increases with increasing external magnetic field. On the other hand, the transition temperature from antiferromagnetic to paramagnetic decreases with increasing magnetic field. It is expected that the present results might be explained by the theoretical results on the coexistence of ferro- and antiferromagnetism in the itinerant electron system reported by Moriya and Usami (1977). (6 refs.)

108691 Local and itinerant magnetism and superconductivity in R $\mathrm{Rh_2Si_2}$ (R=rare earth). I.Felner, I.Nowik (Racah Inst. of Phys., Hebrew Univ., Jerusalem, Israel).
Solid State Commun. (USA), vol.47, no.10, p.831-4 (Sept. 1983).
Magnetization and Mossbauer studies reveal that R $\mathrm{Rh_2Si_2}$ (R=rare earth) have two magnetic phase transitions, one corresponding to the ordering of the rare earth (T_{N}=27-130K) and the other to the itinerant electron ordering of the Rh sublattice (T_{M}=5-17K). $\mathrm{LaRh_2Si_2}$ has also been studied by resistivity, specific heat and a.c. susceptibility measurements. All studies indicate that $\mathrm{LaRh_2Si_2}$ orders magnetically at $T_{\mathrm{M}}\mathrm{K}=7\mathrm{K}$ and becomes superconducting, type II, at $T_{\mathrm{c}}=3.8\pm0.2\mathrm{K}$. (8 refs.)

108692 Some refrigerant materials for a magnetic refrigerator near room temperature. H.Maeda, M.Sato, M.Uehara (Tsukuba Labs., Nat. Res. Inst. for Metals, Ibaraki, Japan).
J. Jpn. Inst. Met. (Japan), vol.47, no.8, p.683-7 (Aug. 1983). In Japanese.
For $\mathrm{Ni_2(Mn_{1-x}M_x)Sn}$ with M=V and Nb (x=0.1, 0.2, 0.3 and 0.4), and $\mathrm{Mn_{3-y-z}Cr_yAlC_{1+z}}$ (y=0 and z=−0.16, −0.8 and 0, and z=0.1 and y=0, 0.06, 0.15 and 0.26) the Curie temperature T_{c}, the saturation magnetization M_{s}, and the magnetic entropy ΔS_{M} near T_{c} have been studied. The values of ΔS_{M} are determined from the measured magnetization-temperature curves. As x or $(y+z)$ increases, the values of T_{c} linearly decrease from room temperature to about 200K, and M_{s} also linearly decreases. The largest values of the maximum magnetic entropy $(\Delta S_{\mathrm{M}})_{\mathrm{Max}}$ obtained at x=0.1 to 0.2 in the former system and at y=0 and z=0.1 in the latter one reach about half of that of Gd, and $(\Delta S_{\mathrm{M}})_{\mathrm{Max}}$ gradually decreases with increasing x or y. Furthermore, the values of ΔS_{M} are calculated using a molecular field approximation. The calculated values are in agreement with the experimental ones for the materials with low x or y, but the difference between both values becomes large with increasing x or y, and particularly in the former system with M=Nb and in the latter one with $z \leq 0$. (10 refs.)

108693 Fe-Zr amorphous alloys for magnetic refrigerants near room temperature. H.Maeda, M.Sato, M.Uehara (Tsukuba Labs., Nat. Res. Inst. for Metals, Ibaraki, Japan).
J. Jpn. Inst. Met. (Japan), vol.47, no.8, p.688-91 (Aug. 1983). In Japanese.
$\mathrm{(Fe_{1-x}Ni_x)_{90}Zr_{10}}$ (x=0, 0.1, 0.02 and 0.03) and $\mathrm{(Fe_{0.95}M_{0.05})_{90}Zr_{10}}$ (M=Al, Si, Ga, Ge, and Sn) amorphous alloys with thickness of about 20 μm were prepared by a single roll-quenching technique and a piston anvil-quenching one. The Curie temperature T_{c}, the saturation magnetization M_{s} and the magnetic entropy ΔS_{M} of the alloys have been investigated. The values of T_{c} increase from 240K to near room temperature with increasing x up to 0.05, tending to increase with increasing atomic number of the elements M. The values of ΔS_{M} as well as M_{s} increase with increasing x, and ΔS_{M} increases in proportion to the magnetic field H. The maximum magnetic entropy $(\Delta S_{\mathrm{M}})_{\mathrm{Max}}$ of 13 $\mathrm{kJ.m^{-3}.K^{-1}}$ near T_{c} at H up to 1.12 $\mathrm{MA.m^{-1}}$ is about 50% smaller than that of Gd. However, the change in ΔS_{M} with temperature T is much smaller than those of Gd and other crystallines. The curves of ΔS_{M}-T cannot be approximated by a molecular field theory. (6 refs.)

75.40 CRITICAL-POINT EFFECTS, SPECIFIC HEATS, SHORT-RANGE ORDER

(inc. spin glasses)

108694 Dynamics of the soliton instability in the easy-plane ferromagnetic chain. H.J.Mikeska, K.Osano (Inst. fur Theoretische Phys., Univ. Hannover, Hannover, Germany).
Z. Phys. B (Germany), vol.52, no.2, p.111-16 (1983).
The authors present results on the nonlinear dynamics of a realistic classical easy-plane ferromagnetic chain in an external magnetic field, concerning in particular the dependence of soliton solutions on the strength of the single-ion anisotropy. After giving two exact static solutions, slowly moving permanent profile solutions are investigated. The velocity dependent contribution tothe energy as well as the amplitude of the out-of-plane distortion of these solutions is shown to diverge when the Magyari-Thomas-Kumar instability of the static Sine-Gordon soliton is approached. The dynamic origin of this instability is shown to be an unstable behaviour of the soliton towards spontaneous motion instead of a soft mode. (11 refs.)

108695 Investigation of directional short-range ordering in iron alloys by the NGR method. G.A.Dorofeyev, V.S.Litvinov (Ural Polytechnical Inst., Sverdlovsk, USSR).
Phys. Met. (GB). Translation of: Metallofizika, Kiev (USSR), vol.4, no.3, p.470-82 (1982). [received: Aug. 1983]
Discusses new possibilities of applying the nuclear gamma resonance (NGR) method to investigate directional ordering of BCC and FCC ferromagnetic alloys. Directional ordering in the arrangement of the Fe and Si atoms was found in iron silicide (5.7 at.% Si) slowly cooled from 950°C. It is shown that Mossbauer spectra of iron silicide can best be described by assuming the disperse directional short-range ordering of atomic structure of the $\mathrm{Fe_{15}Si}$ type. In the first coordination sphere this structure is characterized by short-range order, and in the second by preferred orientation of the Fe-Fe atomic pairs along the direction of spontaneous magnetization. (18 refs.)

108696 Coexistence of the long-range magnetic order and spin-glass state in ordering alloy $FePd_2Au$ with the FCC lattice. M.A.Borozdina, Yu.A.Vereshchagin, F.A.Sidorenko, A.A.Kuranov, P.V.Gel'd, Yu.G.Karpov (S.M. Kirov Ural Polytech. Inst., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.80-4 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
Magnetic properties of the alloy $FePd_2Au$ formed as a result of atomic ordering were determined. It was found that the competition between interactions with different signs in $FePd_2Au$ resulted in a transition from ferromagnetism in the atomically disordered state to antiferromagnetism in the ordered state, and the process involved the appearance and coexistence of ferromagnetic, antiferromagnetic, and spin-glass states. (12 refs.) *A.T.*

108697 On stable three-dimensional low-amplitude solitons in magnetic materials. B.A.Ivanov, A.M.Kosevich.
Fiz. Nizk. Temp. (USSR), vol.9, no.8, p.845-50 (Aug. 1983). In Russian. English translation in: *Sov. J. Low Temp. Phys. (USA)*
The authors are considering three-dimensional centrally symmetric solitons of an equation similar to the Schrodinger nonlinear equation, but unlike the standard situation containing fourth (not second) derivatives with respect to coordinates. It describes macroscopically quasi-particles whose effective mass goes to infinity. It is shown that in contrast to the standard situation, in such systems there may be three-dimensional low-amplitude solitons representing bound states of a large number of quasi-particles. The energy per quasi-particle in the bound state is smaller than that of a continuous spectrum which suggests stability of the soliton. (8 refs.)

108698 Critical measurements in the spin glass CuMn. R.Omari, J.J.Prejean, J.Souletie (Centre de Recherches sur les Tres Basses Temperatures, CNRS, Grenoble, France).
J. Phys. (France), vol.44, no.9, p.1069-83 (Sept. 1983).
The authors present experimental data on the magnetization $M(H)$ of a CuMn 1 at.% in the range $T_c \leq T \leq 4\ T_c$, $0<H<7$ teslas. They took special precautions in order to eliminate systematic errors and improve the reliability of the data. It was then possible to study the temperature dependence of the first coefficients A_1, A_3, A_5 in the expansion of the low field magnetization data in terms of odd powers of H/T ($M=\Sigma A_{2n+1}(^H/_T)^{2n+1}$), in the range $1.1\ T_c \leq T \leq 4\ T_c$. From the divergence of A_3 and A_5 (which vary over 3 and 6 orders of magnitude respectively in this range), they derive two exponents ($\gamma=3.25$, $\beta=0.75\pm0.25$) which allow the rescaling of all the data points onto a universal function. The success of the scaling argument is strong evidence in favour of the existence of a phase transition in three dimensions for RKKY spin glasses. (29 refs.)

108699 Order parameters in spin glasses. K.H.Fischer (Inst. fur Festkorperforschung, KFA Julich, Julich, Germany), J.A.Hertz.
J. Phys. C (GB), vol.16, no.25, p.5017-22 (10 Sept. 1983).
Various proposed characterisations of the freezing in spin glasses are examined in the light of the fluctuation-dissipation theorem. The authors find a variety of possible choices for the order parameter, all conseistent with linear respons theory, differing from each other according to the set of states accessible in the different situations. (35 refs.)

108700 On the internal fields in vector spin glasses with random uniaxial local anisotropy. O.Hudak (Inst. of Experimental Phys., Slovak Acad. of Sci., Kosice, Czechoslovakia).
J. Phys. C (GB), vol.16, no.26, p.5203-9 (20 Sept. 1983).
Local internal fields h_i^0 in vector spin glasses with random uniaxial local anisotropy are shown to be positive on all non-isolated spins whenever the spin state corresponds to any minimum of configurational energy within the classical theory. Moreover it is shown that there exists a lower positive bound on the values of the local internal fields. This bound depends on the exchange interaction constants and on the strength of the local anisotropy. (9 refs.)

108701 A study of the critical factorization of ternary dynamical spin correlations by the scattering of polarized neutrons in Fe above T_c. A.I.Okorokov, A.G.Gukasov, V.N.Slyusar, B.P.Toperverg, O.Scharpf, F.Fujara (B.P. Konstantinov Leningrad Inst. of Nuclear Phys., Acad. of Sci., Gatchina, USSR).
JETP Lett. (USA), vol.37, no.6, p.319-22 (20 March 1983). Translation of: *Pis'ma v Zh. Eksp. & Teor. Fiz. (USSR)*, vol.37, no.6, p.269-72 (20 March 1983). [received: Sept. 1983]
It is shown experimentally that in the critical region $qR_c>1$ the temperature dependence of the ternary dynamical spin correlator agrees with the predictions of the Polyakov-Kadanoff operator algebra generalized to dynamical correlations. (7 refs.)

108702 A static interpretation of the order-parameters in spin-glasses. H.Orland (Inst. for Theoretical Phys., Univ. of California, Santa Barbara, CA, USA).
J. Phys. Lett. (France), vol.44, no.16, p.L673-7 (15 Aug. 1983).
The spin-glass phase is described as a statistical mixture of an infinite number of phases. The order-parameters $q(x)$ and $\Delta(x)$, with $x \in [0,1]$ measure the correlation between the phases, and the linear response anomaly respectively. Sompolinsky's solution (1981) is recovered and reinterpreted. (14 refs.)

108703 Spin glass with short-range interaction induced by an electromagnetic field in semiconductors. II. High temperatures domain. M.Crisan, Zs.Gulacsi, M.Gulacsi (Dept. of Phys., Cluj Univ., Cluj, Rumania).
J. Magn. & Magn. Mater. (Netherlands), vol.38, no.1, p.67-77 (Aug. 1983).
For pt.I see ibid., vol.36, p.47 (1983). The spin-glass state which occurs in semiconductors due to the spin-spin interaction induced by an electromagnetic field is analysed in the high-temperature domain. The Abrikosov-Moukin model (1980) has been considered for this analysis, and the specific heat and magnetic susceptibility as function of temperature have been obtained. (4 refs.)

108704 Critical behavior of $Fe_{15}Ni_{65}B_{18}Si_2$ ferromagnetic glass. Z.Marohnic, D.Drobac, E.Babic, K.Zadro (Inst. of Phys., Univ. of Zagreb, Zagreb, Yugoslavia).
J. Magn. & Magn. Mater. (Netherlands), vol.38, no.1, p.93-8 (Aug. 1983).
AC susceptibility, magnetization and electrical resistivity around the Curie temperature (T_c) were measured for $Fe_{15}Ni_{65}B_{18}Si_2$ glass. The results yield $T_c=(307.6\pm0.1)$K and the following critical exponents $\gamma=1.50\pm0.03$, $\beta=0.375\pm0.01$, $\delta=5.1\pm0.1$ and $\alpha=-0.29\pm0.05$. These values were obtained in the reduced temperature interval $1\times10^{-3} \leq |T-T_c|/T_c \leq 5\times10^{-2}$. In spite of the fact that these values for the critical exponents were obtained from different measurements they obey the equality relations $\gamma=\beta(\delta-1)$ and $\gamma+2\beta+\alpha=2$. Reduced magnetisation and field follow a magnetic equation of state derived for a second-order phase transition over a wide temperature range. This set of critical exponents is compared with those derived from the Heisenberg model as well as with the usual ones for a pure crystalline ferromagnets. The comparison shows that the values of $|\alpha|$ and γ, for the present alloy, are considerably larger than those from the model and the usual crystalline ones. A similar difference is also observed in some other amorphous and dilute crystalline ferromagnets and is probably due to magnetic inhomogeneities. (30 refs.)

108705 Dynamics of the relaxation-time spectrum in a CuMn spin-glass. L.Lundgren, P.Svedlindh, P.Nordblad, O.Beckman (Dept. of Solid State Phys., Inst. of Technol., Univ. of Uppsala, Uppsala, Sweden).
Phys. Rev. Lett. (USA), vol.51, no.10, p.911-14 (5 Sept. 1983).
SQUID magnetometry measurements on a *Cu*Mn spin-glass reveal that the zero-field-cooled magnetization strongly depends on the time the sample is kept at constant temperature prior to the field application. This result is evidently at variance with the common belief that an equilibrium spin-glass state is quickly obtained after cooling in zero field. The nonequilibrium behavior, as reflected in the complex time dependence of $\partial m/\partial \ln t$, is interpreted to arise from slow dynamics of the relaxation-time spectrum. (8 refs.)

108706 Evidence for power-law spin-correlation decay from muon spin relaxation in *Ag*Mn spin-glass. D.E.MacLaughlin, L.C.Gupta (Univ. of California, Riverside, CA, USA), D.W.Cooke, R.H.Heffner, M.Leon, M.E.Schillaci.
Phys. Rev. Lett. (USA), vol.51, no.10, p.927-30 (5 Sept. 1983).
Muon spin relaxation measurements have been carried out below the 'glass' temperature T_g in *Ag*Mn spin-glasses. The muon spin-lattice relaxation rate varies with field H as $H^{-0.46\pm0.05}$ for $0.30 \leq T/T_g \leq 0.66$. This suggests that impurity-spin correlations decay with time as $t^{-\nu}$, $\nu \simeq 0.54\pm0.05$, in contrast to the more usual exponential decay. The present data therefore agree quantitatively with the prediction $\nu \simeq {}^1/_2$ of mean-field dynamic theories. (18 refs.)

108707 Magnetic short-range order and spin waves in Fe_3Si above the Curie temperature. P.V.Blanckenhagen, C.Lin (Inst. fur Angewandte Kernphys., Kernforschungszentrum Karlsruhe, Karlsruhe, Germany).
Physica B & C (Netherlands), vol.120B+C, no.1-3, p.173-5 (May 1983). (Yamada Conference VI on Neutron Scattering in Condensed Matter, Hakone, Japan, 1-4 Sept. 1982).
In neutron scattering experiments on Fe_3Si the existence of magnetic short-range order and of spin-waves was detected at temperatures up to 250K above the Curie temperatures. (11 refs.)

108708 Theory of excitations in the 1d singlet ground state magnet $CsFeCl_3$. P.-A.Lindgard (Riso Nat. Lab., Roskilde, Denmark).
Physica B & C (Netherlands), vol.120B+C, no.1-3, p.190-2 (May 1983). (Yamada Conference VI on Neutron Scattering in Condensed Matter, Hakone, Japan, 1-4 Sept. 1982).
$CsFeCl_3$ is a quasi one-dimensional planar magnet. Compared with the similar $CsNiF_3$ there is, however, a significant coupling between the chains which leads to an interesting soft mode behaviour. Using the correlation theory the temperature dependence and damping of the excitons are calculated and it is predicted that a central peak should appear at the soft mode wave vector. This mode absorbs all the spectral weight at the transition to long range order, whereas the soft mode tends to a finite frequency with decreasing weight. (6 refs.)

108709 Scaling of T_1^{-1} with T/T_{sf} in nearly magnetic systems. M.T.Beal-Monod (Lab. de Phys. des Solides, Univ. Paris-Sud, Orsay, France).
Phys. Rev. B (USA), vol.28, no.3, p.1630-2 (1 Aug. 1983).
The author points out that the calculation of the longitudinal spin-relaxation rate $T_1{-}^1$ in a strongly interacting, nearly magnetic Fermi system is a function of only the reduced temperature T/T_{sf} (where T_{sf} is the spin-fluctuation temperature, i.e. the Fermi temperature renormalized by the interactions), in the whole degenerate regime, $T<T_F$ (T_F, the degeneracy Fermi temperature), below, as well as above, T_{sf}. (10 refs.)

108710 Soliton confinement in polyacetylene due to interchain coupling. D.Baeriswyl, K.Maki (Dept. of Phys., Univ. of Southern California, Los Angeles, CA, USA).
Phys. Rev. B (USA), vol.28, no.4, p.2068-73 (15 Aug. 1983).
The energy involved in the relative ordering of the dimerization patterns of neighboring $(CH)_x$ chains is evaluated with a model where the coupling is due to the interchain hopping of the π electrons. It is shown that this mechanism favors antiferromagnetic order between neighboring chains. Furthermore, it leads to soliton confinement. The energy associated with a pair of solitons on the same chain separated by l/a (CH) units is given by $E_c \simeq Wl/a$, where $W=4t_\perp{}^2/\pi t_0$. Substituting accepted values for the interchain and intrachain hopping energies, $t_\perp$ and t_0, the authors find $W \sim 10-3$K. (22 refs.)

108711 A new mean field theory on critical scaling in spin-glasses. K.Honda (Dept. of Appl. Phys., Nagoya Univ., Nagoya, Japan).
Solid State Commun. (USA), vol.47, no.10, p.815-18 (Sept. 1983).
The critical exponent γ, δ in the non-linear susceptibility are given by making use of the free energy simply consisting of order parameter, magnetization and what was previously named an internal field parameter. The crossover exponent ϕ also is obtained. It is found that they satisfy the scaling relations proposed independently by Suzuki et al. (1977). (21 refs.)

108712 Spin glassiness and ferromagnetism in disordered Ni-Mn alloys. J.S.Kouvel (Dept. of Phys., Univ. of Illinois, Chicago, IL, USA).
Alloy Phase Diagrams. Proceedings of a Symposium, Boston, MA, USA, Nov. 1982 (New York, USA: North-Holland 1983), p.353-9
From magnetic measurements, the alloy $Ni_{78}Mn_{22}$ is found to undergo a field-induced transition from spin glassiness to ferromagnetism at a critical field that decreases from ~140 Oe to zero as the temperature is raised from 4.2K to40K, the ferromagnetic Curie point being ~270K. The alloy $Ni_{74}Mn_{26}$ is found to transform at 80K from a spin glass to a state of infinite initial susceptibility but no spontaneous magnetization and to remain so up to 155K, where it becomes paramagnetic. The spin-glass properties of $Ni_{78}Mn_{22}$ below 40K and of $Ni_{74}Mn_{26}$ below 80K include displayed hysteresis loops produced by cooling in a field. The changes in the hysteresis loops upon subsequent warming correspond to a gradual conversion of a unidirectional anisotropy to a uniaxial anisotropy. (16 refs.)

75.40D Ising and other classical spin models

108713 Phase diagrams for the spin-1 model with two- and three-spin interactions in the mean field approximation. M.Napiorkowski (Inst. of Theoretical Phys., Warsaw Univ., Warsaw, Poland).
Acta Phys. Pol. A (Poland), vol.A64, no.2, p.185-95 (Aug. 1983).
The spin-1 triangular model with two- and three-spin interactions in the presence of magnetic field is analyzed using the mean field approximation. The phase diagrams for different values of two- and three-spin couplings are presented. A comparison with analogous Ising-spin system is given. (10 refs.)

108714 A real-space renormalization group method for continuous-variable Ising model. II. W.Jezewski (Inst. of Molecular Phys., Polish Acad. of Sci., Poznan, Poland).
Acta Phys. Pol. A (Poland), vol.A64, no.2, p.215-23 (Aug. 1983).
For pt. I see ibid., vol.A53, p.163 (1980). A real-space renormalization group method is used to analyze the critical behaviour of the square Ising model described by an effective continuous-variable Hamiltonian on a lattice. The method is based on the renormalization transformation which consists of the decimation transformation in the integral form and the rescaling of variables. The thermal and magnetic critical exponents, ν and η, as well as the inverse critical temperature $\mathcal{K}_c$ are calculated using the cumulant expansion to second order. The values of ν and $\mathcal{K}_c$ are found to be in good agreement with the exact Onsager's results. (19 refs.)

108715 A continued fraction expansion of thermodynamic quantities using high-temperature expansions. B.Michalik (Inst. of Phys., Czechosl. Acad. Sci., Praha, Czechoslovakia).
Czech. J. Phys. Sect. B (Czechoslovakia), vol.B33, no.8, p.941-50 (1983).
An algorithm for expanding a function into a continued fraction is given and applied to the dimensionless free energy and susceptibility of the Ising model of ferromagnetism. In terms of this expansion, approximate positions of critical points could be calculated. The author did it for the following lattices: p.t., s.q., s.c., f.c.c., b.c.c. and d. An inverse problem is solved, namely, the construction of the high-temperature expansion from a known development into the continued fraction. The author has found that some coefficients of the high-temperature expansion of the susceptibility are interrelated. Examples of these relations and a list of all mutually dependent coefficients are given for the above-mentioned lattices. (7 refs.)

108716 The order parameter in a spin glass. A.C.D.Van Enter, R.B.Griffiths (IHES, Bures-sur-Yvette, France).
Commun. Math. Phys. (Germany), vol.90, no.3, p.319-27 (1983).
Various possible precise definitions of an Edwards-Anderson type of order parameter for an Ising model spin glass are considered, using boundary conditions for a finite system, states of an infinite system and a duplicate-system approach. Several of these definitions are shown to yield identical results. (20 refs.)

108717 Monte Carlo study of a triangular Ising lattice. II. Occurrence of the Kosterlitz-Thouless-like phase transition. H.Takayama, K.Matsumoto, H.Kawahara (Dept. of Phys., Hokkaido Univ., Sapporo, Japan), K.Wada.
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2888-97 (Aug. 1983).
For pt.I see ibid., vol.52, p.1774 (1983). A two-dimensional triangular Ising lattice with the nearest-neighbor antiferromagnetic interaction J_1 and the next-nearest-neighbor ferromagnetic interaction $-J_2$ is studied by the Monte Carlo simulation. It is shown that the system with a finite J_2 undergoes the successive phase transitions, paramagnetic$\rightarrow$Kosterlitz-Thouless (KT)-like$\rightarrow$ferrimagnetic phases, as temperature decreases. The sublattice switching phenomenon observed in previous work is shown to be an intrinsic property inherent to the present system which has an XY character. The marginal exponent of the order-parameter correlation function at the KT-like transition point is seen to increase from 1/4 as the ratio J_2/J_1 decreases, namely, it reveals a deviation from the universal behavior of a genuine XY model. (27 refs.)

108718 An approximate method for the free energy. J.R.Faleiro Ferreira, N.P.Silva (Dept. de Fisica, Univ. Federal de Minas Gerais, Belo Horizonte, Brazil).
Phys. Status Solidi b (Germany), vol.118, no.2, p.829-33 (1 Aug. 1983).
A variational approximate free energy expression is derived and used to calculate the critical temperature of the anisotropic Ising model. The results are better consistent than others variationally obtained. (7 refs.)

108719 Random field effects in magnets. R.J.Birgeneau (MIT, Cambridge, MA, USA).
Physica B & C (Netherlands), vol.120B+C, no.1-3, p.180-2 (May 1983). (Yamada Conference VI on Neutron Scattering in Condensed Matter, Hakone, Japan, 1-4 Sept. 1982).
Summary form only given. In order to explore the consequences of random field effects the author has carried out a series of neutron scattering experiments on the diluted Ising magnets: $Rb_2Co_{0.7}Mg_{0.3}F_4$, a two-dimensional Ising antiferromagnet; $Co_{1-x}Zn_xF_2$, a three-dimensional Ising antiferromagnet; and $Fe_{1-x}Zn_xF_2$. 75.40F Heisenberg and other quantized spin models

108720 Magnetic behaviour of spin-glass alloys beyond the percolation concentration. A.Mookerjee, S.B.Roy (Dept. of Phys., Indian Inst. of Technol., Kanpur, India).
J. Phys. F (GB), vol.13, no.9, p.1945-54 (Sept. 1983).
Using a mean-field effective medium approach, the authors study the phase diagram of a random Heisenberg model. In particular they study the phases and magnetisation beyond the percolation limit, and compare these with the experimental observations in AuFe alloys with high concentrations of Fe. (20 refs.)

108721 Stability of the Parisi solution for Heisenberg spin glasses. A.V.Goltsev (A.F. Ioffe Phys. Tech. Inst., Acad. of Sci., Leningrad, USSR).
J. Phys. Lett. (France), vol.44, no.16, p.L697-700 (15 Aug. 1983).
For the Heisenberg spin glasses (the Sherrington-Kirkpatrick model) the Parisi solution which preserves a rotative symmetry is considered for the case $H=0$. Existence of massless modes is proved. (11 refs.)

108722 Dipolar interactions in the critical dynamics of Heisenberg ferromagnets. J.Kotzler (Inst. fur Angewandte Phys., Univ. Hamburg, Hamburg, Germany).
Phys. Rev. Lett. (USA), vol.51, no.9, p.833-5 (29 Aug. 1983).
It is shown that in contrast to previous assumptions the real magnetic dipole interaction has to be considered as a possible source of deviations of the dynamical exponent z from $^5/_2$ as observed recently on Fe and Ni. While the dipolar crossover temperatures agree with experiment, at T_c the dynamic crossover around the dipolar wave vector q_d as predicted by current theories is absent. It is argued that this effect is related to a hitherto overlooked dynamical decoupling between transverse and noncritical longitudinal fluctuations if q exceeds the inverse correlation range κ. (24 refs.)

108723 Spin dynamics of two three-dimensional Heisenberg ferromagnets near T_c. W.L.C.Rutten, J.C.Verstelle, N.J.Poulis (Kamerlingh Onnes Lab., Rijksuniv. Leiden, Leiden, Netherlands).
Physica B & C (Netherlands), vol.121B+C, no.3, p.351-69 (Aug. 1983).
An experimental determination and quantitative theoretical analysis will be presented of the macroscopic dynamic susceptibility of $Rb_2CuBr_4.2H_2O$ and $(NH_4)_2CuBr_4.2H_2O$ (two representatives of $S={}^1/_2$, Heisenberg ferromagnetic systems) in the temperature regime of magnetic ordering above T_c. Dynamics will be analysed in terms of the relaxation rate ρ^{-1}. In the theoretical expressions for ρ^{-1}, the macroscopic critical static susceptibility χ_0 plays an important role. Therefore, also χ_0 has been measured as accurately as possible, as well as T_c. Also, attention has been focused on the effect of exchange anisotropy and of dipolar interactions on the wave vector q-dependent relaxation rate $\Gamma(q, T)$. Moreover, the effect of antisymmetric exchange on the critical dynamics has been investigated, as well as the sample shape dependence (demagnetizing effects). Spin dynamics and static susceptibility results outside the critical regime above T_c are not analysed, although briefly presented.

108724 Determination of ferrofluid structure by neutron polarization analysis. R.Pynn, J.B.Hayter (Inst. Max von Laue-Paul Langevin, Grenoble, France), S.W.Charles.
Phys. Rev. Lett. (USA), vol.51, no.8, p.710-13 (22 Aug. 1983).
Neutron polarization analysis is combined with small-angle scattering for the study of a concentrated cobalt ferrofluid. The geometry of the cobalt particle core and surrounding surfactant layer has been determined and an anomalous magnetic layer found at the cobalt surface. The interparticle structure factor, measured for the first time in a magnetically aligned ferrofluid, agrees well with a recent theory. Magnetic fluctuations, measured as a function of applied field, are found to be predominantly paramagnetic. (13 refs.)

75.60 DOMAIN EFFECTS, MAGNETIZATION CURVES, AND HYSTERESIS

108725 Magnetic cluster effects in $FeSi_{1-x}Ge_x$. P.Nordblad, L.Lundgren, O.Beckman (Dept. of Solid State Phys., Inst. of Technol., Uppsala Univ., Uppsala, Sweden).
Phys. Scr. (Sweden), vol.28, no.2, p.246-8 (Aug. 1983).
Magnetization measurements on the solid solution $FeSi_{1-x}Ge_x$ ($x \leq 0.5$) have been performed between 2 and 900K. For low germanium content ($x \leq 0.4$) the susceptibility shows a temperature dependence similar to that of pure FeSi. The susceptibility behaviour of FeSi has previously been interpreted in a localized spin model where a nonmagnetic ground state is separated from a magnetic excited state by a small energy gap. Our experimental results on $FeSi_{1-x}Ge_x$ indicate that the same model is applicable and that the energy gap decreases with an increase of germanium content and becomes zero at $x \simeq 0.6$. Magnetization measurements at low temperatures imply the presence of ferromagnetic clusters. The ordering temperature of the magnetic moments within these clusters is around 60K for $x=0.5$ and about 8K for $x=0.4$. For the germanium richest solid solution ($x=0.5$) we estimate the average cluster size to be 30 μ_B at 4.2K and assuming $S=1$ about 20% of the iron atoms are located within these clusters. (4 refs.)

75.60E Magnetization curves, hysteresis, Barkhausen and related effects

108726 Low-temperature magnetization of amorphous and microcrystalline Co-P alloys. R.S.Iskhakov, G.V.Popov, M.M.Karpenko (L.V. Kirenski Inst. of Phys., Acad. of Sci., Krasnoyarsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.85-93 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A vibrational magnetometer was used to determine the low-temperature magnetization and thus find the exchange interaction parameter α and the saturation magnetization M_O of microcrystalline and amorphous Co-P alloys. The phase diagram of these alloys was determined in terms of the exchange interaction and concentration of P. The region of the composition-dependent transition from a crystalline solid solution to an amorphous alloy was identified. Metastable states were observed in the course of crystallization of amorphous Co-P samples. The composition and topological disorder contributions were found and these were responsible for the changes in the exchange interaction in amorphous Co-P alloys compared with pure Co. It was found that the RMS deviation of fluctuations of the volume could be deduced from the temperature dependence of the macroscopic saturation magnetization. (23 refs.) *A.T.*

108727 Hysteresis and after-effects in massive substances. From spin-glasses to the sand hill. J.Souletie (Centre de Recherches sur les Tres Basses Temperatures, Grenoble, France).
J. Phys. (France), vol.44, no.9, p.1095-116 (Sept. 1983).
Discusses the problem of magnetic hysteresis in the framework of a model of a distribution of thermally activated double well potentials. Having shown the equivalence, at $T=0$, of this description with the classical picture of Preisach (1935) and Neel (1950, 1953), the author considers specifically the effects associated with the fact that the width of the distribution of the barrier-heights is necessarily finite. It is shown how this limit can be introduced in the classical Preisach construction and how it opens the door to the description of aftereffects (in terms of time and of temperature) as well as to the description of the effect of the field beyond the Rayleigh domain. The evolution of the different hysteresis loops of the remanences and susceptibilities are described in terms of field, time and temperature. A particular reference is made to the spin-glass case. The magnetization relaxations at different temperatures ($S(T)$ curves) and the Fulcher law are discussed. Finally, a justification of the Preisach construction is attempted within a language more adapted to the great generality of this construction which successfully applies to magnetic as well as to mechanical hysteresis or to the weight of a sand hill! !... This could be viewed as a first-order approach of nonergodic problems. (42 refs.)

108728 Determination of magnetisation distributions in ferromagnetic terbium and dysprosium. J.Grimm, J.Boysen, W.D.Brewer, G.V.H.Wilson (Fachbereich Phys., Freie Univ. Berlin, Berlin, Germany).
J. Phys. F (GB), vol.13, no.9, p.1931-44 (Sept. 1983).
A theoretical study of the distribution of directions of magnetisation in ferromagnets with sixfold hexagonal anisotropy is presented. The use of various approximate treatments for ferromagnets with a large axial anisotropy, such as terbium and dysprosium, is discussed; the calculated results are compared with magnetisation and nuclear orientation experiments on polycrystalline and single-crystal samples. (16 refs.)

108729 Magnetic studies in amorphous Gd_xY_{1-x} alloys. R.Krishnan, M.Dancygier, M.Laridjani (Lab. de Magnetisme, CNRS, Meudon, France).
J. Magn. & Magn. Mater. (Netherlands), vol.38, no.1, p.78-82 (Aug. 1983).
The authors reports a magnetic study on amorphous Gd_xY_{1-x} alloys with $x=0.17$ and 0.70 and 0.70. The alloy with $x=0.17$ is paramagnetic down to 4.2K. For $x=0.70$, magnetization shows a peak in low magnetic fields ($H<0.3$ T). Magnetic saturation is difficult to obtain even for fields up to 15 T. An extrapolated value gives a moment of 6.2 μ_B/Gd at. T_c is about 70K. This led to the conclusion that ferromagnetic and antiferromagnetic clusters are present in this alloy. The results are discussed by comparing them with crystalline Gd-Y alloys and amorphous Gd-Al, Gd-Au, etc. The effect of Y seems to be specific. (14 refs.)

108730 Mechanisms of magnetic losses in small-grain Ni-Zn ferrites. V.G.Efremov, E.V.Lebedeva, M.A.Kharinskaya (Dept. of Microwave Radiophys., Moscow Univ., Moscow, USSR).
Moscow Univ. Phys. Bull. (USA), vol.37, no.6, p.65-70 (1982). Translation of: *Vestn. Mosk. Univ. Ser. 3 (USSR)*, vol.37, no.6, p.57-62 (1982).
Polycrystalline samples of nickel-zinc ferrites were used to study the dependence of the excitation threshold of spin waves on the grain size. The measurements were carried out on two series of samples. In the first, the zinc concentration was varied to change the anisotropy field, and in the second, the level of internal losses was varied by the introduction of small addition of cobalt ions. It is shown that, as the anisotropy field decreases (the coupling between grains increases) the increase of the threshold field with decreasing grain size becomes weaker. When cobalt ions are introduced, the dependence of the threshold field on the grain size disappears in the region of large grains. (9 refs.)

108731 Temperature dependence and frequency dispersion mechanisms of the magnetic permeability of monocrystalline Mn-Zn ferrite. V.P.Miroshkin, Ya.I.Panova (V.I. Ulyanov (Lenin), Leningrad.Electrical Engng. Inst.,USSR).
Phys. Status Solidi a (Germany), vol.78, no.2, p.K179-82 (16 Aug. 1983).
The magnetic permeability of monocrystalline ferrite with the composition $Mn_{0.7}Zn_{0.25}Fe_{2.05}O_4$ (according to the data of X-ray microanalysis) was investigated. Monocrystalline ferrite was grown by the Verneil technique. For the permeability measurements toroidally shaped specimens, were cut with the axis along the [110] direction. The magnetic permeability measurements were carried out by impedance bridges in the frequency range 1 kHz to 30 MHz and in the temperature interval from −80 to 140°C. (8 refs.)

108732 Effect of thermodynamic fluctuations of magnetization on the bound magnetic polaron in dilute magnetic semiconductors. T.Dietl (Inst. of Phys., Polish Acad. of Sci., Warszawa, Poland), J.Spalek.
Phys. Rev. B (USA), vol.28, no.3, p.1548-63 (1 Aug. 1983).
The authors consider the magnetic field and temperature dependences of the spin splitting for an electron localized on a shallow donor, taking into account the *s-d* coupling with the surrounding magnetic ions. They calculate the probability distribution of the spin splitting Δ with the thermodynamic fluctuations of magnetization included. These are responsible for persistence of the spin splitting at ambient temperature in the absence of the field. The probability distribution of the spin splitting is the main factor determining the energy and the shape of the optical transition line between the spin-split states. These compare their results with recent experimental results on spin-flip Raman scattering in $Cd_{1-x}Mn_xSe$. Their theory provides a satisfactory quantitative description of the donor electron accompanied by a nonuniform cloud of magnetization in that material. (24 refs.)

108733 Changes in the magnetic properties of alloy YuNDKT (35% Co, 15% Ni, 7% Al, 4% Cu, 5% Ti, 1% Nb, rest Fe) during heating. V.I.Sumin, T.P.Alentova.
Russ. Metall. (GB), no.1, p.137-40 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.161-3 (1982).
At elevated temperatures (up to 840°C), alloy YuNDK35T5BA has a high H_c value, above 800 Oe. For alloys YuNDK35T5BA, YuNDK25BA and Fe-Co-Cr, there is either a peak of a plateau on the $H_c(T)$ function in the range of isothermal thermomagnetic treatment. The H_c values calculated on the basis of the Stoner-Wolfarth theory show that the maximum on the $H_c(T)$ function can be explained by the dynamics of the change in I_s, $I_{s\beta}$, p_B and ΔN and the value of the t_c of the β_o phase. The dependence $H_c(I_s)$ can be used in analysing the structure changes in alloys for permanent magnets with shape anisotropy. (7 refs.)

108734 Magnetic properties of calcium-silicates (diopside and gehlenite) doped with iron (III). R.Noller, H.Knoll (Arbeitsgruppe Archaometrie, Inst. fur Anorganische und Analytische Chemie, Freien Univ. Berlin, Berlin, Germany).
Solid State Commun. (USA), vol.47, no.4, p.237-9 (July 1983).
The incorporation of Fe^{3+} cations into some Ca-silicates (diopside, gehlenite), substituting for alkali earths of different valencies and in differently coordinated lattice positions, will give rise to considerable lattice disorder. It is shown that this will result in special magnetization properties of these silicates. (6 refs.)

75.60G High coercivity materials

108735 On the high energy product of Fe-Pt permanent magnet alloys. K.Watanabe, H.Masumoto (Res. Inst. of Electric & Magnetic Alloys, Sendai, Japan).
J. Jpn. Inst. Met. (Japan), vol.47, no.8, p.699-703 (Aug. 1983). In Japanese.
The relations betwen permanent magnetic properties and microstructures of Fe-34-67.5 at.%Pt binary alloys were investigated using a recording fluxmeter, X-ray diffraction and electron microscopy. The excellent permanent magnetic properties have been obtained by water-quenching from a temperature in the γ phase range and subsequent reheating at a lower temperature in the γ_1 phase range. A typical Fe-38.5 at.% Pt alloy exhibits the highest value of maximum energy product of 159 $kJ.m^{-3}$ (20 MG.Oe), with a coercive force of 340 $kA.m^{-1}$ (4.3 kOe) and a residual flux density of 1.08 T (10.8 kG). It is presumed that the excellent permanent magnetic properties are related to the band microstructure of the γ_1 order phase with the $L1_0$-type structure and a high crystal magnetic anisotropy. (15 refs.)

Variation of the magnetic properties of $SmCo_5$ powders by water milling .... See Entry 108740

75.60J Fine-particle systems

108736 Micromagnetism of two-phase quasi-single-domain particles. I.I.Kryokov, N.A.Manakov (Pedagogical Inst., Irkutsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.5-8 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The methods of the theory of micromagnetism are used to study the stability of a homogeneously magnetized state of a two-phase quasi-single-domain particle with a uniaxial magnetic anisotropy. A spherical particle is considered and it is assumed that its surface layer differs from the bulk of the particle in respect of the magnetic anisotropy and exchange interaction constants, and also in respect of the saturation magnetization. An analytic expression is obtained for the critical field needed for the formation of a canted magnetic structure when the surface layer is sufficiently thin. (6 refs.) *A.T.*

108737 Process of magnetization of fine magnetically uniaxial ferromagnetic particles. M.M.Solov'ev (Inst. of Metal Phys., Ural Sci. Center, Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.25-9 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The magnetization curves are calculated for particles which are in the form of a rectangular parallelepiped and consist of two or three domains which repeat the geometric shape of the sample. The effects of the size and shape of the particles are considered. The characteristics of the magnetic behaviour of the particles with this type of domain structure are studied and the stability is considered. (10 refs.) *A.T.*

108738 Theory of agglomeration of ferromagnetic particles in magnetic fluids. K.Sano, M.Doi (Dept. of Phys., Tokyo Metropolitan Univ., Tokyo, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2810-15 (Aug. 1983).
For some magnetic fluids, large agglomerates of magnetic particles are formed when a weak magnetic field is applied. The authors regard this phenomenon as a kind of gas-liquid phase transition induced by the magnetic field, and study the condition for the formation of the agglomerates by a simple mean field theory. It is found that if the particle is small enough, no phase separation occurs even if the magnetic field is infinitely large, while if the particle is large, the liquid phase appears at certain magnetic field. The van der Waals attraction between the particles enhances the agglomeration. (15 refs.)

108739 Magnetic components and particle size distribution of coal flyash. G.Chaddha, Mohindar S. Seehra (Dept. of Phys., West Virginia Univ., Morgantown, WV, USA).
J. Phys. D (GB), vol.16, no.9, p.1767-76 (14 Sept. 1983).
The results of a detailed study into the nature and concentration of magnetic components as a function of particle size in five flyash samples of bituminous coals are reported. Samples were size-fractioned into ten fractions each using sieves and temperature-dependent magnetisation studies were used to determine the magnetic components. Observation of the Verwey transition near 120K and an anomaly near 250K in the magnetisation indicate the presence of Fe_3O_4 and α-Fe_2O_3 respectively. Confirmatory evidence for the presence of these minerals was obtained from X-ray diffraction studies of the samples. Magnetic components and mass distribution were determined as a function of particle size and it is found that about half the mass and magnetic components are contained in the fraction with the smallest particles (diameter ≤ 38 μm). Based on the variation of the saturation magnetisation M_s with particle size, the five samples can be classified into two groups: group I of three samples for which M_s falls off with increasing particle size and group II of two samples for which M_s is nearly constant with particle size. Other similarities within each group are: (i) nearly equal levels of Fe_3O_4 and α-Fe_2O_3 in group I whereas in group II, α-Fe_2O_3 has nearly four times the concentration of Fe_3O_4 and (ii) group II has a much higher level of unburnt carbon than group I. Correlations between these observations and combustion conditions of flyash are discussed and their possible applications are outlined. (15 refs.)

108740 Variation of the magnetic properties of $SmCo_5$ powders by water milling. E.Konig (Wissenschaftsbereich Phys., Hochschule fur Verkehrswesen 'Friedrich List', Dresden, Germany).
Phys. Status Solidi a (Germany), vol.78, no.2, p.K159-60 (16 Aug. 1983).
The process of grinding of $SmCo_5$ pieces takes place under a protective liquid. The protective liquid in the vibration mill has been varied: the milling medium benzene was compared with water. Initial material was a $SmCo_{4.7}$ powder with particle diameters of ≤ 0.25 mm. After grinding, powder samples were prepared in air. Employing the medium benzene the intrinsic coercitivity ${}_iH_c$ rises after a milling time of 5.5 h from 13×10^4 Am^{-1} to 131×10^4 Am^{-1}, while the specific saturation magnetization σ decreases from 10.94×10^{-5} $Vsmkg^{-1}$ to 10.57×10^{-5} $Vsmkg^{-1}$. The oxygen content amounts to 1.2 wt.%. In the case of water the oxygen of the powder specimens now reaches after the same time 6.5 wt.%. These samples show a lower specific saturation magnetization $\sigma=9.22\times10^{-5}$ $Vsmkg^{-1}$, but surprisingly a higher coercitivity ${}_iH_c=154\times10^4$ Am^{-1}. (5 refs.)

75.70 MAGNETIC FILMS AND PLATES

108741 Large uniaxial magnetic anisotropy in amorphous Tb-Fe evaporated thin films. H.Kobayashi, T.Ono, A.Tsushima (Dept. of Appl. Phys., Waseda Univ., Tokyo, Japan), T.Suzuki.
Appl. Phys. Lett. (USA), vol.43, no.4, p.389-90 (15 Aug. 1983).
Magnetic properties of amorphous Tb-Fe alloy films have been investigated for magneto-optic memory media applications. The perpendicular magnetic anisotropy, saturation magnetization, and Curie temperature were investigated in the samples deposited by vacuum evaporation at different substrate temperatures *Ts*. A very large value (2×10^7 erg/cc) of the uniaxial anisotropy constant *Ku* was found in the samples deposited at a high substrate temperature (400°C), and it was found also that the saturation magnetization and Curie temperature exhibit a strong dependence on substrate temperature during the evaporation process. (3 refs.)

108742 Magnetic properties and structure of cobalt-platinum thin films. J.A.Aboaf, S.R.Herd, E.Klokholm (Thomas J. Watson Res. Center, Yorktown Heights, NY, USA).
IEEE Trans. Magn. (USA), vol.MAG-19, no.4, p.1514-19 (July 1983).
The magnetic properties of RF sputtered Co-Pt alloy thin films were studied as a function of Pt content from 0 to 80 at%. At room temperature, ferromagnetic films were obtained in the range 0-32 and 40-80 at% Pt. For Pt contents between 32 and 40 at%, discontinuities in the magnetization, magnetostriction, and coercivity versus Pt content were observed; however no discontinuity was observed in the resistivity. The structure of films containing about 25 at% Pt is a mixture of hexagonal and face-centered cubic (FCC) phases. At this composition the magnetostriction is small, but coercivities are large—700 to 2000 Oe—and dependent upon film thickness. The coercivities of these films do not change with heat treatment up to temperatures of 600°C but decrease markedly at 700°C. The properties of equiatomic Co-Pt films are similar to those of bulk alloys. In particular the large coercivity observed in films after heat treatment at 500° to 700°C is due to the formation of an ordered tetragonal phase within the face-centered cubic matrix. The structure of films of about 75 at% Pt is initially a disordered face-centered cubic phase and with heat treatment beginning at 500°C an ordered face-centered cubic phase forms. The coercivity of these films (~200 Oe) does not change with annealing at 500°C. It decreases slightly upon further annealing at 600° to 700°C. Electron microscope observations were used to correlate the magnetic properties with film structure. (7 refs.)

108743 Magnetic properties of amorphous sputtered Co_xSi_{1-x} films. J.M.Alameda, J.M.Gonzalez, F.Lopez, J.L.Vicent (Lab. de Magnetismo, Univ. Complutense, Madrid, Spain).
J. Magn. & Magn. Mater. (Netherlands), vol.38, no.1, p.105-8 (Aug. 1983).
Magnetic properties have been measured by transverse magneto-optic Kerr effect (MOKE) in amorphous sputtered Co_xSi_{1-x} films which are ferromagnetic and amorphous at room temperature with $0.55<x<0.80$. These as-sputtered films show an in-plane easy axis with the ratio of coercive force in the hard axis H_c (HA) to easy axis H_c (EA) and the value of the blocking field H_B almost constant with $0.60<x<0.80$. Transverse magnetic susceptibilities with bias magnetic field parallel (χ_{t0}) and perpendicular ($\chi_{t\pi/2}$) to the easy axis has been measured. These measurements show a deviation of Hoffmann's (1969) micromagnetic law for the susceptibilities. (12 refs.)

75.70K Domain structure (magnetic bubbles)

108744 Propagation of magnetic bubbles on ion implanted patterns in a (100) Bi-yttrium iron garnet film. R.Wolfe, L.C.Luther, R.C.LeCraw, R.A.Lieberman (Bell Labs., Murray Hill, NJ, USA).
Appl. Phys. Lett. (USA), vol.43, no.3, p.322-4 (1 Aug. 1983).
Magnetic bubbles have been propagated on ion implanted patterns in a (100) garnet film for the first time. Charged walls form in the implanted layer at the edges of unimplanted features due to stress relief at the pattern edges. In response to a rotating in-plane field, they circulate completely around unimplanted circles and 8-μm contiguous disk patterns, carrying underlying bubbles along. This is because in the Bi-yttrium iron garnet composition used, the magnetostriction coefficients λ_{100} and λ_{111} are both negative. (10 refs.)

108745 Stripe domains in polycrystalline Fe thin films obtained from thick foils. V.Rivera, R.Valenzuela (Inst. de Investigaciones en Materiales, Univ. Nacionale Autonoma de Mexico, Mexico City, Mexico).
KINAM Rev. Fis. (Mexico), vol.5, no.2, p.185-7 (1983).
The stripe domain structure has been explained by Saito et al. (1964) on the basis of an induced uniaxial anisotropy which is not contained within the plane of the film, although the mechanisms for the existence of the anisotropy in the evaporated film are not fully understood. As a result, the magnetization experiences wavelike deviations from the plane of the film. The authors report some stripe domains observed on (111) planes in polycrystalline Fe thin films obtained from thick foils by electropolishing, by means of Lorentz electron microscopy. (7 refs.)

108746 Influence of a magnetic suspension on the domain structure of ferromagnetic films of various thicknesses. B.A.Avramenko, L.I.Lukashenko, L.S.Palatnik, A.G.Shishkov (V.I. Lenin Polytech. Inst., Kharkov, Ukrainian SSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.66-71 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of the influence of a magnetic suspension on the dependence of the number n of transverse links in a domain wall on the thickness t of ferromagnetic permalloy films. It was found that a magnetic suspension shifted the dependence n(t) towards higher value of t, increasing thus the stability of Neel walls. An analysis is made of the processes of formation of helical domain structures and of wall doubling. A scheme explaining the appearance of such structures in the presence of a magnetic suspension is put forward. (13 refs.) *A.T.*

108747 The influence of stress relaxation on charged walls in a (100)-oriented garnet film. D.A.Saunders, M.H.Kryder (Electrical Engng. Dept., Carnegie-Mellon Univ., Pittsburgh, PA, USA).
IEEE Trans. Magn. (USA), vol.MAG-19, no.4, p.1505-8 (July 1983).
Planar domain configurations in a (100) garnet film indicate the presence of inverse magnetostrictive anisotropies along boundaries between implanted and unimplanted regions of the film. Stress relief at such boundaries has been cited as an important factor in the formation of charged walls in (111) films. The domains seen in this (100) film illustrate dramatically the effect of this stress relief. The stress is modeled as a uniaxial stress which gives rise to uniaxial anisotropies along the boundary. Because $\lambda_{100}$and λ_{111} are of different signs, the easy axis of magnetization is found to alternate perpendicular to and parallel to the boundary around an implanted disk. It is conjectured that (100) films with λ_{100} and λ_{111} of the same sign may successfully support charged walls suitable for bubble propagation. (8 refs.)

108748 Bubble film characterization by differential susceptibility measurements. P.Novotny (Inst. of Phys., Czechoslovak Acad. of Sci., Prague, Czechoslovakia).
Phys. Status Solidi a (Germany), vol.78, no.2, p.K101-4 (16 Aug. 1983).
Describes a simple equipment proposed and built up for collapse field measurements of magnetic bubble materials. The differential susceptibility is measured by an induction method and the stripe collapse field H_{sc} is determined. It is shown that static parameters derived from the results agree with those obtained independently by optical measurements. (8 refs.)

108749 Observation of magnetic bubbles by Lorentz electron microscopy. D.Watanabe, T.Sekiguchi.
Solid State Phys. (Japan), vol.18, no.5, p.255-64 (May 1983). In Japanese.
Recent studies of magnetic bubbles in HCP cobalt, hexaferrite crystals and magnetic thin films with perpendicular anisotropy observed by means of Lorentz electron microscopy are reviewed. (24 refs.)

75.80 MAGNETOMECHANICAL AND MAGNETOELECTRIC EFFECTS, MAGNETOSTRICTION

108750 Magnetic and magnetoelastic properties of compounds $Tb(Fe_{1-x}Pt_x)_2$. V.F.Novikov, L.V.Apsitis, R.S.Gamidov (Lenin Komsomol Industrial Inst., Tyumen, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.77-9 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
Magnetic and magnetoelastic properties of alloys of the quasibinary system $Tb(Fe_{1-x}Pt_x)_2$ were investigated. The laws governing the dependences of the magnetostriction, magnetization, and coercive force on the platinum content were determined at room temperature. (13 refs.) *A.T.*

108751 Laws of approach to magnetic saturation for interacting and isolated spherical and cylindrical defects in isotropic magnetostrictive media. A.P.Malozemoff (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA).
IEEE Trans. Magn. (USA), vol.MAG-19, no.4, p.1520-3 (July 1983).
Laws of approach to magnetic saturation are derived for interacting spherical and cylindrical defects in isotropic magnetostrictive media like amorphous materials. The normalized longitudinal magnetic deviation $\Delta M/M$ goes as $1/H^2$ for both cases, provided all defects have the same sign. For randomly signed defects, $1/H^{5/4}$ and $1/H^{3/2}$ laws are derived for spheres and cylinders, respectively. Isolated cylindrical defects obey a $1/H$ or $1/H^2$ law depending on whether the defect is small or large compared to an exchange length. (11 refs.)

108752 Effects of compressive stress perpendicular to the surface of four percent silicon-iron single crystals. T.Hiramatsu (Faculty of Engng., Oita Tech. Coll., Oita, Japan), K.Narita.
IEEE Trans. Magn. (USA), vol.MAG-19, no.4, p.1562-4 (July 1983).
Effects of compressive stress perpendicular to the surface of 4 percent silicon-iron single crystals on their magnetic properties were investigated. Picture frame single crystal specimens which were used had [100] and [111] orientation, respectively. The hysteresis loops at low field ($0<H<450$ A/m) were measured under the applied stress. For the 4 percent Si-Fe [100] specimen, a large decrease of induction under stress occurs at lower fields, and for the 4 percent Si-Fe [111] specimen, the induction increases with increasing applied stress at lower fields but decreases at higher fields and coincides with the same value of the zero stress case when H is greater than about 400 A/m. The stress versus B_r/B_m curves of the 4 percent Si-Fe [100] and [111] specimens were plotted to show the change of the induction under applied stress. (4 refs.)

108753 Stress induced magnetization changes of steel pipes—laboratory tests. D.L.Atherton, L.W.Coathup, D.C.Jiles, L.Longo, C.Welbourn (Dept. of Phys., Queen's Univ., Kingston, Ontario, Canada), A.Teitsma.
IEEE Trans. Magn. (USA), vol.MAG-19, no.4, p.1564-8 (July 1983).
Magnetometer surveys above gas pipelines show stress induced magnetic anomalies at pipe bends. This suggests a potential technique for the noninvasive monitoring of stress in buried pipelines, etc. Laboratory measurements of the magnetic field changes due to the elastic bending of 110 mm diameter pipe are presented. The effects of oreientation with respect to the earths field and of internal pressure are reported. Hysteretic effects are found to be important. (5 refs.)

108754 Influence of plastic deformation on magnetic interaction in $FePt_3$ alloy. S.Takahashi (Faculty of Engng., Iwate Univ., Morioka, Japan), K.Ikeda.
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2772-6 (Aug. 1983).
It was found that in the long range ordered $FePt_3$ alloy, which showed no ferromagnetism before plastic deformation, the application of cold work caused it to become quite strongly ferromagnetic. The mechanism of transition from antiferromagnetic to ferromagnetic coupling by plastic deformation has been elucidated in terms of dislocation theory with consideration of ferromagnetic and antiferromagnetic Fe-Fe interactions. It has been proposed that the Fe atoms at the Pt-sites, being ferromagnetically coupled, is proportional to the dislocation density at the early stage of plastic deformation and its square root at the advanced stage.

108755 Magnetostriction of dilute rate-earth bismuthides: the effect of non-S-state ions versus 'S-state' ions. H.U.Hafner, D.Davidov (II Phys. Inst., Univ. zu Koln, Koln, Germany), G.J.Nieuwenhuys.
J. Magn. & Magn. Mater. (Netherlands), vol.38, no.1, p.45-50 (Aug. 1983).
Shape magnetostriction measurements along the [001] direction were carried out for dilute rare-earth bismuthides; LaBi:R (R=Ce, Sm, Gd, Tb, Er) and the antimonide LaSb:Gd. The magnetostriction of LaBi:Ce and LaBi:Sm reveal the 'reverse magnetostriction' phenomenon, enabling the authors to extract an overall crystalline field splitting of 12K for the former compound. The magnetostriction of LaBi:Gd and LaSb:Gd which are significantly larger than that of the 'pure' hosts, can be explained by a modified version of a model previously suggested by them. The fitting procedure yields magnetoelastic coupling constants for LaSb:Gd and LaGi:Gd which have the correct sign and magnitude according to existing theories. (14 refs.)

76.00 MAGNETIC RESONANCES AND RELAXATION IN CONDENSED MATTER; MÖSSBAUER EFFECT

(for measurement techniques, see 07.58)

76.20 GENERAL THEORY OF RESONANCES AND RELAXATION

108756 Two-dimensional reorientation and magnetic resonance line shapes in semiordered solids. R.G.Kooser (Dept. of Chem., Knox Coll., Galensburg, IL, USA), H.A.Resing.
J. Phys. Chem. (USA), vol.87, no.14, p.2564-74 (7 July 1983).
For systems expected to exhibit a 2-DPAP (two-dimensional powder anisotropy pattern) modulated by fixed-angle reorientation, explicit model-dependent features are present in the near-rigid limit in the form of subsidiary peaks. The location of these peaks can be used to specify the microscopic reorientation model except in the pairs 2-4- and 3-6-site jumping. The advantage of the two-dimensional powder patterns over the previously published three-dimensional powder spectra is that the symmetry can be read directly from the location of the subsidiary peaks and spectral simulation may not be needed. This suggests that, where possible, systems be examined in the 2-DPAP mode. In the narrowed region, as is well-known from exchange theory, the line widths are determined by a correlation time. The authors have shown how to relate this correlation time to the jump probability from a given state, thus again extracting the details of the microscopic model from magnetic resonance techniques. (33 refs.)

76.30 ELECTRON PARAMAGNETIC RESONANCE AND RELAXATION

108757 Single-crystal EPR of the ^{17}O-enriched dioxygen adduct of vitamin B_{12r}: reversible oxygen bonding, electronic and geometric structure, and molecular dynamics. E.Jorin, A.Schweiger, H.H.Gunthard (Lab. for Phys. Chem., Swiss Federal Inst. of Technol., Zurich, Switzerland).
J. Am. Chem. Soc. (USA), vol.105, no.13, p.4277-86 (29 June 1983).
Single-crystal EPR studies on the oxygen adduct of vitamin B_{12r} and on the thermodynamics of the oxygenation process of B_{12r} were carried out on vitamin B_{12b} crystals doped with B_{12r} and $B_{12r}O_2$. For the determination of the spin density on the dioxygen, some of the crystals were enriched to about 25% in ^{17}O. EPR spectra of $B_{12r}O_2$ between -160 and 40°C were recorded in three perpendicular planes defined by the crystallographic coordinate system a,b,c of the B_{12b} host crystal (space group $P2_12_12_1$). At -160°C, the **g** tensor and the two oxygen hyperfine tensors of $B_{12r}O_2$ are coaxial with the largest g principal axis along the O_α-O_β bond, whereas one of the principal axes of the cobalt hyperfine tensor is oriented approximately along the corrin normal. In this low-temperature modification the dioxygen molecule was locked in a single minimum potential. The Co-O_α-O_β moiety was bent with a bond angle of 111°. The projection of the O_α-O_β direction on the corrin ring lies between rings B and C and approximately bisects the angle N22-Co-N23. The magnetic parameters of the low-temperature modification were discussed in detail within the spin-pairing and the superoxide formulation models. A total spin density on the dioxygen of $\rho(O_2)=0.7\pm0.1$ has been calculated. Drastic temperature-dependent changes in the **g** and $\mathbf{A}^{Co}$ tensors of $B_{12r}O_2$ with respect to axes directions and principal values were observed. (59 refs.)

108758 Experimental methods to determine the microwave field strength in electron spin resonance. A.I.Vistnes (Inst. of Phys., Univ. of Oslo, Oslo, Norway), L.R.Dalton.
J. Magn. Resonance (USA), vol.54, no.1, p.78-88 (Aug. 1983).
Two simple methods for determining the microwave magnetic field at the sample position in ESR spectroscopy are presented. The first method is based on the magnetization hysteresis spectrum obtained from a combination of the in-phase and out-of-phase spectra. The other method is based on the power dependent linewidth. In both cases a tiny crystal of NMP-TCNQ is used that can easily be placed inside a flat cell or a capillary. The methods based on NMP-TCNQ can be used in a wider temperature range compared to methods based on an aqueous solution of PADS. Thus, temperatures below 0°C are attainable which in turn can be useful, e.g. in saturation transfer ESR experiments on model systems. (19 refs.)

108759 Electron paramagnetic resonance of the eclipsed layered compounds $NH_3(CH_2)_nNH_3CuBr_4$ with $n=2, 3, 4$. T.M.Kite, J.E.Drumheller (Dept. of Phys., Montana State Univ., Bozeman, MT, USA).
J. Magn. Resonance (USA), vol.54, no.2, p.253-6 (Sept. 1983).
The EPR of the eclipsed layered compounds alkane diammoniumtetrabromocuprate, $NH_3(CH_2)_nNH_3CuBr_4$, with $n=2$, 3, and 4 has been studied in the temperature range 113 to 296K. The angular dependence of the linewidths is explained by the use of the static spin correlations with emphasis on the extraction of the anisotropies and to confirm the expected departure from two-dimensional magnetism. A discussion of the static spin correlation effects including a possible explanation of the usual linear temperature dependence is included. Comparisons are made to the structurally isomorphic chloride salts. (11 refs.)

Two-dimensional reorientation and magnetic resonance line shapes in semiordered solids .... See Entry 108756

76.30D Ions and impurities: general

108760 The angular dependence of EPR spectra for ions with $S=3/2$ in a crystal field of rhombic symmetry in the case of large zero-field splittings. A.K.Petrosyan.
Izv. Akad. Nauk Arm. SSR Fiz. (USSR), vol.17, no.1, p.15-21 (1982). In Russian.
In the case of large zero-field splittings analytic expressions for the angular dependence of energy levels for ions with $S=3/2$ in crystal fields of rhombic symmetry have been obtained to an accuracy of the second order of perturbation theory. Taking account of the Zeeman interaction the correct wave functions of spin levels were calculated and simple formulas for the $\lambda=E/D$ parameter were obtained. These formulas allowed the author to determine the D and E parameters of fine structure when the value of zero-field splitting was known. (9 refs.)

108761 Evaluation of spin Hamiltonian parameters of electron-nuclear spin-coupled systems from EPR data by the method of least-squares fitting. S.K.Misra (Phys. Dept., Concordia Univ., Montreal, Canada).
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.193-201 (1983).
Details of a rigorous least-squares fitting procedure for the evaluation of spin-Hamiltonian parameters from EPR data for electron-nuclear spin-coupled systems are given. In this method, all EPR line positions corresponding to several orientations of the external magnetic field are simultaneously fitted. Feynman's theorem is used in order to employ numerical techniques on a digital computer for the required calculations. Details are provided of the steps taken to minimize the computer time, as well as to achieve the convergence of the iterative procedure. The procedure is illustrated by application on the X-band room temperature EPR data obtained for the electron-nuclear spin-coupled system of Mn^{2+} doping single crystal of $ZnSiF_6.6H_2O$. (17 refs.)

76.30F Iron group (3d) ions and impurities (Ti-Cu)

108762 EPR investigation of $(NH_4)_3H(SO_4)_2$ crystals doped with VO^{2+} ion. J.Minge, S.Waplak, L.Szczepanska (Inst. of Molecular Phys., Polish Acad. of Sci., Poznan, Poland).
Acta Phys. Pol. A (Poland), vol.A64, no.2, p.151-60 (Aug. 1983).
EPR is used for determining coordination and spin-Hamiltonian parameters of VO^{2+} in $(NH_4)_3H(SO_4)_2$ for both single-domain and multi-domain specimens and to determine the number of magnetically and physically equivalent complexes of VO^{2+}. It is shown that the impurity ion VO^{2+} takes interstitial position surrounded by 4 oxygen atoms, originating from 4 sulphur and two NH_4^+(II) ions. The polar VO^{2+} z-axis is parallel to the axis connecting two nearest NH_4^+(II) vacancies. As a result the +2 excess charge of VO^{2+} ion is compensated. In the single domain sample there are two physically nonequivalent VO^{2+} complexes. (21 refs.)

108763 Electronic paramagnetic resonance of the mineral metatorbenite. J.M.Diaz (Dept. de Fisica, Univ. Nacional de Colombia, Bogota, Colombia).
Rev. Colomb. Fis. (Colombia), vol.15, no.1, p.107-13 (1981). In Spanish. [received: Aug. 1983]
This mineral contains uranium, copper and phosphorus; the paramagnetic properties of copper enable this electronic resonance method to be used; the width of the resonance lines varies between 20 and 34 gauss, in contrast with the calculated value of 96 gauss. The discrepancy is explained on the hypothesis that the copper atoms are positioned in planes with a relatively large separation thus forming a two-dimensional magnetic system. (9 refs.)
N.C.

108764 Paramagnetic centres created by a thermal treatment in potassium dichromate crystals. A.A.Alybakov, V.A.Gubanova, K.Kudabaev, N.Tojchiev (Inst. of Phys. & Math., Acad. of Sci., Frunze, Kirghiz SSR).
Cryst. Res. & Technol. (Germany), vol.18, no.7, p.K68-70 (1983).
As grown $K_2Cr_2O_7$ crystals show no EPR absorption since chromium is in nonparamagnetic sixvalent state. Thermal treatment of these crystals results in the creation of paramagnetic centres. For an arbitrary crystal orientation EPR spectrum shows two groups of lines, each group consisting of two lines with the same intensity disposed close to each other. The obtained correlation between the principal g-values ($g_z<g_x$, g_y) indicates that Cr^{5+} ions in centres, responsible for the observed EPR spectra, are in heavily distorted tetrahedral surroundings. (7 refs.)

108765 Spin quenching and EPR of Mn^{2+} in $K_2Ni(SeO_4)_2.6H_2O$ single crystals. R.K.Malhotra, V.P.Seth, V.K.Jain (Dept. of Phys., Maharshi Dayanand Univ., Rohtak, India).
Can. J. Phys. (Canada), vol.61, no.9, p.1359-61 (Sept. 1983).
Anelectron paramagnetic resonance study of Mn^{2+} in $K_2Ni(SeO_4)_2.6H_2O$ single crystals has been made at 294K and 9.45 GHz. The Mn^{2+} substitutes at Ni^{2+} sites in the lattice. The spin-Hamiltonian parameters are evaluated. The observations regarding the anisotropic and field dependent line widths of Mn^{2+} in the lattice are discussed using the spin-quenching concept. (6 refs.)

108766 Low-spin ferric porphyrin complexes: analysis of the electronic structure based on single-crystal electron spin resonance measurements. M.P.Byrn, B.A.Katz, N.L.Keder, K.R.Levan, C.J.Magurany, K.M.Miller, J.W.Pritt, C.E.Strouse (Dept. of Chem. & Biochem., Univ. of California, Los Angeles, CA, USA).
J. Am. Chem. Soc. (USA), vol.105, no.15, p.4916-22 (27 July 1983).
Single-crystal electron spin resonance **g** tensor determination for a low-spin ferric porphyrin complex can provide both an accurate description of spin distribution and a quantitative characterization of the axial ligand binding. Experimental **g** tensor determinations for a series of six low-spin (tetraphenylporphinato)iron(III) thiolate complexes illustrate the simple, but not intuitive, relationship between the orientation of the principal axes of the **g** tensor and the spin distribution. The axial thiolate ligands in this series of complexes cover a relatively wide range of σ-donor strength. Analysis of the crystal field parameters obtained from the principal g values reveals an excellent correlation between the tetragonality (Δ) and the pK_a of the corresponding thiol. On the other hand, the rhombicity (V/Δ) for this series of complexes is virtually independent of σ-donor strength of the axial ligand. (39 refs.)

108767 Magnetic anisotropy of copper(II) complexes from ESR studies in solution. Use of mixed ligand complexes. R.Das, B.S.Prabhananda (Chemical Phys. Group, Tata Inst. of Fundamental Res., Bombay, India).
J. Magn. Resonance (USA), vol.54, no.1, p.89-98 (Aug. 1983).
ESR linewidths of the complex $Cu(Q)_2$ and that of the mixed ligand complex Cu(P)(Q) in liquid solution, where P and Q are two different ligand groups, can be used to determine or confirm the anisotropy of $Cu(Q)_2$, when the anisotropy parameters associated with $Cu(P)_2$ are known. This method makes use of (i) the equations derived by Kivelson and coworkers (Wilson and Kivelson, J.Chem. Phys., vol.44, p.154, 19,66; Atkins and Kivelson, J.Chem. Phys., vol.44, p.169 1966); (ii) equations which find justification in the model proposed by Kuska and coworkers (Kuska, Rogers, and Drullinger, J.Phys. Chem., vol.71, p.109, 1967; Kuska, J.Am. Chem. Soc., vol.97, p.2289, 1975) to explain the variation of metal hyperfine constant. The procedure is shown to be promising by taking the example of Cu $\{(i\text{-}C_3H_7O)_2PSe_2\}_2$. This method could be useful when it is difficult to obtain good frozen solutions/single crystal ESR spectra. (17 refs.)

108768 Intrinsic paramagnetic dimers in the Magneli titanium oxides. S.A.Fairhurst, A.D.Inglis, Y.Le Page, J.R.Morton, K.F.Preston (Div. of Chem., Nat. Res. Council of Canada, Ottawa, Ontario, Canada).
J. Magn. Resonance (USA), vol.54, no.2, p.300-4 (Sept. 1983).
An intense EPR spectrum observed between 90 and 150K in single crystals of Ti_5O_9, Ti_6O_{11}, Ti_7O_{13}, and Ti_8O_{15} attributed to Ti_2^{7+} oxygen-bridged dimers present as intrinsic components of the crystal structures. Very much weaker EPR signals detected in Ti_4O_7 and Ti_9O_{17} are attributed to defect species. (9 refs.)

108769 EPR study of the randomly diluted two-dimensional Heisenberg ferromagnet $K_2Cu_xZn_{1-x}F_4$. I.Yamada, S.Shimoda, S.Nagano (Dept. of Phys., Faculty of Sci., Chiba Univ., Chiba, Japan).
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.127-33 (1983).
The authors report a room temperature EPR study of $K_2Cu_xZn_{1-x}F_4$, a randomly site-diluted system of the two-dimensional Heisenberg ferromagnet K_2CuF_4. Since the ferromagnetism of K_2CuF_4 comes from the orbital ordering of $d(z^2-x^2)$ and $d(z^2-y^2)$ due to the cooperative Jahn-Teller distortion of F^--octahedra, particular attention has been paid to the x-dependences of g-values in order to see how the orbital ordering is disturbed by Zn^{2+} ions which have no Jahn-Teller effect. From the almost unchanged g-values obtained for $x\geq0.4$, they infer that the orbital ordering remains for $x\gtrsim0.4$, which assures the in-plane exchange interactions to be ferromagnetic over this range of x. Both the linewidth of the main-line and the intensity of the satellite ($2\omega_0$)-line show different aspects above and below $x\simeq0.4$. This value of x coincides with the percolation limit 0.41 for the next-nearest-neighbor interactions on a square lattice. Taking account of the appearance of T_c for $x<0.59$, the percolation limit for the nearest-neighbor interactions, observed in the susceptibility-measurement by Okuda et al. (1980), they conclude that $x\simeq0.4$ should be the critical concentration and thus the next-nearest-neighbor exchange plays an important role in the present diluted system. (15 refs.)

108770 ESR fields as a function of temperature in the quasi one-dimensional Heisenberg $S={}^1/_2$ ferromagnets $[C_6H_{11}NH_3]CuCl_3$ and $[C_6H_{11}NH_3]CuBr_3$. R.Hoogerbeets, A.J.Van Duyneveldt (Kamerlingh Onnes Lab., Rijksuniv. Leiden, Leiden, Netherlands).
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.233-6 (1983).
The 18.3 GHz ESR fields of $[C_6H_{11}NH_3]CuCl_3$ and $[C_6H_{11}NH_3]CuBr_3$ as a function of temperature (4.2-40K) are reported. Large shifts of these fields were found. It is shown that the anisotropy in the intrachain exchange interaction determines these field shifts. (7 refs.)

108771 EPR and magnetic susceptibility studies of xCuO.(1-x)[2B_2O_3.PbO] glasses. I.Ardelean, O.Cozar, G.Ilonca (Faculty of Phys., Univ., of Cluj-Napoca, Cluj-Napoca, Rumania).
Rev. Roum. Phys. (Rumania), vol.28, no.5, p.451-7 (1983).
X-ray analysis, EPR and magnetic susceptibility measurements have been performed on xCuO.(1-x)[2B_2O_3.PbO] glasses with $0 \leq x \leq 55$ mol.%. The modification of the EPR spectra with the increase of CuO content are explained supposing that they are the results of the superposition of two EPR signals, one showing the hyperfine structure typical of isolated copper ions and other consisting from a broad line centred at $g \simeq 2$, typical of clustered ions. Beside the dipole-dipole coupling between copper ions, the magnetic measurements suggest that for $x>5$ mol.% CuO the superexchange interactions appear to. From the Curie constant values the authors have established that in these glasses both Cu^{2+} and Cu^{+} ions are present. (24 refs.)

108772 Electron paramagnetic resonance of VO^{2+} in $Cs_2C_2O_4.H_2O$ single crystals. R.K.Malhotra, V.P.Seth, V.K.Jain (Dept. of Phys., MD Univ., Haryana, India).
Solid State Commun. (USA), vol.47, no.9, p.721-2 (Sept. 1983).
The electron paramagnetic resonance of VO^{2+} in cesium oxalate monohydrate has been studied in X-band and at 290K. The VO^{2+} occupies two magnetically inequivalent sites in the lattice and exhibits rhombic symmetry. The values of dipolar coupling constant and Fermi contact coupling parameters are evaluated. (14 refs.)

108773 Structure of active centers in manganese-doped single crystals of yttrium titanate $Y_2Ti_2O_7$. K.A.Kuvshinova, M.L.Meil'man, A.G.Smagin, R.Yu.Abdulsaribov, V.A.Antonov, P.A.Arsen'ev, L.B.Pasternak (All-Union Correspondence Engng.-Construction Inst., USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.2, p.198-202 (March-April 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.2, p.339-45 (March-April 1983). [received: Sept. 1983]
Crystals of $Y_2Ti_2O_7$(Mn), grown by zone melting in an optical beam in air, are investigated by means of optical and ESR spectroscopy. The ESR spectrum observed at 300K is attributed to transitions between sublevels of the ground state $^4A_2$ of quadrivalent manganese ions which isomorphically replace Ti^{4+} ions in positions of type c ($G_c=3m$); the spectrum is described by a spin-Hamiltonian of axial symmetry. $\hat{H}=\beta HgS+1/3DO_2{}^0+SAJ$, with parameters $g_{\parallel}=1.9895(5)$, $g_{\perp}=1.9987(7)$, $|D|=0.967(6)$, $|A_{\parallel}|=68.0(5)\times10^{-4}$, $|A_{\perp}|=105.0(5)\times10^{-4}$ cm^{-1}. The band of red photoluminescence at 655-695 nm (77K) is attributed to the spin-forbidden transitions $^2E \rightarrow {}^4A_2$ of Mn^{4+} ions, which are responsible for the ESR spectrum. An intense, broad absorption band at 505 nm is attributed to the $^5E_g \rightarrow {}^5T_{2g}$ transitions of trivalent manganese ions, which isomorphically replace Y^{3+} ions in positions of type d (G_d=3m). It is shown that the interpretation of the data obtained previously from spectroscopic investigations of manganese-activated oxide crystals of corundum Al_2O_3, strontium titanate $SrTiO_3$, and garnet $Y_3Al_5O_{12}$ is ambiguous, and evidently requires revision. 108774 ESR studies of electron irradiated $K_3Ir(CN)_6$ in KCl single crystals. Mono and di-chlorinated species. N.V.Vugman, N.M.Pinhal (Inst. de Fisica, Univ. Federal do Rio de Janeiro, Rio de Janeiro, Brazil).
Mol. Phys. (GB), vol.49, no.6, p.1315-19 (20 Aug. 1983).
ESR studies of KCl single crystals doped with small amounts of $K_3Ir(CN)_6$ and submitted to a prolonged 2 MeV electron irradiation at room temperature reveal the presence of the species $[Ir(CN)_5Cl]^{4-}$ and $[Ir(CN)_4Cl_2]^{4-}$. Ligand spin densities and ligand field parameters are calculated from the experimental hyperfine and superhyperfine interactions and compared with previous data on the species $[Ir(CN)_5]^{4-}$. 108775 Diffusion of free radicals as studied by tomography. E.V.Galtseva, O.Y.Yakimchenko, Ya.S.Lebedev (Inst. of Chem. Phys., Moscow, USSR).
Chem. Phys. Lett. (Netherlands), vol.99, no.4, p.301-4 (12 Aug. 1983).
A linear magnetic field gradient superimposed on the main static field was used to study one-dimensional diffusion of perchlorotriphenylmethyl radicals in decalin and of oxygen molecules in polytetrafluoroethylene. A simple method is developed for deducing diffusion coefficents from both time-dependent and single-scan experiments provided that the natural linewidth is small relative to the field change over the diffusion distance. (13 refs.)

108776 High pressure anomaly of the spin lattice relaxation of the cerium ion in europium ethylsulphate. G.N.Neilo, A.D.Prokhorov.
Fiz. Nizk. Temp. (USSR), vol.9, no.8, p.877-9 (Aug. 1983). In Russian. English translation in: *Sov. J. Low Temp. Phys. (USA)*
Temperature dependences have been measured of the spin lattice relaxation rate for Ce^{3+} ion in europium ethylsulphate under high pressure. It has been found that with pressure increase an anomalous decrease of the relaxation rate takes place which proceeds as a jump with the temperature span 0.2K. (6 refs.)

108777 Temperature dependence of the spin Hamiltonian parameters in KCl:Eu^{2+} crystals. C.Pina, E.Munoz, J.L.Boldu (Inst. di Fisica, Univ. Nacional Autonoma de Mexico, Mexico City, Mexico).
J. Chem. Phys. (USA), vol.79, no.5, p.2172-6 (1 Sept. 1983).
The temperature dependence of the spin Hamiltonian parameters of Eu^{2+} in othorhombic sites of KCl crystals has been measured in the range 87-573K using EPR techniques. In this work, the authors fit an analytical expression for the predominant parameter $b_2{}^0$ as a function of temperature, $b_2{}^0=a_0+a_1T+a_2 \coth \Theta 2/T$. With eight experimental points the equation for $b_2{}^0$ was fitted and the following values were obtained $a_0=364.54\times10^{-4}$ cm^{-1}, $a_1=-0.03\times10^{-4}$ cm^{-1} K^{-1}, and $a_2=-5.72\times10^4$ cm^{-1}. The root of the mean squared deviation between calculated and reported values $\sigma=2.03\times10^{-4}$ cm^{-1}. (33 refs.)

108778 Dilemma of $EuMo_6X_8$ (X=S,Se) and possible solution of resistance anomaly [ESR study]. S.N.Ekbote, S.K.Gupta, A.v.Narlikar (Nat. Phys. Lab., New Delhi, India).
J. Phys. C (GB), vol.16, no.25, p.L919-23 (10 Sept. 1983).
Resistance behaviours of $Eu_{1.2}Mo_6X_8$ (X=S and Se) are analysed in terms of their ESR studies. The results show that while the interaction between condulation electrons and Eu^{2+} ions is negative in $Eu_{1.2}Mo_6S_8$, it is positive in $Eu_{1.2}Mo_6Se_8$. A comparative study of the spectra is obtained for Eu-doped $PbMo_6S_8$ samples, which again show that even for lower concentrations of Eu the interaction between conduction electrons and Eu^{2+} ions is negative. The data provide a plausible explanation to the resistance anomaly of $Eu_{1.2}Mo_6S_8$. (14 refs.)

108779 Effect of γ -irradiation on EPR spectra of Eu^{2+} doped KCl and NaCl crystals. H.Opyrchal, K.D.Nierzewski, H.Drulis (Inst. for Low Temperature & Structure Res., Polish Acad. of Sci., Wroclaw, Poland).
Phys. Status Solidi b (Germany), vol.118, no.2, p.K125-7 (1 Aug. 1983).
Ionising radiation affects the aggregation of Eu^{2+}-cation vacancy (I-V) dipoles in KCl and NaCl crystals to form some precipitates. Experiments were performed by measuring EPR spectra of KCl:Eu^{2+} and NaCl:Eu^{2+} crystals subjected, after previous annealing at 500°C during ≈ 1 h and quenching to room temperature, to γ-radiation at the dose rate $\approx 10^6$ R/h. The EPR spectra were compared with those obtained for crystals stored after the growth at RT for about five years. The measurements were performed in a conventional X-band reflection spectrometer. 108780 EPR study of the Tl^{2+} center in the paraelectric and antiferroelectric phases of $NH_4H_2PO_4$. D.N.Domingues, A.S.Chaves, G.M.Ribeiro, R.Gazzinelli (Dept. of Phys., Univ. Federal de Minas Gerais, Belo Horizonte, Brazil).
Solid State Commun. (USA), vol.47, no.9, p.665-8 (Sept. 1983).
The EPR Tl^{2+} center in $NH_4H_2PO_4$ was studied in the range of temperature 85K-175K which includes the antiferroelectric transition. The center has the symmetry of $NH_4{}^+$ site, where it goes substitutionally, in both the paraelectric and antiferroelectric phases. In the antiferroelectric phase there is a charge compensation mechanism involving the repulsion of one of the neighbour protons in the hydrogen bond. A measurement of the splitting of the resonance lines for the field along the crystallographic direction a is presented as a function of temperature. This splitting is proportional to the order parameter. (9 refs.)

108781 Paramagnetic centres in X-irradiated $LiNaSO_4$ single crystal: A comment. G.Lehmann (Inst. fur Phys. Chem., Univ. of Munster, Munster, Germany).
Cryst. Res. & Technol. (Germany), vol.18, no.7, p.K75-6 (1983).
For original paper see ibid., vol.16, p.611 (1981). The publication of Alybakov et al. contains several obvious errors in the presentation, evaluation and interpretation of their experimental results which the author comments on. He concludes that the proposed structures of these radiation defects in $LiNaSO_4$ appear to be correct despite the indicated errors. (4 refs.)

108782 Reply to comments on 'Paramagnetic centres in X-irradiated $LiNaSO_4$ single crystals'. A.A.Alybakov, V.M.Bujko, K.Sharsheev (Inst. of Phys. & Math., Acad. of Sci., Frunze, Kirghiz SSR).
Cryst. Res. & Technol. (Germany), vol.18, no.7, p.K77-8 (1983).
For original paper see ibid., vol.16, p.611 (1981). For comment see ibid., vol.18, p.K75 (1983). The authors reply to the comments of Lehmann on the paramagnetic centres in X-ray irradiated $LiNaSO_4$. They present additional experimental data which show that there is no error in the presentation of their experimental results. (7 refs.)

108783 Electron-spin-resonance studies of pyrrole polymers: Evidence for bipolarons. J.C.Scott, P.Pfluger, M.T.Krounbi, G.B.Street (IBM Res. Lab., San Jose, CA, USA).
Phys. Rev. B (USA), vol.28, no.4, p.2140-5 (15 Aug. 1983).
ESR measurements have been performed on samples of neutral polypyrrole, polypyrrole-perchlorate, oxygen-doped polypyrrole, and poly(β,β'-dimethylpyrrole perchlorate). A narrow Lorentzian line is observed in oxidized, highly conducting films, but no correlation between conductivity and either linewidth or intensity is found. Electrochemically cycled films, which remain highly conducting, show little or no detectable ESR absorption. It is deduced that the ESR signal seen in the as-prepared material does not arise from the current-carrying species, but rather from accidental neutral π-radical defects. The absence of paramagnetism in the metallic state is discussed within the framework of bipolaron formation. (13 refs.)

108784 Some features of surface formation during brittle failure of covalent crystals with diamond-type lattice according to EPR data. M.V.Vlasova, N.G.Kakazei (Inst. of Materials Sci., Acad. of Sci., Kiev, Ukrainian SSR).
Solid State Commun. (USA), vol.47, no.4, p.255-7 (July 1983).
The dependence was found of the intensity of 'mechanical paramagnetic centres' EPR signals on the temperature of grinding of diamond, silicon carbide, silicon and germanium crystals. Signals intensity increase with grinding temperature lowering (up to 77K) is related with formation of the materials' amorphous phase during their brittle failure as well as with specific features of the microcracks structure development. (20 refs.)

108785 A trapped-hole center causing rose coloration of natural quartz. D.Maschmeyer, G.Lehmann (Inst. fur Phys. Chemie, Westfalische Wilhelms-Univ., Munster, Germany).
Z. Kristallogr. (Germany), vol.163, no.3-4, p.181-96 (1983).
In rose-colored natural quartz crystals two new hole centers were detected and analyzed by electron paramagnetic resonance (EPR). A hole center with characteristic doublet and sextet hyperfine structures was identified as an O^- ion bridging between a substitutional aluminum and phosphorus atom each. This center slowly bleaches in UV light and can be enhanced by X-ray irradiation. It is most likely responsible for the rose coloration and also explains the repeatedly reported bleaching of 'rose' quartz in daylight. Light-induced transfer of the hole in the PO_4, not the AlO_4 unit is assumed to cause this strong visible absorption. All the phosphorus present is obviously associated with aluminum, in agreement with estimates of the equilibrium distribution based on a purely Coulomb attraction between Al^{3+} and P^{5+} on sites of Si^{4+}. The isotropic ^{27}Al superhyperfine structure is four times smaller than in the unperturbed smoky quartz center, evidently as a result of the strong electron attraction by the pentavalent phosphorus opposite to Al which also gives rise to a large and practically isotropic ^{31}P doublet superhyperfine splitting. 76.30R Free radicals

108786 Hydroxyl radicals in aqueous glasses: characterization and reactivity studied by ESR spectroscopy. H.Riederer, J.Huttermann (Inst. fur Biophys. und Phys. Biochem., Univ. Regensburg, Regensburg, Germany), P.Boon, M.C.R.Symons.
J. Magn. Resonance (USA), vol.54, no.1, p.54-66 (Aug. 1983).
The parallel g value (g_z) for hydroxyl radicals trapped in solids is goverened by the interaction with matrix molecules. In ice or salt hydrates this is primarily hydrogen bonding, which lifts the degeneracy of the $2p\pi$ orbitals in a precise manner yielding well defined g_z features in the electron spin resonance spectra. In contrast, when OH· radicals are formed in amorphous electrolyte glasses the g_z feature is extremely broad and detectable only as an ascending baseline. In the presence of small concentrations of organic substrate in the glasses, well defined products are formed from hydroxyl attack which occurs when they become mobile at elevated temperatures. This is in contrast with phase-separated aqueous systems and the results establish glasses like 7-9 *M* BeF_2/H_2O as suitable media for studying the reactions of hydroxyl radicals. (29 refs.)

108787 ESR studies of radicals derived from tetrahydrofuran derivatives. Share-Wing Ko, A.C.Ling (Dept. of Chem., San Jose State Univ., San Jose, CA, USA), R.J.Waltman, J.Bargon.
J. Magn. Resonance (USA), vol.54, no.1, p.67-77 (Aug. 1983).
Free radicals derived from tetrahydrofuran, 2,3- or 2,5-dihydrofuran as well as from some methoxy or mono- and di-methyl derivatives thereof have been generated via hydrogen abstraction via photolytically generated *t*-butoxy radicals. The g values of these radicals have been determined by ESR spectrometry and the hyperfine splitting constants have been assigned using deuterium labeling. Saturated systems give rise to cyclic alkyl radicals via hydrogen abstraction from the carbon in the α-position to oxygen; unsaturated systems yield cyclic allyl-type radicals. (25 refs.)

108788 Vanadyls from oil shale. Rotational motion studied by electron spin resonance spectroscopy. B.B.Garrett (Florida State Univ., Tallahassee, FL, USA), W.M.Gulick,Jr..
J. Chem. Soc. Faraday Trans. I (GB), vol.79, pt.8, p.1733-40 (Aug. 1983).
Electron spin resonance studies of several vanadyl complexes from the Antrim oil-shale formation of the lower Michigan peninsula reveal a wide range of rotational correlation times. The hyperfine splittings and g factors are all consistent with porphyrin structures, but three vanadyls have very different rotational correlation times. At ambient temperature, one gives a motionally averaged spectrum, one gives a slow-tumbling spectrum and one has its spectrum broadened into unobservability. A temperature-dependence study was carried out for the species which is in the slow tumbling region at ambient temperature. A rotational correlation time of 4.0×10^{-8} s rad^{-1} is estimated for this species at 303K and an activation energy of 6.9 kcal mol.$^{-1}$ is estimated for the rotation. (13 refs.)

76.40 DIAMAGNETIC AND CYCLOTRON RESONANCES

108789 Cyclotron resonance in the conduction band of GaP in very high magnetic fields. N.Miura, G.Kido, M.Suekane, S.Chikazumi (Inst. for Solid State Phys., Univ. of Tokyo, Tokyo, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2838-48 (Aug. 1983).
Cyclotron resonance in *n*-type GaP was observed in pulsed high magnetic fields up to 140 T using far-infrared lasers as radiation sources at 119 μm and 337 μm wavelengths. When the magnetic field was applied along the ⟨100⟩ axis, the second resonant peak was observed at 100 T in addition to the first peak at 23 T for a wavelength of 119 μm, the apparent anisotropy factor K^* of the effective mass on the assumption of an ellipsoidal band model being estimated to be 19 ± 2. For a wavelength of 337 μm, the second peak in the absorption was observed as a broad shoulder centered at 42 T, giving a different value of K^*. These observations were interpreted in terms of the camel's back structure model of the conduction band, and the band parameters were determined by a comparison of the data with calculation of the Landau levels.

108790 Theory of cyclotron resonance halfwidth for electrons scattered by impurities and phonons. T.K.Srinivas, S.Chaudhury, S.Fujita (Dept. of Phys. & Astron., State Univ. of New York, Amherst, NY, USA).
J. Phys. & Chem. Solids (GB), vol.44, no.9, p.931-7 (1983).
A general theory of the cyclotron resonance halfwidth for electrons scattered by impurities and phonons is developed on the basis of the proper connected diagram expansion of the current-correlation-function formula for the dynamic conductivity. The theory is applied to the cases of Ge samples at extremely high magnetic fields and different temperatures. The usual form of Matthiessen's rule $\Gamma=\Gamma_1+\Gamma_2+...$, where Γ and Γ_j are the total and component energy-dependent resonance widths, is valid only if the component widths Γ_j computed separately for each cause of scattering depend linearly on the densities of scatterers. The resonance width Γ_1 due to the charged impurities at very low electron densities ($\sim10^{12}$ cm^{-3}) and at very low temperatures is known to vary in proportion to the square-root of the impurity density. Large deviations from the Matthiessen's rule occur in such a case. The theory is in good quantitative agreement with currently available experimental data. In order to test the generalized form of Matthiessen's rule, however, the high-field resonance experiments around 15K is desirable where both phonon and impurity scatterings contribute in a comparable manner. (10 refs.)

Far-infrared magneto-plasma wave transmission and the dielectric constant in bismuth under high magnetic fields .... See Entry 108463

76.50 FERROMAGNETIC, ANTIFERROMAGNETIC, AND FERRIMAGNETIC RESONANCES; SPIN WAVE RESONANCE

(see also 75.30D Spin waves)

108791 Magnetic resonance in very fine ferrimagnetic powder. J.Kolacek (Inst. of Phys., Czechoslovak Acad. of Sci., Praha, Czechoslovakia).
Czech. J. Phys. Sect. B (Czechoslovakia), vol.B33, no.9, p.1024-34 (1983).
A simple model of a two-sublattice ferrimagnetic powder is described and numerically solved. In the framework of this model the ground state deviation from the exactly antiparallel spin order is estimated for very small particles and, by extrapolation, for the bulk material, too. This departure proved to be rather small. Besides usual ferrimagnetic resonance it is possible—according to the model—to expect three magnetic absorption lines—the exchange resonance and the two surface modes which are localized in the surface layer of the depth of about three lattice constants. The influence of the surface of the frequency and the intensity of the exchange resonance is also considered. (5 refs.)

108792 Influence of magnetostriction on FMR in thin garnet (111) films. L.Pust (Inst. of Phys., Czechoslovak Acad. of Sci., Prague, Czechoslovakia).
Phys. Status Solidi a (Germany), vol.78, no.2, p.741-9 (16 Aug. 1983).
Parallel and perpendicular resonance conditions are derived for films under stress σ applied either uniaxially along [110] or [112] directions, or isotropically in the film plane. The shift of the resonance field is expressed in a dimensionless form up to the fourth power of the magnetostriction constants λ_{100} and λ_{111} multiplied by σ, the influence of the cubic magnetocrystalline anisotropy is included. Only on the perpendicular configuration with isotropic σ the shift is a linear function of σ. A method for measuring λ_{100} on (111)-thin films is proposed. (5 refs.)

Mechanisms of magnetic losses in small-grain Ni-Zn ferrites .... See Entry 108730

76.60 NUCLEAR MAGNETIC RESONANCE AND RELAXATION

108793 High-resolution proton magnetic resonance and catalytic studies concerning Bronsted centers of amorphous Al_2O_3-SiO_2 solids. M.Hunger, D.Freude, H.Pfeifer (Sektion Phys., Karl-Marx-Univ. Leipzig, Leipzig, Germany), H.Bremer, M.Jank, K.-P.Wendlandt.
Chem. Phys. Lett. (Netherlands), vol.100, no.1, p.29-33 (26 Aug. 1983).
By application of the magic angle spinning (MAS) technique it was possible to observe highly resolved proton NMR spectra of the OH groups of amorphous silica-alumina. The spectra exhibit two lines at 2 and 7 ppm. The former line must be ascribed to non-acidic OH groups since it also occurs for silica and alumina. The latter line shows a maximum of intensity in the range of 20-30 wt.% Al_2O_3. It must be due to acidic hydroxyl groups since the catalytic activity of the silica-aluminas measured by the cracking rate of cumene shows quantitatively the same behaviour with respect to the number of OH groups at 7 ppm. (15 refs.)

108794 Cadmium-113 shielding tensors of cadmium-oxo compounds. I. Single-crystal studies on $Cd(NO_3)_2.4H_2O$ and $3CdSO_4.8H_2O$. R.S.Honkonen, F.D.Doty, P.D.Ellis (Dept. of Chem., Univ. of South Carolina, Columbia, SC, USA).
J. Am. Chem. Soc. (USA), vol.105, no.13, p.4163-8 (29 June 1983).
Diffraction-quality single crystals of $Cd(NO_3)_2.4H_2O$ and $3CdSO_4.8H_2O$ have been investigated by ^{113}Cd Fourier transform NMR methods in a home-built single-crystal probe. As expected from point group symmetry arguments, the shielding tensors do not exhibit axial symmetry. The ^{113}Cd NMR of $Cd(NO_3)_2.4H_2O$ gave rise to two cadmium resonances for the magnetically nonequivalent (but crystallographically equivalent) positions in the unit cell. The principal elements of the symmetry related tensors for $Cd(NO_3)_2.4H_2O$ are -174.4, -154.3, and 22.2 ppm for σ_{11}, σ_{22}, and σ_{33}, respectively (the chemical shifts are reported with respect to solid $Cd(ClO_4)_2$). The ^{113}Cd NMR of $3CdSO_4.8H_2O$ afforded three resonances as expected from the crystal symmetry. Two of the resonances are assigned to general positions within the lattice. These positions gave rise to symmetry-related tensors, which have principal elements -93.1, -76.7, and 25.5 ppm. The remaining resonance is assigned to cadmium in special position; the corresponding shielding tensor has principal elements -95.6, -85.3, and -3.4 ppm. These data are discussed in terms of the structure of the cadmium salts. (24 refs.)

108795 Fourth moment of the magnetic resonance line of a dipolar coupled rigid lattice for powders with two different species of magnetic nuclei. B.Nowak, J.Kowalewski, O.J.Zogal (Inst. for Low Temperature & Structure Res., Polish Acad. of Sci., Wroclaw, Poland).
J. Magn. Resonance (USA), vol.54, no.1, p.9-18 (Aug. 1983).
A general analytical expression for calculating the polycrystalline fourth moment of a nuclear magnetic resonance line is given for powders with two different species of magnetic nuclei. Only Cartesian coordinates of the magnetic nuclei are necessary as input data in numerical calculation of M_4 for cubic, tetragonal and orthorhombic crystals. Numerical values of appropriate lattice sums are given for powders of crystals having CaF_2 and NaCl structures. (9 refs.)

108796 Carbon-13 chemical shielding tensors in L-threonine. N.Janes, S.Ganapathy, E.Oldfield (School of Chem. Sci., Univ. of Illinois, Urbana, IL, USA).
J. Magn. Resonance (USA), vol.54, no.1, p.111-21 (Aug. 1983).
The carbon-13 chemical shielding tensors of the amino acid L-threonine have been determined by solid state proton-enhanced NMR of a single crystal at 3.52 T. For the first time a carbinol shielding tensor is determined quantitatively and unambiguously; the most shielded axis lies 4° from the C-O bond.

A coordinate system which approximates the alpha carbon tensor orientation is proposed, and it is suggested that this 'local symmetry' may be general to many amino acid alpha carbons. The carboxyl and methyl tensor orientations closely approximate previously established 'local symmetry', although the methyl (C^{γ}) C_{3v} symmetry is slightly disrupted, apparently by the neighboring (O^{γ}) oxygen. The influence of the carbon-nitrogen dipolar interaction on the observed spectra is discussed, and used to make unique assignments for the carboxyl, alpha, and beta carbon tensors. (36 refs.)

108797 Multipulse 'spin-locking' effect on a dipolar ordered state. L.Quiroga, J.Virlet (Dept. de Phys.-Chimie, CENS, Gif-sur-Yvette, France), M.Goldman.
J. Magn. Resonance (USA), vol.54, no.1, p.161-4 (Aug. 1983).
Recently it was shown how the heat capacity of the dipolar energy reservoir could be varied adiabatically by the slow switching on of some line-narrowing multipulse sequences of the WHH-4 type. Adiabaticity and reversibility of such a process breaks down, however, when the value of the pulse angle θ approaches 90° because the dipolar interaction strength is then so low that spin diffusion takes a prohibitively long time. For the same reason, a spin temperature cannot be established in the toggling frame when such a multipulse sequence is turned on suddenly at $\theta \approx 90°$. The authors present a particular situation where these difficulties are absent, i.e. a pulse sequence for which the magnitude of the effective dipolar interaction is modified, but not its form. If the system is initially at equilibrium with respect to these interactions its state will be unaffected by the switching on or off of this pulse sequence, whose only effect is a sudden but isentropic scaling of the dipolar reservoir heat capacity (and spin temperature). The authors have performed an experiment on a polycrystalline sample of adamantane. (6 refs.)

108798 Deuterium NMR of molecules adsorbed on active alumina. H.E.Gottlieb, Z.Luz (Weizmann Inst. of Sci., Rehovot, Israel).
J. Magn. Resonance (USA), vol.54, no.2, p.257-71 (Sept. 1983).
Deuterium NMR spectra were recorded of a number of perdeuterated compounds adsorbed on active alumina. The compounds include benzene, *p*-xylene, pyridine, acetone, acetonitrile, cyclohexane, methanol, and water and were studied in the range probe/alumina=0.02 to 0.30 (w/w). In most cases the spectra were typical of powder samples exhibiting a finite quadrupole interaction tensor. The quadrupole parameters depend on the probe/alumina ratio and on the temperature. The results are interpreted in terms of a model in which each crystallite surface supports an ordered layer of molecules which are in fast dynamic equilibrium with disordered 'bulk' molecules associated with the same surface. In the case of benzene the average quadrupole tensor was biaxial and in the case of acetone the spectrum appears to be a superposition of spectra from two distinct sites. The results demonstrate that deuterium NMR may provide a useful tool for the study of molecular ordering and molecular motion of adsorbed probes and may become an important complementary technique for the study of interface systems in general. (11 refs.)

108799 Methyl rotation in 1,2,4,5-tetramethylbenzene and tetramethylpyrazine in the solid state. Tunneling spectra by proton NMR. S.Takeda, H.Chihara (Dept. of Chem., Osaka Univ., Osaka, Japan).
J. Magn. Resonance (USA), vol.54, no.2, p.285-99 (Sept. 1983).
The temperature dependence of proton spin-lattice relaxation behaviour in 1,2,4,5-tetramethylbenzene (durene) and tetramethylpyrazine (TMP) was measured with particular attention to the dependence of magnetization recovery on the kind of pulse sequences. The tunneling spectra of the methyl groups of durene and TMP, which correspond to the tunneling-assisted maxima of the spin-lattice relaxation rate, were obtained by the NMR field-cycling method. The three tunneling splittings were observed for both materials in the low temperature limit: 29.3±0.7 MHz, 25.3±0.6 MHz, and 17.8±0.5 MHz for durene and 26.8±0.8 MHz, 20.2±0.8 MHz, and 14.3±0.6 MHz (or 6.4±0.7 MHz) for TMP. Those tunneling spectra indicate collective rotational tunneling of the two neighboring methyl groups in the molecules. There is an indication that the apparent tunneling frequencies decrease as the temperature increases. The effects of correlated reorientation of two methyl groups on the spin-lattice relaxation rate are discussed. (45 refs.)

108800 Quadrupolar ordering in a non-magnetic cubic doublet system: Cs_2NaHoF_6. E.J.Veenendaal, H.B.Brom, W.J.Huiskamp (Kamerlingh Onnes Lab., Rijksuniv. Leiden, Leiden, Netherlands).
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.1-29 (1983).
The cubic elpasolite Cs_2NaHoF_6 is a van Vleck-paramagnet with a non-magnetic Γ_3-doublet ground state and an enhanced nuclear magnetic moment. The degeneracy of the ground state is lifted at a phase-transition temperature $T_c = 393 \pm 5$ mK, as determined from specific heat measurements. Calculations indicate, that the quadrupolar interactions, which drive the phase transition, mainly arise from the electron-lattice interaction. The transition may thus be regarded as a cooperative Jahn-Teller effect. The enhanced nuclear magnetic resonance spectrum of ^{165}Ho ($I=7/2$) has been measured at lattice temperatures from 4.2K down to 20 mK. The enhanced nuclear gyromagnetic ratio along a [001]-axis rises from 1.16 GHz/T at 4.2K to 2.33 GHz/T at 20 mK. The last value corresponds to an enhancement factor $K=258$. The NMR-spectra indicate that the low-temperature phase is ferro-quadrupolar in a magnetic field of 0.1 T. In nuclear demagnetization experiments a nuclear spin temperature of 1.8 mK has been obtained. The NMR-spectra do not indicate nuclear magnetic order. (44 refs.)

108801 Nuclear acoustic resonance in single-crystal gold metal. R.K.Sundfors (Dept. of Phys., Washington Univ., St. Louis, MO, USA).
Phys. Rev. B (USA), vol.28, no.4, p.2284-6 (15 Aug. 1983).
Nuclear acoustic resonance is reported for the first time for ^{197}Au in single-crystal gold metal. The ratio $\omega^{(197)}/H$ was measured to be $(2\pi)(74.118 \pm 0.007)$ Hz/G and the line shape of the $\Delta m = \pm 2$ resonance was a Lorentz line shape with a half width at half amplitude of 154.8±1 G at 78K after high-temperature annealing. S tensor components which relate dynamic electric field gradients with dynamic elastic strain are determined to be of opposite sign and their magnitudes are $S_{11}\text{-}S_{12} = 13.6 \times 10^{15}$ statvolts/cm^2 and $S_{44} = 13.0 \times 10^{15}$ statvolts/cm^2. Lattice contributions to these components are computed and the conduction-electron contributions determined. (12 refs.)

76.60C Chemical and Knight shifts

108802 High-field static and MAS ^{31}P NMR: chemical shift tensors of polycrystalline potassium phosphates $P_2O_5.xK_2O$ $(0 \leq x \leq 3)$. A.-R.Grimmer (Central Inst. of Inorganic Chem. Acad. of Sci., Berlin, Germany), U.Haubenreisser.
Chem. Phys. Lett. (Netherlands), vol.99, no.5-6, p.487-90 (19 Aug. 1983).
Static and MAS ^{31}P NMR spectra of polycrystalline h-P_4O_{10} and phosphates K_3PO_4, $K_4P_2O_7$, $K_5P_3O_{10}$, $K_3P_3O_9$ and $(KPO_3)_x$ were measured at 109.3 MHz. It is shown that the principal values of the ^{31}P shielding tensor and the isotropic ^{31}P chemical shift values reflect sensitively the constitution of both the various phosphate anions and the phosphorus oxide h-P_4O_{10}. (17 refs.)

108803 Effects of restricted molecular motion on the high-resolution solid-state ^{13}C CP MAS NMR spectrum of the nitrile group of the stearonitrile-urea inclusion complex. M.Okazaki, A.Naito, C.A.McDowell (Dept. of Chem., Univ. of British Columbia, Vancouver, British Columbia, Canada).
Chem. Phys. Lett. (Netherlands), vol.100, no.1, p.15-18 (26 Aug. 1983).
The solid-state ^{13}C CP MAS NMR spectra of stearonitrile and its urea inclusion complex were observed at room temperature. The splitting of the nitrile group in the complex was 92 Hz, and was 330 Hz for crystalline stearonitrile. This reduction can be explained by the assumption that the included molecule rotates rapidly ($\tau_R < 10^{-8}$ s) around the c axis of the complex. (12 refs.)

108804 ^{19}F NMR spectra of hexafluoride groups: UF_6. E.P.Zeer, O.C.Falaleev, V.E.Zobov (L.V. Kirensky Inst. of Phys., SB AS, Krasnoyarsk, USSR).
Chem. Phys. Lett. (Netherlands), vol.100, no.1, p.24-8 (26 Aug. 1983).
Using the example of the ^{19}F NMR spectrum of polycrystalline UF_6 in a magnetic field of 5 T, the authors propose a new interpretation of NMR spectra of hexafluoride groups in solids. A simple theoretical model explains the contradiction with the earlier interpretation and corrects the NMR conclusion on the symmetry of the UF_6 molecule. (13 refs.)

108805 Temperature dependence of Knight shift in Cd-Mg alloys. S.A.Vorontsov, G.E.Grechnev.
Fiz. Nizk. Temp. (USSR), vol.9, no.8, p.884-7 (Aug. 1983). In Russian. English translation in: *Sov. J. Low Temp. Phys. (USA)*
The contribution to the isotropic part of the Knight shift in cadmium from the states on the narrow neck of the hole surface of the second zone (monster) is calculated. Because of E_F proximity to the point where the Fermi surface topology changes, the behavior of K_{iso} with rising temperature and magnesium impurity addition is mainly governed by the electron spectrum rearrangement due to the effects of the Debye-Waller factor, the impurity potential and the lattice parameter variations. The calculated dependences of K_{iso} on temperature and concentration in $Cd_{100-x}Mg_x$ alloys are consistent with experimental results. (10 refs.)

108806 Dispersed liquid phase referencing of NMR spectra. J.Homer (Dept. of Chem., Univ. of Aston, Birmingham, England).
J. Magn. Resonance (USA), vol.54, no.1, p.1-8 (Aug. 1983).
It is shown that suitable liquids, when dispersed through samples with which they are immiscible, can be used as otherwise uncontained references for the measurement of chemical shifts. These shifts are independent of the volume magnetic susceptibility of the components of the heterogeneous sample. The ^1H chemical shifts for various compounds in model systems have been measured using both the traditional external reference and the new dispersed methods and the differences between these are explained. (13 refs.)

108807 NMR chemical shifts of ^{51}V, ^{93}Nb, ^{181}Ta, and ^{205}Tl in ternary A_3BC_4 semiconductors. K.D.Becker, U.Berlage (Inst. fur Phys. Chem. & Elektrochem., Univ. Hannover, Hannover, Germany).
J. Magn. Resonance (USA), vol.54, no.2, p.272-84 (Sept. 1983).
Chemical shifts of the group-V transition metals, V, Nb, and Ta, and of Tl(I), were determined in 15 ternary semiconductors of the cubic A_3BC_4 sulvanite type. The transition metal ions were found to possess large shielding ranges of approximately 2000 ppm for Nb and 3000 ppm for V and Ta, while the thallium shifts span a range of 800 ppm. For a given cation, shifts increase with increasing atomic number of the chalcogen. These data were compared with predictions of a localized-bond model using Harrison's bond-orbital model (1980). Good agreement is obtained between the observed shifts and calculated values for the paramagnetic contribution to chemical shielding. (29 refs.)

108808 A linear relationship between the ^{13}C ester carbon chemical shift and the melting point or S to N transition temperature of n-alkyl esters of biphenyl-4,4′-dicarboxylic acid. J.K.Swadesh, J.C.Poirier (Dept. of Chem., Duke Univ., Durham, NC, USA).
Mol. Cryst. & Liq. Cryst. Lett. (GB), vol.92, no.4-5, p.119-26 (1983).
The authors present evidence that the relative electron densities at the ester carbon of the symmetrical n-alkyl diesters of biphenyl-4,4′dicarboxylic acid may determine the relative melting points of homologs in this series. A similar relationship may determine the relative smectic to nematic transition temperatures of the corresponding monoesters. They present a model to rationalize their observations. (12 refs.)

108809 Magnetic couplings in Cs_2IrCl_6 and other iridium hexachlorides from NMR studies. A.M.Raaen, I.Svare (Phys. Dept., Univ. of Trondheim, Trondheim, Norway), B.Pedersen.
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.88-94 (1983).
NMR line shift and relaxation of ^{133}Cs in FCC Cs_2IrCl_6 show that this salt is antiferromagnetic with $T_N < 1.6$K and $\theta = -4 \pm 2$K. The contact couplings $A\mathbf{I}_i.\mathbf{S}_j$ of ^{133}Cs to Ir^{4+} are much larger than the corresponding dipolar couplings, $A_1/h = -5.9$ MHz to nearest neighbours and $A_2/h = 0.9$ MHz to the next nearest neighbours. The corresponding couplings to ^{39}K in K_2IrCl_6 are $A_1/h = -0.3$ MHz and $A_2/h = 0.05$ MHz. The Ir^{4+}-Ir^{4+} superexchange $J_1\mathbf{S}_j.\mathbf{S}_k$ vary very rapidly with alkali ion A^+ substitution in the iridium hexachlorides. The authors suggest that this is due to an increasing ferromagnetic coupling $IrCl_6^{2-}(\uparrow)$-$A^+(\downarrow)$-$Cl_6Ir^{2-}(\uparrow)$ partly counteracting the decreasing antiferromagnetic coupling $IrCl_6^{2-}(\uparrow)$-$Cl_6Ir^{2-}(\downarrow)$ when one goes from $A^+ = K^+$, NH_4^+ and Rb^+ to $A^+ = Cs^+$. They give some very crude estimates for the strengths of the superexchanges. (27 refs.)

108810 Knight shift of H adatoms on $Cu_{1-x}Ni_x$ alloy. S.Modak, B.C.Khanra (Solid State & Molecular Phys. Div., Saha Inst. of Nuclear Phys., Calcutta, India).
Phys. Rev. B (USA), vol.28, no.4, p.2279-980 (15 Aug. 1983).
A simple model in terms of chemisorption-induced segregation has been proposed to explain the observed Ni concentration dependence of the Knight shift of a hydrogen atom chemisorbed on $Cu_{1-x}Ni_x$ alloy systems. It has been suggested that the adatom Knight-shift measurement may be a new way to probe the chemisorption-induced segregation in alloys and adatom coverages on surfaces. (15 refs.)

76.60E Relaxation effects

108811 Motional behavior of 2,3:5,6-di-O-isopropylidene-α-D-mannofuranose in solution. A ^{13}C spin-lattice relaxation study. P.Dais, A.S.Perlin (Dept. of Chem., McGill Univ., Montreal, Quebec, Canada).
Can. J. Chem. (Canada), vol.61, no.7, p.1542-8 (July 1983).
^{13}C nuclear magnetic resonance spin-lattice relaxation times (T_1) have been used to probe the motional behavior of 2,3:5,6-di-*O*-isopropylidene-α-D-mannofuranose in dimethyl sulfoxide solution. This system offers structural features well suited to the study of a variety of internal motions, i.e. ring oscillation, ring puckering interconversion and methyl internal rotation, all of which are superimposed on an isotropic overall reorientation. Among various models examined to evaluate internal rotations, a two-sites jump model was found satisfactory for interpreting the oscillation and puckering motions of the flexible 5,6-*O*-isopropylidene ring, whereas a diffusional model described hindered rotation of the geminal methyl groups of the rigid 2,3-*O*-isopropylidene ring from 15° to 80°C. (25 refs.)

108812 Formulae for intramolecular nuclear magnetic relaxation in an anisotropic medium. D.Canet, J.Brondeau (Lab. de Methodologie, Univ. de Nancy I, Vandoeuvre-les-Nancy, France).
Chem. Phys. Lett. (Netherlands), vol.100, no.1, p.70-5 (26 Aug. 1983).
Woessner's formulae have been adapted to the anisotropic medium case. The molecular vector involved in nuclear magnetic relaxation is assumed to rotate around an axis Δ which reorients itself within a phase possessing a preferred direction. General formulae concerning the spectral densities $J_0(\omega)$, $J_1(\omega)$ and $J_2(\omega)$ are established. The special situation for which the director is at the magic angle with the magnetic field is discussed and compared with the isotropic case. (15 refs.)

108813 Influence of spin-spin interactions on the nuclear spin-lattice relaxation in magnetically ordered substances. L.L.Buishvili, S.V.Ivanov, A.V.Kunevich, M.I.Kurkin (Inst. of Phys., Acad. of Sci., Tbilisi, Georgian SSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.94-103 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The longitudinal $1/T_1$ and transverse $1/T_2$ rates of relaxation of the ^{57}Fe nuclear spins in lithium ferrite depended similarly on the temperature of a sample and concentrations of some impurities. This similarity was explained on the assumption that the values of $1/T_1$ and $1/T_2$ were governed by the indirect (via magnons) interactions of nuclear spins with one another and with rapidly relaxing magnetic moments of the impurity atoms. A preliminary estimate was obtained of the necessary concentration of such impurities. It was found to be fairly low (less than 10^{-4} at.%), so that it would be difficult to monitor by direct methods. One of the mechanisms of the influence of the indirect interaction via magnons on $1/T_1$ corresponding to spin diffusion was investigated in detail. This mechanism failed to account for the observed correlation between the relaxation rates $1/T_1$ and $1/T_2$. (21 refs.) *A.T.*

108814 Proton spin-lattice relaxation in the three metamagnetic states of $CoCl_2.2H_2O$. T.Goto (Dept. of Phys., Kyoto Univ., Kyoto, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2514-22 (July 1983).
The field-, temperature- and angular dependences of T_1 of proton in the three metamagnetic states of Ising-like one-dimensional antiferromagnet $CoCl_2.2H_2O$ have been studied in view of two different types of relaxation mechanisms; the two-magnon process and the relaxation process due to scattering between one-magnon excitation and two-magnon bound state. The calculations for the former process based on the small-k approximation are in good agreement with the experimental results in the antiferromagnetic state with the external fields less than about 23 kOe. The experimental results in higher fields (223 kOe) over the three metamagnetic states are reasonably interpreted by the latter process, which predicts an approximate equation $T_1^{-1} \sim \exp(-2g_{||}\mu_B H_{eff}/k_B T)$ where H_{eff} is an effective field acting on effective ferromagnetic chains in each of the three states.

108815 NMR study of $GdRh_4B_4$ and $SmRh_4B_4$. Y.Kohori (Dept. of Phys., Kobe Univ., Kobe, Japan), K.Kumagai, K.Asayama.
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2910-17 (Aug. 1983).
Pulses NMR study of ^{11}B has been performed in $GdRh_4B_4$ and $SmRh_4B_4$ at frequencies of 1-10 MHz and at 50 mK-300K. From the isotropic Knight shitf, the authors obtained the conduction electron spin polarization at B site. T_1 in the paramagnetic state is explained by the dipolar and RKKY coupling between ^{11}B and the rare earth (RE) moments which are modulated by the RE-RE exchange interaction and the s-f interaction. Below the magnetic transition temperature both the line width and T_1 increase, which is associated with the magnetic ordering. In $SmRh_4B_4$ NMR measurement was made in the antiferromagnetic and superconducting states. Appreciable difference in T_1 was not observed between the normal and superconducting state. (13 refs.)

108816 ^{133}Cs spin-lattice relaxation in pseudo-one-dimensional CsH_2PO_4. R.Blinc, B.Lozar, B.Topic, S.Zumer (Dept. of Phys., E. Kardelj Univ. of Ljubljana, Ljubljana, Yugoslavia).
J. Phys. C (GB), vol.16, no.25, p.5053-62 (10 Sept. 1983).
The ^{133}Cs spin-lattice relaxation rate T_1^{-1} has been determined in the paraelectric phase of CsH_2PO_4. The anomalously short values of T_1 as well as the form of the critical temperature dependence are the result of the pseudo-one-dimensional nature of the fluctuations in this O-H$-$O bonded order-disorder system. The time between two successive passages of domain walls separating oppositely polarised one-dimensional short-range ordered clusters through a given ^{133}Cs site is short compared with 10^{-5}s in the whole paraelectric temperature range investigated. (20 refs.)

108817 A study of the low spin$\rightleftharpoons$high spin transitions in $[Fe(phen)_2(NCSe)_2]$, $[Fe(bipy)_2(NCS)_2]$, and $[Fe(isoxazole)_6](ClO_4)_2$ complexes using ^1H nuclear magnetic resonance. B.Maiti, B.R.McGarvey, P.Sambasiva Rao, L.C.Stubbs (Dept. of Chem., Univ. of Windsor, Windsor, Ontario, Canada).
J. Magn. Resonance (USA), vol.54, no.1, p.99-110 (Aug. 1983).
The spin-crossover complexes $[Fe(phen)_2(NCSe)_2]$ (phen=1,10 phenanthroline), $[Fe(bipy)_2(NCS)_2]$ (bipy=2-2′bipyridyl), and $[Fe(isoxazole)_6](ClO_4)_2$ have been studied using proton NMR. The spin-lattice relaxation times T_1 and the linewidths have been measured above and below the transition temperature. The transition from the low spin state to the high state is accompanied by a marked increase in the linewidth and a sharp decrease in the value of T_1, and vice versa. In the paramagnetic region T_1 remains constant (approximately 3 msec), whereas the linewidth varies as the inverse of the temperature T. For $[Fe(isoxazole)_6](ClO_4)_2$, a pronounced separate peak on the low frequency side of the spectrum is assigned to the hydrogen ortho to the nitrogen in the isoxazole ring. The lineshape analysis using a point-dipole model gives a value of 331 pm for the Fe-H distance. The results of the T_1 measurements support the Ising-type theory of these transitions and appropriate thermodynamic parameters for the transitions were determined by fitting the $\ln T_1$ vs. T^{-1} plot to the theory. To achieve a good fit it was found necessary to assume a temperature dependence for the correlation time below the transition temperature. (19 refs.)

108818 Frequency dependence of the effects of eccentricity on nuclear magnetic relaxation in liquids. ^{13}C relaxation of neopentane due to free radicals. P.H.Fries (Dept. de Recherche Fondamentale, CENG, Grenoble, France), J.P.Albrand, M.C.Taieb, E.Belorizky, M.Minier.
J. Magn. Resonance (USA), vol.54, no.2, p.177-89 (Sept. 1983).
Measurements of the relaxation time T_1 of the central and of the four equivalent off-center ^{13}C nuclei in neopentane, $C(CH_3)_4$, were performed in solutions containing di-tert-butyl nitroxide free radicals. In such systems, the intermolecular dipole magnetic interaction with the electronic spins of the free radicals is the only efficient relaxation mechanism for the resonating ^{13}C nuclei. The difference between the relaxation times of the central and of the off-center carbons was measured at three different resonance frequencies (15, 25, and 63 MHz) at $T=303K$. Spin exchange has a negligible effect and the results are interpreted using the spectral densities resulting from the molecular translational and rotational motions as the authors estabished previously. The effects of eccentricity cannot be explained with a uniform equilibrium distribution of the interacting molecules. It is essential to take into account pair correlation effects and the translational diffusive motion of the molecules must be described by a Smoluchowski equation. Good agreement with experiment is then obtained for the relaxation times and the effects of eccentricity. (31 refs.)

108819 Spin-lattice relaxation of ^{13}C in solid amino acids using the CP-MAS technique. A.Naito, S.Ganapathy, K.Akasaka, C.A.McDowell (Dept. of Chem., Univ. of British Columbia, Vancouver, British Columbia, Canada).
J. Magn. Resonance (USA), vol.54, no.2, p.226-35 (Sept. 1983).
It is shown by a simple application of relaxation theory that the ^{13}C magnetization decays nonexponentially, in principle, in the CP-MAS experiment because of the distribution of the spin-lattice relaxation times; however, the deviation from the exponential decay is quite small. The transient Overhauser effect also contributes appreciably to the nonexponential decay of the ^{13}C magnetization when the protons are not saturated during the ^{13}C T_1 measurements and the correlation time of the group rotational motion satisfies the condition, $\omega^2\tau_c^2 \leq 1$. It is shown by both experiment and theory that the transient Overhauser effect in the solid state is much smaller than that expected for the liquid state. The ^{13}C spin-lattice relaxation times of L-alanine, deutero-L-alanine, glycine, and L-serine were determined for the individual carbon atoms. The experimentally obtained ^{13}C T_1 values agree well with calculated ones, showing that the CH_3 group rotation provides the main source of the relaxation in alanine, while the NH_3^+ group motion plays an important role for the relaxation in glycine and serine. (21 refs.)

108820 Sulfur-33 spin-lattice relaxation time in the sulfate anion: concentration and temperature effects. J.F.Hinton, D.Shungu (Dept. of Chem., Univ. of Arkansas, Fayetteville, AR, USA).
J. Magn. Resonance (USA), vol.54, no.2, p.309-11 (Sept. 1983).
The authors report the results of an investigation of the ^{33}S spin-lattice relaxation time (T_1) of $^{33}SO_4^{2-}$ anion as a function of concentration and temperature. The T_1 value for the ^{35}Cl and ^{37}Cl in the ClO_4^- anion was also measured. A comparison is made between the T_1 for the $^{33}SO_4^{2-}$ anion and that of the $^{35}ClO_4^-$ and $^{37}ClO_4^-$ to determine the effect of quadrupole moment magnitude and anion charge on the ^{33}S relaxation. Although the relative receptivity of the ^{33}S nucleus is low, very good signal-to-noise spectra can be obtained with the $^{33}SO_4^{2-}$ anion which makes it possible to perform accurate T_1 experiments using the inversion recovery technique. For a 1 *M* $(NH_4)_2SO_4$ solution, a signal-to-noise ratio of approximately 10 to 1 was obtained from the Fourier transform of 500 accumulated free induction decays using a line-broadening factor of 0.5 Hz. A spectral width of 400 Hz stored in 2K memory was used for all spectra. For each T_1 experiment 15 to 20 tau values were used and 4000 to 6000 free-induction decays accumulated for each tau value. The average of a minimum of three measurements was used as the representative value for each concentration and temperature. (16 refs.)

108821 On nuclear magnetic relaxation due to slow molecular reorientation and fast internal rotation interference. Lian-Pin Hwang (Dept. of Chem., Nat. Taiwan Univ., Taipei, Taiwan).
Mol. Phys. (GB), vol.49, no.6, p.1341-52 (20 Aug. 1983).
Spin-lattice relaxation arising from modulation of the dipole-dipole interaction by slow molecular motion together with fast internal rotation interference is investigated. The magnetic interaction for the internal rotation is treated as a perturbation and a modified stochastic Liouville equation, which is exact in all orders of the residual perturbation for the overall reorientation of the molecule, is derived after averaging over the internal rotation modes. The resultant equation is solved by the eigenfunction expansion method to study the spin-lattice relaxation. Results show complicated damping oscillations which Donskaya's work (1975) has failed to predict. Such oscillations in the relaxation are found in the slow motion region. Effects due to jump diffusion and brownian diffusion in the internal rotation are also considered. (11 refs.)

108822 Entangled linear polymer chains in melts: n.m.r. and Rouse or reptation models; stress relaxation. J.P.Cohen-Addad (Lab de Spectrometrie Phys., Univ. Sci. et Medicale de Grenoble, Saint-Martin d'Heres, France).
Polymer (GB), vol.24, no.9, p.1128-38 (Sept. 1983).
Deals with detailed descriptions proposed to analyse slow chain diffusional process effects on n.m.r. properties of nuclei linked to long linear polymer molecules in melts or in concentrated solutions. It aims to predict relationships among macroscopic viscoelastic properties and semi-local dynamical properties observed from n.m.r. These relationships are discussed considering two main models of low-frequency chain fluctuations in melts; a multiple relaxation-mode spectrum analogous to a Rouse model or a single relaxation-mode spectrum analogous to a reptation model. The Rouse model was chosen because n.m.r. properties might be sensitive to the equilibration process of conformational fluctuations within a so-called 'tube' as well as to the reptation in a 'tube'. Local molecular properties are transferred to the unusual n.m.r. semi-local space scale (<30 Å) through the submolecule concept: every monomeric unit is supposed to have a uniform average orientational order within a given submolecule. Semi-local dynamical properties are analysed from the transition of the spin-system response from a pseudo-solid behaviour to a liquid-like one, induced by shortening polymer molecules or by slightly diluting them. This transition is currently observed from the transverse magnetic relaxation function of nuclei linked to entangled polymer chains. This spin-system response is contrasted to the longitudinal response only sensitive to local high relaxation frequency motions. Stress-relaxation processes induced on a macroscopic scale can be monitored on a semi-local space scale from n.m.r. Relaxation rates of the transverse magnetization depend strongly upon both the initial stretching ratio λ of the polymer sample and the structure of its chain relaxation spectrum. (29 refs.)

108823 On the intramolecular spin-lattice relaxation in reorienting three-spin $^1/_2$ systems. S.Emid, J.Smidt (Lab. voor Tech. Natuurkunde, Tech. Hogeschool Delft, Delft, Netherlands).
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.47-52 (1983).
For three-spin $^1/_2$ systems like CF_3 groups reorienting about their C_3-axes which make an angle β with the magnetic field, theory predicts that under extreme narrowing condition the ratio of the intramolecular dipolar and Zeeman relaxation times $(T_{1D}/T_{1Z})_{\mathrm{intra}}=(2/3)(1+3\cos^2\beta)$. Experiments on a CF_3COOAg single crystal confirm this. Even with intermolecular contributions included their ratio is found to be greater than $^1/_2$, whereas for most dipolar solids it is $\leq ^1/_2$. (10 refs.)

108824 Critical indirect nuclear coupling in Rb_2IrCl_6. A.M.Raaen, I.Svare (Phys. Dept., Univ. of Trondheim, Trondheim, Norway).
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.95-9 (1983).
The observed critical ^{87}Rb NMR line broadening $T_2=T_1/10\propto(T-T_N)^{0.33}$ in paramagnetic and FCC Rb_2IrCl_6 is caused by critical indirect nuclear coupling via the correlated Ir^{4+} electron spins. The theoretical critical index for T_2 is shown to be 0.33 for both static and rapidly relaxing nuclear neighbours, using scaling theory and the accepted values for the 3D Heisenberg critical exponents. The simpler mean field approximation with the known contact couplings in Rb_2IrCl_6 gives the correct order of magnitude for T_2 if it is assumed that the antiferromagnetic mode is of type 2. (15 refs.)

108825 ^{29}Si nuclear magnetic resonance and relaxation in the paramagnetic state of $CeCu_2Si_2$. J.Aarts, F.R.de Boer (Natuurkundig Lab., Univ. van Amsterdam, Amsterdam, Netherlands), D.E.MacLaughlin.
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.162-8 (1983).
^{29}Si nuclear magnetic resonance (NMR) and relaxation studies of the unstable-moment compound $CeCu_2Si_2$ have been carried out to probe the electronic state of the nearly-trivalent Ce ions. Isotropic and anisotropic NMR shifts indicate effects of both crystalline electric fields (CEF) and low-temperature moment reduction on the Ce ionic states. A relatively large anisotropic shift was observed at low temperatures, and also obtained from a CEF-state calculation in the molecular-field approximation. The hyperfine coupling also appears to be anisotropic, although this is not manifested in the temperature dependence of the shift due to changing CEF-state populations. NMR estimates of the Ce-spin fluctuation time vary with temperature in a manner similar to the neutron quasielastic scattering linewidth at high temperatures, but suggest the onset of spatially coherent fluctuations. (15 refs.)

108826 Composition and temperature dependence of the density of states at the Fermi level in vanadium-based A-15 compound systems [NMR study]. A.Gevers, T.O.Klaassen, N.J.Poulis (Kamerlingh Onnes Lab., Rijksuniv. Leiden, Leiden, Netherlands), H.R.Khan, C.J.Raub.
Physica B & C (Netherlands), vol.122B+C, no.1, p.55-66 (Sept. 1983).
The nuclear spin-lattice relaxation time T_1 of the V, Pt and Ga nuclei in the A-15 systems $V_{1-x}Pt_x$, $V_{1-x}Ga_x$ and $V_{1-x}Si_x$ has been measured as a function of the composition x and the temperature in the normal state. The V and Pt respectively Ga states are found to be strongly admixed. The experimental results indicate that the major contribution to the density of states at the Fermi energy $N(E_F)$ originates from the V 3d conduction electrons. This contribution, $N_d^V(E_F)$, exhibits a maximal value for the stoichiometric composition ($x=0.25$) in the systems investigated. Moreover, the anomalous temperature dependence of $N(E_F)$, typical for A-15 compounds, is largest for $x=0.25$. Both composition and temperature dependence of $N_d^V(E_F)$ can be explained with a simple model, using the results of recent band structure calculations on stoichiometric A-15 compounds. (14 refs.)

108827 Unusual isotope effects for diffusion in $VH_{0.50}$ and $VT_{0.50}$. R.C.Bowman,Jr., A.Attalla, B.D.Craft (Monsanto Res. Corp., Miamisburg, OH, USA).
Scr. Metall. (USA), vol.17, no.7, p.937-42 (July 1983).
NMR experiments were performed on vacuum encapsulated $VH_{0.50}$ and $VT_{0.50}$ powders. High purity vanadium metal was used to prepare both samples where stoichiometries are equal within an uncertainty of ±0.005. The nuclear relaxation times were measured by conventional pulse techniques. Proton relaxation times for $VH_{0.50}$ were measured between 100K and 520K and are presented. Triton relaxation times for $VT_{0.50}$ between 100K and 450K are summarized. (16 refs.)

108828 Critical slowing down of fluctuations in *p*-terphenyl and *p*-quaterphenyl observed by proton spin-lattice relaxation. B.Toudic, J.Gallier, P.Rivet, H.Cailleau (Univ. de Rennes I, Rennes, France).
Solid State Commun. (USA), vol.47, no.4, p.291-5 (July 1983).
The temperature evolution of the proton spin-lattice relaxation time T_1 in *p*-terphenyl and in *p*-quaterphenyl around their order-disorder phase transition has been measured. In both cases pretransitional collective fluctuations destroy the high temperature Arrhenius behaviour of the relaxation rate corresponding to a single reorientational jump motion. The spin-lattice relaxation times present then a drastic decrease until the transition temperature ($T_0=193$K in *p*-terphenyl, $T_0=238$K in *p*-quaterphenyl). This decrease is associated to the critical slowing down of fluctuations. In the low temperature phase the ordering phenomena lead to a sharp drop of the spin-lattice relaxation rate. (19 refs.)

76.60G Quadrupole resonance

108829 Diffusion-induced quadrupole relaxation of ^{27}Al nuclei in dilute Al-Ti, Al-Cr, Al-Mn, and Al-Cu alloys at high temperatures. L.Bottyan (Dept. of Materials Sci., Hungarian Aluminium Corp., Budapest, Hungary), D.L.Beke, K.Tompa.
Phys. Status Solidi b (Germany), vol.118, no.2, p.835-42 (1 Aug. 1983).
The temperature dependence of the laboratory frame spin-lattice relaxation time of ^{27}Al nuclei is measured in 5N Al and in dilute Al-Ti, Al-Cr, Al-Mn, and Al-Cu alloys at 5.7 and 9.7 MHz resonance frequencies. The relaxation in pure aluminium is found to be purely due to the conduction electrons. An excess T_1-relaxation contribution is detected in all Al-3d alloys investigated above 670K. The excess relaxation rate is proportional to the impurity content and the temperature dependence of the excess contribution is of Arrhenius-type with an activation energy of (1.3 ± 0.3) eV for all of the investigated alloys. The relaxation contribution is found to be quadrupolar in origin and is caused by the relative diffusional jumps of solute atoms and Al atoms relatively far from the impurity. (30 refs.)

108830 Study of rubidium hydroselenite by NMR of ^{87}Rb and ^2D. A.I.Roslyakov, I.S.Vinogradova (Inst. of Phys., Acad. of Sci., USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.1, p.99-100 (Jan.-Feb. 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.1, p.175-7 (Jan.-Feb. 1983). [received: Sept. 1983]
Uses nuclear magnetic resonance (NMR) to make a systematic investigation of the hydroselenite family $MHSeO_3$. The authors discuss the determination of the nuclear quadrupole interaction constants of rubidium and deuterium and the lengths and direction cosines of the hydrogen bonds in $RbHSeO_3$, and seek the phase transitions. (7 refs.)

76.60L Spin echoes

108831 A note on the signal intensity of the second spin echo in Carr-Purcell-Meiboom-Gill sequence of turbulent flows. Y.Kawabe, K.Fukuda, A.Hirai (Dept. of Phys., Kyoto Univ, Kyoto, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2308-11 (July 1983).
In the study of turbulent flows by a pulsed NMR method, the signal intensity of the second spin echo in a Carr-Purcell-Meiboom-Gill sequence is measured as a function of the magnetic field gradient. A theoretical expression for the signal intensity has been obtained which seems to explain the experimental data, particularly the dependence of the signal intensity on the magnetic field gradient, more satisfactorily than the previous models. (6 refs.)

108832 Anomalous behavior of ^{19}F NMR signals in K_2CuF_4 at ultralow temperatures. M.Fujii, A.K.Hirai (Dept. of Phys., Kyoto Univ., Kyoto, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2898-9 (Aug. 1983).
^{19}F NMR in a two dimensional Heisenberg ferromagnet K_2CuF_4 has been studied down to 30 mK at zero or small external fields. Below 1K the NMR signals show anomalous behavior, which can be explained satisfactorily, by solving the coupled equations of motion for four ^{19}F nuclear spins and an electron spin, whose ferromagnetic resonance frequency is nearly equal to zero. Furthermore, below 90 mK, a new strong spin echo signal appeared at 54.5 MHz under a slightly different excitation condition. The origin and nature of this new signal is difficult to understand at present. (17 refs.)

108833 NMR study of the orientational ordering of monolayers of $^{15}N_2$ on graphite. N.S.Sullivan, J.M.Vaissiere (Service de Phys. du Solide et de Resonance Magnetique, CENS, Gif-sur-Yvette, France).
Phys. Rev. Lett. (USA), vol.51, no.8, p.658-61 (22 Aug. 1983).
NMR pulse techniques have been used to study the orientational ordering of $^{15}N_2$ molecules physisorbed on graphite. A small hysteresis ($\sim$2.5%) and small discontinuity in the evolution of the NMR echo amplitudes which depend directly on the local order parameters indicates that the order-disorder transition is first order. (26 refs.)

108834 Oscillations of NMR-echo signals in antiferromagnets. Ya.Ya.Asadullin.
Ukr. Fiz. Zh. (USSR), vol.28, no.8, p.1208-13 (Aug. 1983). In Russian.
A theory of NMR-echo in antiferromagnets is given with account of nonlinear mechanisms of three types: excitation, damping and dispersion. Oscillations of the echoes are predicted and explained. Their significance for determination of unknown parameters of the system is discussed. The displacement of the echo appearance time and 'capture' echo are also explained. It is shown that the oscillations mentioned are inherent in a class of echo phenomena in solids, gases and plasmas. (9 refs.)

76.70 MAGNETIC DOUBLE RESONANCES AND CROSS EFFECTS

76.70D Electron-nuclear double resonance (ENDOR)

108835 Transferred hyperfine interactions between ^{25}Mg nuclei and neighbouring Cr^{3+} impurities in magnesium oxide [ENDOR study]. P.Freund (Clarendon Lab., Univ. of Oxford, Oxford, England).
J. Phys. C (GB), vol.16, no.25, p.5039-51 (10 Sept. 1983).
Using the ENDOR technique, magnetic hyperfine and quadrupole interactions of ^{25}Mg nuclei close to Cr^{3+} and Ni^{2+} substitutional impurities in MgO have been measured. The results are discussed in terms of the amount of unpaired spin in the Mg^{2+} orbitals. It is shown that the size of the isotropic part of the magnetic hyperfine interaction is explained better if the Mg^{2+} 1s orbitals are included in the calculation that if only the outer, 2s orbitals are used. The anisotropic part is described well by a combination of the effects of the magnetic dipole interaction and the overlap of Mg^{2+} 2p orbitals with O^{2+} orbitals containing unpaired spin. The quadrupole interactions can only be partly analysed because of insufficient information but it is shown that charge transfer only accounts for a small part of the observed interactions. (20 refs.)

108836 Spin density distribution in cobaltocene: a proton ENDOR study on $Co(cp)_2$ diluted in $Mn(cp)(CO)_3$ single crystals. M.Rudin, J.M.Fauth, A.Schweiger, R.R.Ernst (Lab. for Phys. Chem. ETH, Zurich, Switzerland), L.Zoller, J.H.Ammeter.
Mol. Phys. (GB), vol.49, no.6, p.1257-75 (20 Aug. 1983).
In order to obtain information on the spin density distribution in cobaltocene $(CO(cp)_2)$ at low temperature, a single crystal proton ENDOR study of $Co(cp)_2$ doped $Mn(cp)(CO)_3$ has been carried out. The hyperfine tensors of all ten ring protons have been determined. These data indicate that the molecular symmetry of $Co(cp)_2$ is almost D_{5h}, i.e. the two cp rings are eclipsed. The isotropic hyperfine couplings reflect approximate $C_{2v}(y)$ symmetry of the spin density distribution and hence support a ground state with predominant d_{xz} character. Both isotropic and dipolar proton hyperfine couplings have been used to derive the spin densities at the adjacent carbon centres. These results show that the isotropic proton coupling is mainly due to polarization of the proton 1*s* orbitals and that direct contributions from σ-spin density on the cp rings are of minor importance. The spin densities in the carbon $2p_z$ orbitals derived from proton ENDOR data are compared to those calculated from EPR (g-tensor) and HMO results. Discrepancies which have been found are, among other reasons, due to the fact that the experimental spin density distribution shows only approximately $C_{2v}(y)$ symmetry. To account for this low symmetry, orbital mixing of the d_{xz} and d_{yz} orbitals has been considered. (43 refs.)

Two types of F centres in alkaline earth fluoro-halides. I. Superhyperfine interactions and electronic structure .... See Entry 107693

76.70F Double nuclear magnetic resonance (DNMR)

108837 Double resonance saturation recovery in 2,6-lutidine. K.Mizuno, M.Ishiwata (Inst. for Solid State Phys., Univ. of Tokyo, Tokyo, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2918-21 (Aug. 1983).
The time variation of the longitudinal magnetization of an individual A-proton line in an AB_2-proton system in 2,6-lutidine was observed by the saturation-recovery method under continuous irradiation of a second radio-frequency field to certain particular lines of the B protons. The stirring field was so weak that the spin-tickling effect caused no detectable splitting of the observed line. The dependence of the recovery time T_{H2} on the strength H_2 of the stirring field differs according to the combination of the observed and the stirred lines; as H_2 increases, the T_{H2} for regressively connected lines increases monotonically, that for unconnected lines hardly changes, and that for progressively connected lines decreases at first and then increases. (8 refs.)

Spin-lattice relaxation of ^{13}C in solid amino acids using the CP-MAS technique .... See Entry 108819

76.70H Optical double magnetic resonance (ODMR)

108838 Optical and optically detected magnetic resonance studies of AgBr:I$^-$. A.P.Marchetti, M.S.Burberry (Res. Labs., Eastman Kodak Co., Rochester, NY, USA).
Phys. Rev. B (USA), vol.28, no.4, p.2130-5 (15 Aug. 1983).
Low-temperature emission and optically detected magnetic resonance (ODMR) spectra of AgBr containing various amounts of iodide have been obtained. The ODMR spectrum at low iodide concentrations (1-100 p.p.m.) is assigned to transitions of the iodine-bound exciton. Time and wavelength evolution of the emission from high-iodide-concentration (~3 at.%) samples provides evidence for donor-acceptor recombination. ODMR spectra of high-iodide-concentration samples suggest an iodide-related hole trap. (21 refs.)

108839 ODMR study of the nature of iron-red photoluminescence in ZnS crystals. M.Godlewski (Inst. of Phys., Polish Acad. of Sci., Warsaw, Poland).
Solid State Commun. (USA), vol.47, no.10, p.811-13 (Sept. 1983).
Based upon the ODMR (optically detected magnetic resonance) measurements on the so-called iron-red (Fe-R) luminescence in ZnS it is shown that the emission is due to the radiative capture of either free or weakly bound electron by substitutional Fe^{3+} associated with an unknown defect residing in n.n. Zn position. (12 refs.)

76.80 MÖSSBAUER EFFECT; OTHER GAMMA-RAY SPECTROSCOPY

108840 Mossbauer study of cage motion in Ag^{57}Co/^{57}Fe. I.Sakamoto, B.Furubayashi, W.Petry.
Bull. Electrotech. Lab. (Japan), vol.47, no.6, p.489-96 (1983). In Japanese.
It has been observed that ^{57}Co/^{57}Fe atoms in 3 MeV e^- irradiated Ag have moved restrictively within a cage near 60K. An application in the investigation of radiation damage by a method making use of cage motion is described. (17 refs.)

108841 Preliminary study of the recoil implanted perturbed angular distribution. H.Watanabe, H.Sekiguchi.
Bull. Electrotech. Lab. (Japan), vol.47, no.6, p.497-504 (1983). In Japanese.
The internal magnetic field of ferromagnetic materials has been measured by the integral perturbed angular correlation method following a low energy ^{53}Mn recoil implantation into the ferromagnetic materials by the resonant proton capture reaction $^{52}Cr(p,\gamma)^{53}Mn$. The experimental method and results are given. (15 refs.)

108842 Mossbauer effect of ^{57}Fe impurity atoms in TiAl. I.A.Zelenkov, S.N.Pastushenko (Inst. of Civil Aviation Engng., Kiev, Ukrainian SSR).
Phys. Met. (GB). Translation of: Metallofizika, Kiev (USSR), vol.4, no.3, p.610-14 (1982). [received: Aug. 1983]
The purpose of the present study was to examine the hyperfine structure of Mossbauer absorption spectra from ^{57}Fe impurity atoms (0.3%) and to elucidate the local neighborhood and distribution of Fe atoms in TiAl sublattices. Mossbauer spectra of powdery specimens were taken on a YaGRS-4 spectrometer with constant accelerations using a multichannel pulse analyzer. It is concluded that Fe impurity atoms in the matrix of the stoichiometric TiAl metallide tend to occupy Al sites. This results in a greater amount of Fe-Ti bonds and may indicate that there is a higher covalency in the Fe-Ti interatomic bond and a greater Fe-Ti interaction energy as compared to that of Fe-Al interaction. Near the melting point Fe atoms with equal probability replace Al and Ti sites in an ordered TiAl matrix, which is stronger than between the atoms of the matrix and impurity. (3 refs.)

108843 Mossbauer and magnetisation studies of the alloy $Fe_{0.69}Pd_{0.31}$. N.V.Nair, D.C.Khan (Dept. of Phys., Indian Inst. of Technol., Kanpur, India).
J. Phys. F (GB), vol.13, no.9, p.1965-72 (Sept. 1983).
The authors report Mossbauer and magnetisation studies of the alloy $Fe_{0.69}Pd_{0.31}$ with special emphasis on the FCC-FCT martensitic transformation. The transition temperature of 184K is determined from the $T^{3/2}$ dependence of the quadrupole splitting which undergoes a change in slope after the transformation. The hyperfine field distribution in the FCC phase at various temperatures shows a steady increase in the distribution width with temperature, which indicates a short-range order in the material. The recoilless fraction of the material is determined using the method of Trooster et al. (1978) and the value of f_a obtained at room temperature is 0.568 in this alloy. (9 refs.)

108844 ^{121}Sb Mossbauer study of some lithium thioantimonates. J.-C.Jumas, J.Olivier-Fourcade, E.Philippot, M.Maurin (Lab. de Chimie Minerale C, Univ. des Sci. et Tech. du Languedoc, Montpellier, France).
J. Solid State Chem. (USA), vol.49, no.1, p.6-13 (Aug. 1983). In French.
Antimony 121 Mossbauer spectra have been recorded at liquid-helium temperature for ternary sulfides isolated from the Li_2S-Sb_2S_3 system. The chemical isomer shifts observed (−6.22 to −3.50 mm/sec relative to InSb at 78K) are characteristic of antimony (III) compounds. The Mossbauer data are discussed in relation to their known structures with regard to the stereochemical activity of the antimony (III) lone pair of electrons. (20 refs.)

108845 A Mossbauer study of the κ phase in the Fe-W-C system. P.Jernberg, R.Wappling (Inst. of Phys., Univ. of Uppsala, Uppsala, Sweden).
J. Solid State Chem. (USA), vol.49, no.1, p.123-5 (Aug. 1983).
It is shown that, taking the absorber thickness properly into account, reliable values of the iron population of the different sites in κ-(Fe-W-C) can be obtained although the resolution in the Mossbauer spectrum is limited. The partial population of one 2*a* crystallographic position was determined to be $40\pm2\%$ in good agreement with the value $45\pm1\%$ obtained from a recent diffraction study. (5 refs.)

108846 Contribution of the direct B-B interaction to the supertransferred hyperfine field at diagmagnetic antimony in oxidic spinels determined by ^{121}Sb Mossbauer spectroscopy. G.Dehe, U.Behn (Sektion Phys., Karl-Marx-Univ. Leipzig, Leipzig, Germany).
Phys. Status Solidi a (Germany), vol.78, no.2, p.485-8 (16 Aug. 1983).
By studying the magnitude of the magnetic hyperfine splitting in the ^{121}Sb Mossbauer spectrum, the substitution of nominally diagmagnetic Sb^{5+} ions in oxidic spinels is suitable for determining the strength of the contribution of the different magnetic interactions, producing the supertransferred hyperfine field. The samples $ZnNi_{2/3}FeSb_{1/3}O_4$ and $Ni_{5/3}FeSb_{1/3}O_4$ are prepared and ^{121}Sb Mossbauer spectra at room temperature with and without a transverse external magnetic field are recorded and analyzed. In the $ZnNi_{2/3}FeSb_{1/3}O_4$ sample a contribution due to covalency mixing by a direct cation-cation orbital combination of about 10% of the contribution due to a polarizing mechanism via the intermediate ligands is proved. It can be shown that there is a certain temperature region above the Neel temperature (T_N) in which ^{121}Sb nuclei are still sensitive to the magnetic ordering in the sample, whereas ^{57}Fe nuclei are not sensitive to it. (7 refs.)

108847 Quadrupole interaction of tantalum impurities in bismuth metal. S.N.A.Jaaffrey, J.Varma (Phys. Dept., Univ. of Udaipur, Udaipur, India).
Pramana (India), vol.20, no.5, p.387-92 (May 1983).
The time differential perturbed angular correlation technique has been used in the measurement of the electric quadrupole interaction of Ta impurity in bismuth metal. The interaction frequencies at 293, 400 and 500K have been observed to be 288 ± 1.5, 266.0 ± 3 and 244.5 ± 4.3 MHz respectively. The electric field gradient at 293K is $4.75\pm0.3\times10^{17}$ V/cm^2 with the temperature coefficient $B=2.2\pm0.2\times10^{-5}(K)^{-3/2}$. (26 refs.)

108848 ^{151}Eu isomer shifts and charge transfer in Eu-base intermetallic compounds. J.W.C.de Vries, R.C.Thiel (Kamerlingh Onnes Lab., Rijksuniv. Leiden, Leiden, Netherlands), K.H.J.Buschow.
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.100-8 (1983).
The ^{151}Eu isomer shift found in various divalent Eu compounds have been analysed by means of the model proposed earlier for the ^{197}Au isomer shift in Au-base materials by Miedema and Van der Woude (1980). Relative changes of 5d and 6s electron occupation numbers due to alloying of divalent Eu with other elements were deduced from this analysis and compared with electronic properties reported for such compounds in the literature. (23 refs.)

108849 The Mossbauer effect on ^{119}Sn nuclei in vanadium, platinum and niobium. R.B.Yadav (Phys. Dept., Memorial Univ. of Newfoundland, St. John's, Newfoundland, Canada).
Solid State Commun. (USA), vol.47, no.4, p.267-8 (July 1983).
The probabilities for recoilless resonant absorption of 23.8 keV γ-rays by ^{119}Sn in matrices of vanadium, platinum and niobium have been calculated in the temperature ranges 80-400K. The calculated results show a good agreement with the experimental data. (13 refs.)

108850 Mossbauer studies of defect-impurity interaction and impurity diffusion in metals. G.Vogl, W.Petry, K.Sassa (Hahn-Meitner-Inst., Berlin, Germany), S.Mantl.
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.33-40
On the basis of the earlier determination of the characteristic Mossbauer spectra of ^{57}Co/^{57}Fe impurities with tapped interstitials or vacancies in aluminium, point defects produced by plastic deformation and neutron or ion irradiation have been studied. In plastically deformed aluminium vacancy migration was found at temperatures well below stage III, whereas no freely migrating interstitials were detected. The diffusion of Fe impurity atoms in

aluminium has also been investigated. From Mossbauer studies on a single crystal specimen the elementary diffusion jump was determined. It has further been possible to detect and investigate special jump processes due to interstitial-impurity binding (impurity jumps in a cage) and vacancy-impurity binding. (31 refs.)

108851 ^{57}Fe Mossbauer study on point defects in pure iron. Y.Yoshida, S.Nasu, F.E.Fujita (Dept. of Material Phys., Osaka Univ., Osaka, Japan).
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.199-202
The study of the point defects in neutron irradiated pure iron is performed by using the normal transmission and new thermal scan method in the Mossbauer source experiment. Clear annealing stages below 110K and around 200K are found in the measurements of the count-rate, total resonance area, average hyperfine field and full width at half maximum. These temperatures may correspond to the recovery of interstitials and vacancies, respectively. (8 refs.)

108852 Theory of Mossbauer line broadening due to diffusion. K.Schroeder (Inst. fur Festkorperforschung, KFA Julich, Julich, Germany), D.Wolf, P.H.Dederichs.
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.570-3
The authors have calculated the line broadening of the Mossbauer line due to diffusion of Mossbauer atoms via single vacancies. They take into account the perturbation of vacancy jumps in the neighbourhood of an impurity Mossbauer atom (e.g. Fe in Al) using the 5-frequency model. The anisotropy of the line width is given by the Fourier transform of the final distribution of a Mossbauer atom after an encounter with a vacancy. This distribution is calculated by Monte Carlo computer simulation. (17 refs.)

77.20 PERMITTIVITY

108853 Evaluation of dielectric permittivity by DC transient current. S.Yagihara, R.Nozaki, S.Takeishi, S.Mashimo (Dept. of Phys., Tokai Univ., Kanagawa, Japan).
J. Chem. Phys. (USA), vol.79, no.5, p.2419-22 (1 Sept. 1983).
Inverse Laplace transformation of the Havriliak-Negami (HN) equation (1967) of complex dielectric permittivity has been obtained analytically both in short time and long time regions. A convenient procedure for determining the relaxation parameters in the HN equation from the DC transient current has been presented. Even if the current measurement is not carried out over the whole time range but only in a restricted time range, this procedure gives satisfactory values to the relaxation parameters. (33 refs.)

108854 Dielectric susceptibility and thermal hysteresis in K$_2$SeO$_4$ and Rb$_2$ZnCl$_4$. H.Mashiyama, H.-G.Unruh (Fachrichtung Experimentalphys., Univ. des Saarlandes, Saarbrucken, Germany).
J. Phys. C (GB), vol.16, no.25, p.5009-16 (10 Sept. 1983).
The dielectric constant of potassium selenate and rubidium tetrachlorozincate is measured in the temperature range including the incommensurate phase. The inverse susceptibility obeys the Curie-Weiss law in a certain temperature region above the lock-in temperature. The thermal hysteresis of the susceptibility is interpreted as being caused by pinning effects on the incommensurate modulation in the crystal and consequences thereof are explained by using the Landau-type free energy. (15 refs.)

108855 Some comments on the complex permittivity of ellipsoids dispersed in continuum media. C.Boned, J.Peyrelasse (Dept. de Phys., Inst. Univ. de Recherche Sci., Univ. de Pau et des Pays de l'Adour, Pau, France).
J. Phys. D (GB), vol.16, no.9, p.1777-84 (14 Sept. 1983).
Complex permittivity equations have been derived using the Bruggeman method at high volume fractions for a random distribution of ellipsoids dispersed in a continuous medium. (24 refs.)

108856 Estimation of permittivity of a compact crystal by dielectric measurements on its powder: A stochastic mixture model for the powder-dielectric. P.S.Neelakantaswamy, B.V.R.Chowdari, A.Rajaratnam (Dept. of Phys., Faculty of Sci., Nat. Univ. of Singapore, Singapore).
J. Phys. D (GB), vol.16, no.9, p.1785-99 (14 Sept. 1983).
A stochastic mixture model is proposed for the dielectric formed by the powder of an isotropic polycrystalline material included in an embedding medium of air or a non-polar substance. The relevant expression of the complex dielectric constant of the mixture is obtained in terms of the dielectric parameters of the mixture constituents and the volume fraction of the crystalline material. Hence the possibility of deducing the dynamic state dielectric characteristics of the solid (compact) crystal from the measured data on the powder is indicated. Theoretical results obtained for 1-cyanoadamantane using the present model over a wide spectral range (1 kHz to 1 GHz) are compared with corresponding experimental data available elsewhere. Results due to the present method agree more closely with the measured values for both low and high volume fractions, when compared with the results based on other existing models due to Bottcher and Looyenga. (10 refs.)

108857 Observation of dielectric collapse at excited acceptors in germanium. V.I.Bocharnikov, E.E.Godik, A.V.Petrov (Inst. of Radio Engng., & Electronics., Acad. of Sci., USSR).
JETP Lett. (USA), vol.37, no.6, p.306-8 (20 March 1983). Translation of: *Pis'ma v Zh. Eksp. & Teor. Fiz. (USSR)*, vol.37, no.6, p.259-61 (20 March 1983). [received: Sept. 1983]
The dielectric constant of germanium is found to display a superlinear dependence on the concentration of photoexcited impurities. It is shown that the observed effect is due to the growth of the polarizability of the excited centers as a result of their interaction. (5 refs.)

108858 Dielectric properties of alkali halides using Mott-Littleton polarization theory. J.Shanker, R.Sundaraj (Phys. Dept., Agra Coll., Agra, India).
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.175-80 (1983).
Some new relations between the electronic and static dielectric constants and the transverse optical mode frequency are obtained using the Mott-Littleton expressions (1938) for effective polarization fields. The usefulness of these relations is demonstrated, in explaining the dielectric behaviour of alkali halide crystals under the effect of pressure, by calculating the volume derivatives of dielectric constant and transverse optical mode Gruneisen parameter. 77.30 POLARIZATION AND DEPOLARIZATION EFFECTS

108859 Thermostimulated depolarization currents on a glass surface in ambient gases. B.Despax, C.Huraux, R.Lacoste, M.Abdullah (Lab. de Genie Electrique, Univ. Paul Sabatier, Toulouse, France).
J. Mater. Sci. (GB), vol.18, no.9, p.2544-54 (Sept. 1983).
Interdigital comb-shaped electrodes were used to observe thermostimulated depolarization currents flowing on a soda glass surface in ambient gases. The experimental set up, electrode shaping by photograving and measurement procedure are described. Surface thermostimulated depolarization current (STDC) spectra were recorded on glass specimens in carbon dioxide or helium. In both cases, after short gas residence times, depolarization currents were not different from those obtained in vacuum. Different STDC spectra were recorded as the residence time of a glass specimen in CO_2 was increased; these spectra also changed with polarization time and polarization temperature. In helium, STDC peaks were observed at −110°C and −90°C with a shoulder at −65°C. A discussion and an attempt to interpret the results in terms of charge injection in glass involving slow adsorption or absorption of the ambient gas are given. (7 refs.)

108860 Effect of iodine on depolarisation behaviour of polyvinyl fluoride (PVF) films. P.C.Mehendru, Suresh Chand (Nat. Phys. Lab., New Delhi, India).
J. Phys. D (GB), vol.16, no.9, p.L185-8 (14 Sept. 1983).
The depolarisation behaviour of PVF films doped with iodine (0-2.0% by weight) has been studied using the TSD technique. The TSD spectra of these films reveal two relaxation peaks. The peak positions, peak currents, charges and activation energies associated with the two peaks are strongly affected by the concentration of iodine and have been explained in terms of formation of charge transfer complexes and molecular aggregates. (12 refs.)

108861 Non-uniform polarization effects in DC stressed low-density polyethylene. D.K.Das-Gupta, K.Doughty, J.S.Duffy (School of Electronic Engng. Sci., Univ. Coll. of North Wales, Bangor, Wales), D.E.Cooper.
J. Electrostat. (Netherlands), vol.14, no.2, p.165-74 (Aug. 1983).
Thermal current transients have been measured in untreated and hexane-treated low-density polyethylene as a function of electrical pre-stress. The results indicate a significant non-uniform polarization which is moderated by increasing fields in a complex manner. (30 refs.)

108862 A relationship between the universal law of susceptibility response and the correlation weakening principle. R.R.Nigmatullin, R.M.Hill (Dept. of Phys., Chelsea Coll., Univ. of London, London, England).
Phys. Status Solidi b (Germany), vol.118, no.2, p.769-78 (1 Aug. 1983).
The observation of the universal response of electrical, mechanical, acoustic, and magnetic systems in which power law behaviour in the time and frequency domains is seen indicates the universal behaviour of correlation functions in these systems. It is shown that this behaviour can be obtained by making use of the correlation weakening principle which plays an essential role in quantum-statistical physics and which does not depend on the detailed structure of the many-body system involved. (23 refs.)

108863 Thermally stimulated depolarisation currents in $Ce_2(SO_4)_3.9H_2O$. A.Torres, J.Jimenez, V.Carbayo, J.A.De Saja (Lab. de Fisica del Estado Solido, Facultad de Ciencias, Valladolid, Spain).
Phys. Status Solidi a (Germany), vol.78, no.2, p.671-7 (16 Aug. 1983). In French.
The results shown in this paper for $Ce_2(SO_4)_3.9H_2O$ and $Ce_2(SO_4)_3.9D_2O$ single crystals, are a part of a general study of the physical properties of lanthanide (III) sulfate hydrates. From TSDC (thermally stimulated depolarization current) and TSPC (thermally stimulated polarization current) studies of hydrated and deuterated single crystals one can deduce that the current arises from dipole relaxation which may be related to the hydrogen or deuterium atoms (hydrogen bonds). The experimental set-up is described in detail. (20 refs.)

108864 The generalization of the Debye equation and its application to the electrets study. R.M.Neagu (Phys. Dept., Polytechnic Inst. of Jassy, Jassy, Rumania).
Rev. Roum. Phys. (Rumania), vol.28, no.6, p.547-53 (1983).
In order to generalize the Debye equation the reaction field of a dipole and the internal field, deduced by Onsager, are considered. This equation describes the behaviour of a dielectric which contains polar molecules, under the influence of an electric field which varies in time. Starting from this equation the author obtains the equations which describe the charge and the discharge of a thermoelectret during the thermostimulated discharge (TSD). (7 refs.)

77.40 DIELECTRIC LOSS AND RELAXATION

108865 Secondary amines: a low-temperature dielectric relaxation study. J.Gilchrist, H.Godfrin (Centre de Recherches sur les Tres Basses Temperatures/CNRS, Grenoble, France).
Chem. Phys. (Netherlands), vol.79, no.2, p.307-20 (1 Sept. 1983).
Polyethylene matrices containing dibutylamine and dioctylamine were studied at temperatures down to 4.4 mK, and the mean inversion splitting of each amine was estimated to be 425±25 MHz. This result prompted a new study of some thiophenol derivatives from which it is concluded that internal-rotation barriers and inversion barriers both tend to be a little higher (on the order of 100 cm^{-1}) in hydrocarbon matrices than in the vapours. An unexplained non-linearity of the dielectric response at sub-Kelvin temperatures was investigated by superposing alternating voltages of different frequencies. Thirty other secondary amines and similar compounds were also examined to evaluate the effects on nitrogen inversion of bulky alkyl groups, neighbouring π-bonds and ring strain. Derivatives of allylamine, benzylamine and pyrrolidine apparently had alternative configurations distinguished by markedly different inversion rates. The proportions depended on the matrix, polyethylene or polypropylene, as well as on the derivative. (34 refs.)

108866 Temperature dependence of dielectric properties of water. II. Absorption cell method. A.M.Gazimuddin (Phys. Dept., Coll. of Sci., Univ. of Basrah, Basrah, Iraq).
Proc. Pak. Acad. Sci. (Pakistan), vol.19, no.1, p.37-55 (1982).
The time of relaxation of water molecules at microwave frequencies is directly related with the structure of liquid water according to the concept of hydrogen-bonds bending, breaking and reforming. The effects of temperature on the relaxation time are the changes in the freedom of orientation of water molecules in the changing electric field. Therefore, the relaxation phenomenon is considered as a kind of rate process. It is demonstrated experimentally that there are 'structure temperatures' or 'thermal anomalies' in the temperature variation of $\Delta I(M,N)T$, which are directly due to the structures in $\epsilon''(T)$ and $\zeta(T)$ of the liquid water. These structural anomalies suggest that the structure of liquid water may not be homogeneous at all temperatures. From the idea of microcrystalline domains, it is proposed that there are different types of not easily interconvertible domain structures existing in liquid water and each particular one favoured over a narrow range of temperature. (12 refs.)

108867 Low-temperature dielectric properties of ceramic potassium tantalate ($KTaO_3$). Z.X.Chen, X.L.Zhang, L.E.Cross (Materials Res. Lab., Pennsylvania State Univ., University Park, PA, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.511-15 (July 1983).
Dielectric properties of $KTaO_3$ ceramic fabricated by both conventional sintering and sintering followed by isostatic hot pressing (HIP) were measured at T=4.2 to 300K over a frequency range from 400 Hz to 4 MHz. The weak field response shows a faint peak near 10K which has a clear relaxation character, as in high-purity single crystals. The general response is well reproduced by the Barrett function, but additional polarizability with relaxation character is also in evidence at higher temperatures. No dielectric hysteresis was observed at high fields for cycling frequencies down to 0.04 Hz anywhere in the temperature range. (16 refs.)

108868 Low-frequency dielectric loss of triglycine sulfate. E.Courtens (IBM Zurich Res. Lab., Ruschlikon, Switzerland), R.Garcia, J.A.Gonzalo.
Phys. Rev. Lett. (USA), vol.51, no.9, p.844-5 (29 Aug. 1983).
Discusses the observation of Ising dipolar critical behaviour of TGS with dielectric loss measurements performed at 1 kHz by Garcia and Gonzalo (1983). It is shown that the procedure of equating the q-dependent static susceptibility with a phenomenological dynamic response is not physically well founded and leads to numerical inconsistencies. (12 refs.)

108869 Dielectric relaxation in the crystalline smectic-*B* phase. L.Benguigui (Solid State Inst., Technion-Israel Inst. of Technol., Haifa, Israel).
Phys. Rev. A (USA), vol.28, no.3, p.1852-4 (Sept. 1983).
The author measured the parallel dielectric relaxation in pentoxybenzlidene octylaniline (5O.8), in the nematic, smectic-*A*, and smectic-*B* phase. This last phase is characterized by a low-frequency relaxation with a small activation energy. Although the Sm-*B* has a three-dimensional positional ordering, the molecules are mobile as in the nematic and Sm-*A* phases. (11 refs.)

108870 Dielectric and electrical properties of SnO_2, Sb_2O_3, and their mixed films. J.S.Kumar, G.Narayana, M.C.Shekar, U.V.Subba Rao, V.H.Babu (Dept. of Phys., Osmania Univ., Hyderabad, India).
Phys. Status Solidi a (Germany), vol.78, no.2, p.647-553 (16 Aug. 1983).
The dielectric and electrical properties of sandwiched Al-SnO_2-Al, Al-Sb_2O_3-Al, and Al-(SnO_2+Sb_2O_3)-Al structures of different thicknesses are investigated. The AC capacitance and tan δ increase with decrease in frequency in all these films. A comparison of the capacitance values of these films shows that the values of the capacitance are larger in mixed films as compared to the values of capacitance in SnO_2 and Sb_2O_3 films. The variation of tan δ with frequency for mixed films lies between to that of SnO_2 and Sb_2O_3 films. Current-voltage characteristics of these films show that the breakdown voltage increases and the dielectric strength decreases with increase in film thickness in all the three types of films. The logarithm of breakdown field strength is plotted against the logarithm of the film thickness for the three types of films. Photomicrographs of the breakdown patterns at different stages of voltage are given and the results are explained. (15 refs.)

108871 Dielectric relaxation study of the incommensurate phase of $[(CH_3)_4N]_2CuBr_4$ near the transition temperature. R.Jakubas, L.Sobczyk (Inst. of Chem., Univ. of Wroclaw, Wroclaw, Poland).
Phys. Status Solidi a (Germany), vol.78, no.2, p.K147-50 (16 Aug. 1983).
Reports the results of $\epsilon^*(\omega)$ measurements for a crystal showing interesting incommensurate properties: $[(CH_3)_4N]_2CuBr_4$ (TMATB-Cu). The $\epsilon''(T)$ maxima at lower frequencies are shifted below T_c. This effect is reproducible and beyond the limits of experimental error. At higher frequencies, the maxima of permittivity and losses shift to higher T values reflecting a typical critical slowing down. The Cole-Cole diagram shows a considerable distribution of the relaxation time independently of the distance from the transition point. (9 refs.)

108872 Dielectric relaxation in networks of end-linked dimethylsiloxane oligomers. M.Naoki, S.Kondo (Faculty of Technol., Gunma Univ., Gunma, Japan).
Polymer (GB), vol.24, no.9, p.1139-44 (Sept. 1983).
Networks composed of very short dimethylsiloxane chains were prepared by end-linking dimethylsiloxane oligomers with a tetrafunctional crosslinking agent. Their dielectric properties were studied to elucidate the effects of crosslinks on molecular motion in highly crosslinked networks. The temperature of maximum loss for the primary relaxation process (α process) shifted greatly to high temperature with decrease in the chain length between crosslinks. The activation energy and the width of the absorption curve increased with decrease in chain length. No linear relation existed between the dielectric properties for the α relaxation and the crosslink density. On the other hand,

the temperature of maximum loss for the secondary relaxation process (β process) shifted to high temperature with decreasing chain length, but the activation energy was almost independent of the chain length. Characteristics for the α, β and hypersonic relaxations in the networks are discussed in terms of inter- and intramolecular contributions. (37 refs.)

108873 Electrical relaxation in pure and alkali metal thiocyanate complexed poly(ethylene oxide). J.J.Fontanella, M.C.Wintersgill, J.P.Calame (Phys. Dept., US Naval Acad., Annapolis, MD, USA), C.G.Andeen.
Solid State Ionics (Netherlands), vol.8, no.4, p.333-9 (July 1983).
Audio frequency complex admittance and DSC studies have been performed on pure poly(ethylene oxide) (PEO) and PEO complexed with alkali metal thiocyanates over the temperature range 5.5-380K. The dielectric constant of the complexed materials is found to be greater than for pure PEO. A discontinuity in the conductivity is found which increases in temperature as the size of the cation increases. In every case, the discontinuity is associated with a feature in the DSC results. Next, some evidence is given that water may enhance the formation of amorphous complexed PEO. In pure PEO, α_a and γ relaxations are observed in good agreement with previous work. A thermal anomaly is found corresponding to α_a. In addition, α_c is identified in pure PEO. Very little difference is found for the γ relaxation between pure PEO and PEO-LiSCN and PEO-NaSCN. For PEO-KSCN, three distinct peaks are found in the γ relaxation region. These results are consistent with a $tg^{+}t \rightleftarrows tg^{-}t$ transition interpretation for γ where the cations reside within the helical channels at low temperatures. (41 refs.)

77.50 DIELECTRIC BREAKDOWN AND SPACE-CHARGE EFFECTS

108874 Electrical breakdown studies in didymium oxide thin films. G.Narayana, J.Siva Kumar, G.A.Badri Narayana, U.V.Subba Rao, V.Hari Babu (Dept. of Phys., Osmania Univ., Hyderabad, India).
Mater. Lett. (Netherlands), vol.2, no.1, p.63-6 (July 1983).
I-V characteristics of sandwiched Al-didymium oxide-Al structures are studied for different thicknesses. The breakdown voltage increases and the dielectric strength decreases with increase of film thickness. Optical photomicrographs of the breakdown patterns during different stages of DC voltage are taken and the results discussed. (18 refs.)

108875 Conditioning effect of dielectric breakdown in liquid helium. S.Kim, M.Terauchi, K.Yoshino, Y.Inuishi (Faculty of Engng., Osaka Univ., Osaka, Japan).
Jpn. J. Appl. Phys. Part 1 (Japan), vol.22, no.6, p.952-4 (June 1983).
In a non-uniform field with a needle-plane electrode system, the breakdown voltage V_b of a positive needle decreases as the number of breakdown events N increases, but that of a negative needle increases slightly with N. In a uniform field, the breakdown voltage decreases with increasing N. However, when the polarity of the voltage pulse is reversed after many breakdown events, V_b increases suddenly and then again decreases slightly with increasing N, tending to saturate. These conditioning effects can be explained by the increase of the electron injection from the cathode due to the formation of a rough surface by the previous breakdown events. (8 refs.)

108876 On the question of the maximum radius of destruction in the electrical breakdown of solid bodies. T.I.Alekseeva, V.I.Kurets, G.P.Filatov.
Elektron. Obrab. Mater. (USSR), no.3, p.54-7 (1983). In Russian. English translation in: *Electrochem. Ind. Process. & Biol. (GB)*
A method is proposed of evaluating the maximum radius of destruction in the electrical breakdown of dielectrics. Presented data of experimental studies on the destruction of specimens of a quartz ceramic confirm the adequacy of the proposed model. (8 refs.) *A.J.B.*

108877 Effect of heat treatment on dielectric strength of polyethylene terephthalate under compressive stress. C.H.Park, K.Okajima, M.Hara, M.Akazaki (Kyushu Univ., Kasuga, Japan).
IEEE Trans. Electr. Insul. (USA), vol.EL-18, no.4, p.380-9 (Aug. 1983).
Measurements of DC dielectric strength of polyethylene terephthalate (PET) film at room temperature are reported when it is heat set in silicone oil over a range of temperature between 60 to 200°C for durations of 1 and 60 min in order to control the degree of crystallinity of the sample. It is found that the DC dielectric strength under no mechanical stress increases with an increase in the degree of crystallinity, but the maximum dielectric strength under compressive stress at first increases with the degree of crystallinity, then reaches a maximum value, and decreases thereafter. For the samples heat treated near the glass transition temperature, which is about 70°C, the characteristics of dielectric strength under compressive stress are also varied significantly with heat treatment temperature and time although the crystallinity is constant. 108878 Observation of the existence of electrically excited purely mechanical resonance in piezoelectric and ferroelectric materials. P.J.Chen (Sandia Nat. Lab., Albuquerque, NM, USA).
Nuovo Cimento D (Italy), vol.2D, ser.1, no.4, p.1145-55 (July-Aug. 1983).
A displacement laser interferometer system has been adapted to measure the mechanical displacements of specimens of piezo-electric and ferroelectric materials driven by cyclic electric fields. It is found that mechanical resonances of quite large amplitudes can exist independent of any noticeable electrical disturbances. They are also detected in virgin and depoled specimens of ferroelectric ceramics. Preliminary experimental evidence suggests that this phenomenon depends on the domain structure of the ferroelectric materials. (7 refs.)

108879 Generalized thermoelastic wave propagation in an infinite piezoelectric solid. S.M.Sanjukta Ray, A.K.Pal (Dept. of Maths., Jadavpur Univ., Calcutta, India).
Rev. Roum. Phys. (Rumania), vol.28, no.6, p.513-23 (1983).
In problems of thermopiezoelectric interacvtions, since the derivation of the constitutive equations by Mindlin (1961), the classical coupled thermoelasticity theory is generally applied. Recently, more advanced thermoelasticity theories have been proposed taking into account the thermal relaxation parameters. In the present paper, the authors make use of these generalized theories to study the three-dimensional bulk wave propagation in an infinite piezoelectric medium of monoclinic symmetry. (9 refs.)

108880 Registration of macroscopic quadrupole effects in crystals. V.V.Gladkii (Inst. of Crystallography, Acad. of Sci., USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.2, p.191-5 (March-April 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.2, p.328-33 (March-April 1983). [received: Sept. 1983]
The author discusses various ways of registering electrical effects arising in crystals spontaneously or under external actions owing to changes in the macroscopic quadrupole moment (MQM). He describes methods of calculating all the MQM components from the results of measurements of the electric field at various points on the surface of the specimen. He lists the principal requirements imposed on the form and orientation of the specimens and on the configurations of the surface electrodes. (11 refs.)

108881 Acoustic body waves and electromechanical coupling coefficients in crystals of berlinite. B.I.Klimenko, N.V.Perelomova, V.S.Bondarenko (Inst. of Steel & Alloys, Moscow, USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.2, p.231-2 (March-April 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.2, p.392-3 (March-April 1983). [received: Sept. 1983]
Contains the results of computer calculations of the anisotropy of propagation and piezoelectric activity of acoustic body waves (ABW) in single crystals of berlinite $AlPO_4$. (3 refs.)

108882 A dynamic method of measuring piezoelectric constants. P.Buck, J.Reinhardt (Inst. fur Mineralogie, Univ. Marburg, Marburg, Germany).
Z. Kristallogr. (Germany), vol.163, no.3-4, p.233-41 (1983). In German.
A method for measuring piezoelectric constants by a dynamic method operating at frequencies of about 3-5 kHz is described. It is characterized by simple handling and evaluation of the piezoelectric constants d_{ijk} and their sign, high accuracy ($<1\%$) and the possibility of piezoelectric measurements of semiinsulating ($\rho \geq 10^9$ Ω cm) crystals. The method is based on the inverse piezoelectric effect. The piezoelectrically induced deformation of the test crystal is detected by a piezoelectric ceramic and compared with that of a standard crystal (α-quartz). Piezoelectric coefficients of some substances are redetermined. Values for the d_{ijk} of CdTe and $N_2H_5LiSO_4$ are given. (23 refs.)

108883 Electrostrictive and electro-optic properties of urea. L.Bohaty (Inst. fur Kristallographie, Univ. zu Koln, Koln, Germany).
Z. Kristallogr. (Germany), vol.163, no.3-4, p.307-9 (1983).
Urea, $CO(NH_2)_2$, point group $42m$, exhibits strong nonlinear optical coefficients (Kurtz and Perry, 1968; Bauerle et al., 1977; Cassidy et al., 1979; Halbout et al., 1979). Morrell et al. (1979) have determined experimentally the linear electro-optic tensor $[r_{ijk}]$ of urea. Further, they have derived theoretical values for the electro-optic coefficients. In the comparison of their experimental results based on the condition of constant mechanical stress ($r_{ijk}{}^{\sigma}$) and theoretical values, which are valid only for constant mechanical strain ($r_{ijk}{}^{\epsilon}$), the elastooptic-electrostrictive contribution ($p_{ijmn}{}^{E}d_{kmn}$) was not taken into account. Moreover, the experimental procedure employed by Morrell et al. (1979) (determination of $r_{231}{}^{\sigma}$) appears to be doubtful. The purpose of this paper is to clarify the role of the electrostrictive effect $[d_{ijk}]$ (def.: $\epsilon_{ij}=d_{kij}E_k$, $[\epsilon_{ij}]$=strain tensor, $[E_k]$=electric field) and to present correct values for electrostrictive and electro-optic effects in urea. The dynamical measurements of electrostrictive and electro-optic effects were performed with the aid of a Michelson interferometer as described recently (Bohaty, 1982). (7 refs.)

77.80B Transitions and Curie point

108884 **Investigation of the phase transition in mixed crystals $Rb_x(NH_4)_{1-x}HSeO_4$ by the pyroelectric method.** H.Pykacz, J.Mroz (Inst. of Phys., Tech. Univ. of Wroclaw, Wroclaw, Poland), Z.Czapla.
Acta Phys. Pol. A (Poland), vol.A64, no.2, p.197-201 (Aug. 1983).
Experimental results on the pyroelectric coefficient are reported for the $Rb_x(NH_4)_{1-x}HSeO_4$ crystals along the ferroelectric *b*-axis with different molar fraction *x*. A non-monotone change of the phase transition temperature depending on the molar fraction of rubidium contents in the crystal has been stated. (11 refs.)

108885 **On the isotopic effect in NH_4HSeO_4.** Z.Czapla, O.Czupinski, L.Sobczyk (Inst. of Chem., Univ. of Wroclaw, Wroclaw, Poland), J.Mroz, H.Pykacz.
Acta Phys. Pol. A (Poland), vol.A64, no.2, p.203-5 (Aug. 1983).
This paper is a comment on the work by W. Bronowska, R. Poprawski and A. Pawlowska published in Acta Phys. Pol. A60, 823 (1981). In the discussed paper the observations of pyroelectric effect and X-ray diffraction pattern have been performed for the polycrystalline samples with 70±10% deuteration degree. There were observed the current peak at 108K, ascribed to low temperature phase transition and a number of peaks above 270K, from which the highest at 299K was ascribed to the para-ferroelectric phase transition. The peaks at higher temperatures were attached to the pyroelectric effect. (9 refs.)

108886 **On the ferroelectric phase transition in $Li_2Ge_7O_{15}$.** H.Terauchi (Dept. of Phys., Kwansei-Gakuin Univ., Hyogo, Japan), S.Iida, Y.Nishihata, M.Wada, A.Sawada, Y.Ishibashi.
J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2313-14 (July 1983).
X-ray scattering experiments on $Li_2Ge_7O_{15}$ were carried out above and below the ferroelectric phase transition temperature $T_c=283.5K$. The space groups are confirmed to be $D_{2h}{}^{14}$-*Pbcn* and $C_{2v}{}^{5}$-*Pbc*2_1 above and below T_c, respectively. The coupling between the ferroelectric displacements of atoms along the *c*-direction and the displacements of atoms along the *a*-direction are important in causing the phase transition.

108887 **A theory of antiferroelectric phase transition in copper formate tetrahydrate $Cu(CHO_2)_2.4H_2O$ crystal. II.** Y.Ishibashi (Synthetic Crystal Res. Lab., Nagoya Univ., Nagoya, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2443-8 (July 1983).
For pt.I see ibid., vol.34, p.888 (1973). The theory of the antiferroelectric transition in copper formate tetrahydrate based upon a dimer model is extended to include the contribution of anharmonicity in interaction of sublattice polarization. For the case of zero applied electric field the temperature behavior of the model system is analyzed with emphases put on the tricritical point, and the peculiarity encountered around the temperature of saturation of the order parameter is pointed out. The applied field vs. temperature phase diagram is discussed.

108888 **Effect of hydrostatic pressure on the phase transitions in monoclinic and tetragonal RbD_2PO_4 crystals.** K.Gesi (JAERI, Ibaraki, Japan), K.Ozawa, T.Osaka, Y.Makita.
J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2538-43 (July 1983).
The effect of hydrostatic pressure was studied for the phase transitions in the two forms of RbD_2PO_4; monoclinic (ferrielectric) and tetragonal (ferroelectric) crystals. In monoclinic crystal, the I-II and II-III transition temperatures monotonically decrease with increasing pressure, and the phase boundaries are represented by a quadratic form of $T_c=T_c{}^0+K_p+\gamma p^2$ with the parameters of $T_c{}^0$, K, and γ being 102.5°C, -50 deg GPa^{-1}, -39 deg GPa^{-2} for the I-II transition and 41.8°C, -24 deg GPa^{-1}, -15 deg GPa^{-2} for the II-III transition, respectively. A pressure-induced phase of IV was newly observed above about 0.7 GPa. The transition to phase IV shows marked first order character. In tetragonal RbD_2PO_4, the ferroelectric Curie temperature monotonically decreases with increasing pressure with the initial slope of -47 deg GPa^{-1}. The slope of the Curie temperature against pressure seems to decrease as pressure increases above about 0.3 GPa. (13 refs.)

108889 **Order-disorder type phase transition in ferroelectric CsD_2PO_4 studied by X-ray structure analysis.** K.Itoh, T.Hagiwara, E.Nakamura (Faculty of Sci., Hiroshima Univ., Hiroshima, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2626-9 (Aug. 1983).
The mechanism of the ferroelectric phase transition of CsD_2PO_4 was investigated by examining the crystal structures determined by X-ray structure analysis at seven different temperatures above and below the transition temperature T_c. The PO_4 group has two equilibrium arrangements in the paraelectric phase while only one of them remains in the ferroelectric phase. The thermal amplitude of the D atom which forms a one-dimensional chain along the ferroelectric *b*-axis reduces drastically at T_c with decreasing temperature. These results are well described on the basis of the mechanism of the order-disorder type phase transition. (12 refs.)

108890 **Static and dynamic dielectric properties on the pressure induced tricritical point of ferroelectric NH_4HSO_4.** A.Tamaki, T.Fujimura (Res. Inst. for Sci. Measurements, Tohoku Univ., Sendair, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2922-30 (Aug. 1983).
The effects of hydrostatic pressure on a ferroelectric compound of NH_4HSO_4 have been investigated with the static, dielectric and pyroelectric measurements. It has been found that the tricritical point of NH_4HSO_4 exists at the temperature of 6.5°C and the pressure of 750 bar. The dielectric critical slowing down at the tricritical point has been observed. The amplitude ratio of the relaxation time above and below the tricritical point has the value of $A/A'=4$, which conforms to the theoretical prediction.

108891 **Phase transition in $\{N(CH_3)_4\}_2MnBr_4$.** K.Gesi (JAERI, Ibaraki, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2931-5 (Aug. 1983).
Single crystals of tetramethylammonium tetrabromomanganate $\{N(CH_3)_4\}_2$-$MnBr_4$ were grown, and the phase transition was studied by dielectric measurements. The crystal shows a phase transition at 3.5°C. The transition temperature increases linearly with increasing hydrostatic pressure with a slope of 0.185 deg MPa^{-1}. Similarity of the lattice parameters, dielectric properties, and pressure coefficient of the transition temperature to those found in $\{N(CH_3)_4\}_2ZnBr_4$ and $\{N(CH_3)_4\}_2CoBr_4$ compounds suggests that there is a common mechanism of the phase transitions in these bromide compounds. (13 refs.)

108892 **Anomalously narrow peak in the dielectric constant of $Cd_2Nb_2O_7$ near the diffuse phase transition.** G.A.Smolenskii, F.M.Salaev, L.S.Kamzina, N.N.Krainik, S.N.Dorogovtsev (A.F. Ioffe Physicotech. Inst., Acad. of Sci., Leningrad, USSR).
JETP Lett. (USA), vol.37, no.6, p.303-6 (20 March 1983). Translation of: *Pis'ma v Zh. Eksp. & Teor. Fiz. (USSR)*, vol.37, no.6, p.257-9 (20 March 1983). [received: Sept. 1983]
An unusually narrow peak is observed in the dielectric constant of the ferroelectric $Cd_2Nb_2O_7$ at 201K, above the broad peak of the diffuse ferroelectric phase transition. Possible causes of this anomaly, observed in this study for the first time, are discussed. (6 refs.)

108893 **Modified phase modulation-only approximation of incommensurate phases in K_2SeO_4-type crystals.** H.Mashiyama (Fachrichtung Experimentalphys., Univ. des Saarlandes, Saarbrucken, Germany).
Phys. Status Solidi b (Germany), vol.118, no.2, p.757-67 (1 Aug. 1983).
The incommensurate-commensurate transition in K_2SeO_4-type crystals is studied on the base of a Landau free energy. The phase modulation-only approximation is modified to take account of the effect of the amplitude modulation partially but in a consistent way. The soliton density decreases continuously with a logarithmic law near the lock-in temperature. It is also shown that the specific heat and the dielectric susceptibility diverge at the transition point. (16 refs.)

108894 **Ammonium dihydrogen phosphate (ADP) impurity effects on phase transition and domain-wall freezing in potassium-ammonium dihydrogen phosphate $[(KDP)_{1-x}(ADP)_x]$ crystals.** B.K.Choi, J.J.Kim (Phys. Dept., Korea Advanced Inst. of Sci. & Technol., Seoul, Korea).
Phys. Rev. B (USA), vol.28, no.3, p.1623-5 (1 Aug. 1983).
Dielectric constants and polarization reversal currents are measured in $(KDP)_{1-x}(ADP)_x$ crystals for $x \lesssim 0.015$ to study the roles of ADP impurities. In this low-concentration limit it seems that the ADP impurities form hard defects responsible for lowering both the ferroelectric transition temperature (T_c) and the domain-wall freezing temperature (T_f). Qualitative discussion is given on the experimental observation of $|dT_f(x)/dx|>|dT_c(x)/dx|$, which causes the range of the plateau anomaly between T_c and T_f to widen rather than narrow in the presence of impurities. (14 refs.)

108895 **Pulsed polarization reversal in gamma-irradiated crystals of triglycine sulfate.** R.M.Pecherskaya, H.Schlemmbach, W.Windsch (Karl Marx Univ., Liepzig, Germany).
Sov. Phys.-Crystallogr. (USA), vol.28, no.2, p.195-7 (March-April 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.2, p.334-8 (March-April 1983). [received: Sept. 1983]
For crystals of triglycine sulfate (TGS) gamma-irradiated with 0.01, 0.05, and 0.1 MR, the authors have investigated how the switching time τ_s in pulsed fields with $E\leq 2$ kV/cm depends on the field strength at temperatures between 288 and 308K. The activation energies for these specimens are calculated. It is shown that in this temperature range the polarization reversal of irradiated TGS crystals is due to at least two different mechanisms. (13 refs.)

108896 **Magnetic studies of phase transformations in SbSI and $Sn_2P_2S_6$ crystals.** S.V.Karbovsky, Yu.V.Masyutka, G.Ya.Pikus.
Ukr. Fiz. Zh. (USSR), vol.28, no.8, p.1242-6 (Aug. 1983). In Russian.
A study of the phase transformation (PT) effect on magnetic susceptibility of ferroelectric semiconductors SbSI and $Sn_2P_2S_6$ made it possible to achieve some additional conclusions on PT mechanism in these compounds. A set of magnetochemical parameters of the crystal under study is established. (10 refs.)

108897 **Ferroelectric domain structure of $PbHPO_4$.** N.Nakatani (Dept. of Appl. Phys., Faculty of Engng., Toyama Univ., Toyama, Japan).
Jpn. J. Appl. Phys. Part 1 (Japan), vol.22, no.6, p.948-51 (June 1983).
Etching methods to delineate the ferroelectric domain structure of $PbHPO_4$ are presented. Geometrical configuration of antiparallel domains bounded by 180° walls were investigated by these methods. The cross sections of domains are generally lenticular or lamellar and stretched along the *a-c* plane. The direction of spontaneous polarization, which lies in the *a-c* plane, was accurately determined by the domain structure revealed by successive etching. It makes an angle of (9.9±0.8)° with the *a*-axis and is almost parallel to the *a**-axis. (21 refs.)

108898 **On the width of charged {110} ferroelectric domain walls in potassium niobate.** Peng Ju Lin (Dept. of Phys., Univ. of Nanking, Nanking, China), L.A.Bursill.
Philos. Mag. A (GB), vol.48, no.2, p.251-63 (Aug. 1983).
High-resolution electron micrographs of {110} domain walls are reported for ferroelectric orthorhombic potassium niobate ($KNbO_3$). Some of the difficulties of interpreting such images are discussed. It is shown that (1) charged 60° and/or 120° domain walls are present, (2) the domain wall structure is incoherent with a spatial periodicity of approximately 800 Å, (3) there are significant ionic displacements localized within ≤15 Å of the walls, (4) there are probably significant changes in electron density over a relatively wider band (~50 Å) and (5) there are small local departures of domain wall orientation from {110}. (11 refs.)

108899 Anomalous domain switching in triglycine sulfate crystals. L.I.Dontsova, N.A.Tikhomirova, L.G.Bulatova, E.S.Popov, A.V.Shil'nikov, L.A.Shuvalov (Engng.-Constructional Inst., Acad. of Sci., Volgograd, USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.2, p.228-30 (March-April 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.2, p.388-91 (March-April 1983). [received: Sept. 1983]
A detailed study is made of the behavior of residual domains in TGS crystals of various thicknesses (10-0.3 mm) at 20-49°C in quasistatic fields of 0.05-9 kV/cm. Investigation of the dependence of the switched charge, simultaneously with revelation of the domain structure for various values of the external constant electric field (at T=const.), has shown that the total switched charge decreases with increase in the external field; this is correlated with the increase in the area of emergent residual domains on the surface of the crystal. 108900 Optical absorption in InP crystals with point radiation defects. E.Yu.Brailovskii, G.N.Eritsyan, N.E.Grigoryan (Erevan Phys. Inst., Erevan, USSR).
Phys. Status Solidi a (Germany), vol.78, no.2, p.K113-15 (16 Aug. 1983).
The results of optical absorption measurements in InP crystals, obtained directly after irradiation are presented. Non-doped n-InP single crystals ($n_0=10^{16}$ cm^{-3}) grown by the Czochralski method were irradiated with 2.5 MeV electrons at a temperature no more than 290K. A strong additional absorption was observed beyond the main absorption edge of the irradiated samples. In the absorption edge region one can observe an increase of the E_0 parameter in the dependence $\alpha=\alpha_0\exp((h\nu-E_g)/E_0)$ from 8 MeV (in the initial crystals) to 25 meV with a dose of $D=1\times10^{18}$ electrons/cm^2. (5 refs.)

108901 Optics of a planar cholesteric layer (inclined incidence). S.M.Osadchii, V.A.Belyakov (All-Union Sci.-Res. Inst. of Physicotech. & Radiotech. Measurements, USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.1, p.66-9 (Jan.-Feb. 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.1, p.123-8 (Jan.-Feb. 1983). [received: Sept. 1983]
The optical characteristics of a planar layer of cholesteric liquid crystal are theoretically investigated for propagation of light at an angle to the cholesteric axis. The characteristic solutions of Maxwell's equations in the cholesteric are analyzed and the optical characteristics corresponding to the first order of selective reflection are calculated on the basis of the two-wave approximation of the dynamic theory of diffraction. The qualitative features are analyzed—in particular, the polarization dependences of the optical properties of cholesterics of propagation of light at an angle to the optic axis. (8 refs.)

108902 Determination of the dispersion and the measurement of the thickness of epitaxial garnet films. Wang Li-xuan (Shanghai Inst. of Metall., Acad. Sinica, China).
Acta Phys. Sin. (China), vol.32, no.4, p.520-4 (April 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)* [received: Sept. 1983]
A technique is proposed for determining the dispersion and measuring the thickness of epitaxial garnet films. Use is made fully of the transmission spectrum obtained by spectrophotometer. When the wavelength is greater than 2 μm so that the absorption and dispersion become negligible, the refractive index at the corresponding wavelength may be calculated from the extrema of the transmittance. According to the condition of interference, the order of interference is calculated and deduced for all interference extrema. The refractive indices of the film at the wavelengths corresponding to the interference extrema may be calculated. Finally the coefficients of Cauchy's dispersion formula are evaluated by the method of least squares, thus the dispersion relation is obtained for this film. Then, in making use of the dispersion relation, the thickness of the film may be calculated. (17 refs.)

108903 Optical properties of a-Si: (Cl, H) films. Liao Xianbo, Yang Xirong, Xu Xuemin, Liu Changling, Kong Guanglin (Inst. of Semiconductors, Acad. Sinica, Beijing, China).
Chin. J. Semicond. (China), vol.4, no.4, p.410-13 (July 1983). In Chinese.
The optical properties of GD a-Si: (Cl, H) films have been measured. The formulae for transmission and reflection coefficients for two layer films with regard to the interference effect are deduced and used to analyse the measured data. The results show that with introduction of chlorine, the optical gap increases and the thermal stability is improved. This can be attributed to the formation of rather strong Si-Cl bonds. (3 refs.)

108904 Optical constants of transition-metal silicides. P.A.Heimann, S.P.Murarka, J.Rosario (Bell Labs., Murray Hill, NJ, USA).
Mater. Lett. (Netherlands), vol.2, no.1, p.31-4 (July 1983).
The authors present values of the indices of refraction and absorption of several transition-metal silicides, measured using an ellipsometer with 632.8 nm light. For cosputtered tantalum silicide, they compare the results of measurements made before and after sintering. For molybdenum silicides, they compare samples which were cosputtered with Si/Mo ratios between 0.47 and 6.5. (8 refs.)

108905 On the real refractive-index change in some *F*-coloured alkali-halide crystals. K.-E.Peiponen, A.Vaittinen, J.Riissanen (Dept. of Math. & Phys., Univ. of Joensuu, Joensuu, Finland).
Nuovo Cimento D (Italy), vol.2D, ser.1, no.4, p.1075-80 (July-Aug. 1983).
The refractive-index change as a function of temperature and frequency will be given for NaCl, KCl and KI crystals which contain *F* colour centres. There exists a frequency value for which the change is independent of the temperature of the sample. (9 refs.)

108906 Argand diagrams and decomposition of the fundamental phianite spectrum into elementary parts. V.I.Vaidanich, N.D.Dovga, E.G.Moroz.
Dopov. Akad. Nauk UkRSR. Ser. A (USSR), no.8, p.45-8 (1983). In Ukrainian.
The Argand diagrams are plotted for the optical functions and effective oscillator parameters are determined for phianite of the $0.9ZrO_2.0.1Y_2O_3$ composition. It is shown that the phianite dispersion curve in the transparent region is determined by the structure of the fundamental spectrum in the vacuum ultraviolet region (6-13 eV). (5 refs.)

108907 Refractive indices of hexagonal ice. R.Onaka, T.Kawamura (Inst. of Appl. Phys., Univ. of Tsukuba, Ibaraki, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2947-53 (Aug. 1983).
The refractive indices of hexagonal ice (Ih) are studied in the wavelength range down to 2537 A, and the wavelength dispersion curves are obtained. From the curves the energy of the representative oscillator is found to be 12.3 eV both for ordinary and extraordinary rays. The temperature dependences of the refractive indices are also studied. It is found that they are mainly due to the thermal dilation of the lattice, and the change in the electronic polarizability is little. This suggests that ice is a molecular crystal in a fairly good approximation. (14 refs.)

108908 Dispersion of optical constants of amorphous $Si_{1-x}Ge_x(H)$ films beyond their absorption edges. K.C.Kao, R.D.McLeod, C.H.Leung, H.C.Card (Dept. of Electrical Engng., Univ. of Manitoba, Winnipeg, Manitoba, Canada), H.Watanabe.
J. Phys. D (GB), vol.16, no.9, p.1801-11 (14 Sept. 1983).
Optical constants of amorphous hydrogenated $Si_{1-x}Ge_x(H)$ films fabricated by radio frequency sputtering have been measured for $0\leq x\leq1$ at wavelengths from 0.35 μm to 2.65 μm using both spectrally-resolved ellipsometry and spectrophotometry. The data include measurements on the refractive index in the high absorption region. The results show that the refractive index, the extinction coefficient, the loss factor and the optical band gap vary approximately linearly with x (the content of Ge). The refractive index and the extinction coefficient are dispersive and exhibit two peaks in their spectra, one above and the other below the optical absorption edge. The first peak is attributed to interband transitions and the second peak to transitions involving localised states in the mobility gap. (34 refs.)

108909 Some optical properties of materials measured at 1.3 μm. N.C.Fernelius, R.J.Harris, D.B.O'Quinn, M.E.Gangl, D.V.Dempsey (Univ. of Dayton Res. Inst., Dayton, OH, USA), W.L.Knecht.
Opt. Eng. (USA), vol.22, no.4, p.411-18 (July-Aug. 1983).
This work surveys the properties of materials at 1.3 μm. The interest in this wavelength has been generated by the development of second generation optical fibers and by the development of the iodine (I*) laser, which operates at 1.315 μm. Most of the data reported were taken by Nd:YAG lasers modified to operate at 1.319 μm. Spectral scans of some less common materials are presented. The effective optical absorption coefficient β_{eff} measured by laser rate calorimetry is given for all materials. The thermo-optic coefficient $\partial n/\partial T$ at 1.3 μm is given for a number of materials. If 1.3 μm results are lacking, values at 1.15 μm are given. Among the lower absorbing materials are KCl, LiF, NaCl, CaF_2, SiO_2, YLF ($LiYF_4$), sapphire (Al_2O_3), MgF_2, BaF_2, and Q-98 phosphate glass. Results on a number of Schott infrared and laser glasses are given, including LG-670, LG-660, LG-750, LG-810, LG-760, LG-680, IRG-7, IRG-9, IRG-3, and IRG-N6. Results are given also on ZnS (normal and water clear), YAG ($Y_3Al_5O_{12}$), ZrO_2, SrF_2, ZnSe, MgO, and CdTe. Some other glasses studied were hafnium fluoride glass, As_2S_3, CORTRAN 9753 and 9754, and Barr and Stroud calcium aluminate glasses BS 39B and BS 37A. The ten lowest absorbing materials had effective optical absorption coefficients β_{eff} between 0.13 and 0.5×10^{-3} cm^{-1}. The lowest $\partial/\partial T$ value measured was -0.06×10^{-5}/°C on Schott LG-660 alkali-Zn-silicate glass. (33 refs.)

108910 The influence of the structure of different arsenic chalcogenide glasses on refractive index and dispersion. W.Burckhardt, A.Feltz (Sektion Chem., Friedrich-Schiller-Univ. Jena, Jena, Germany).
Phys. Status Solidi b (Germany), vol.118, no.2, p.653-60 (1 Aug. 1983).
The refractive index dispersion of different arsenic chalcogenide glasses is analyzed by the use of a two-term Sellmeier dispersion formula. In a region from 3 μm up to the beginning of the absorption edge the wavelength dependence of the refractive index can be described by a single oscillator model. At wavelengths λ_j, determined by $\lambda_{1j}/\lambda_j=$const, the molar refraction of the different glasses is a linear function of $n_{eff}\lambda_1^2$. In representations $R_M=R_M\ (n_{eff})$ and $R_M=R_M\ (\lambda_1^2)$ the influence of the structure of the different glasses is clearly illustrated. For the glass $AsSe_3$ a special short-range order is indicated. (18 refs.)

108911 On the reflectivity for oblique incidence of the uniaxial antiferromagnetic crystals FeF_2, CoF_2, and MnF_2. A.Lehmeyer (Phys. Inst., Westfalischen Wilhelms-Univ., Munster, Germany), L.Merten, K.M.Haussler.
Phys. Status Solidi b (Germany), vol.118, no.2, p.675-9 (1 Aug. 1983).
The combining the dispersion relations of the refractive index and the boundary conditions in the surface the formulae of reflectivity of the antiferromagnetic crystals FeF_2, CoF_2, and MnF_2 can be derived for oblique incidence. This is performed for two important orientations of the surface namely for the surface perpendicular to the optical axis and for a surface which contains the optical axis. The results are six different formulae of reflectivity for oblique incidence. (3 refs.)

108912 Intraband absorption due to alloy scattering in lead chalcogenide semiconductors. K.Siedranski, J.Szatkowski (Inst. of Phys., Tech. Univ. of Wroclaw, Wroclaw, Poland).
Phys. Status Solidi b (Germany), vol.118, no.2, p.871-9 (1 Aug. 1983).
Free carrier absorption allowed by the chemical disorder is calculated for lead chalcogenide mixed semiconductors. It is found that the absorption due to the intervalley transitions may be greater than that due to the intervalley transitions. (13 refs.)

108913 The influence of dipole molecules adsorption on the fine-porous membranes polarizability. R.Alexandrescu, N.Comaniciu, I.N.Mihailescu, I.Morjan (Central Inst. of Phys., Bucharest, Rumania), V.A.Kravcenko, Yu.N.Petrov, V.I.Kuznetsov.
Rev. Roum. Phys. (Rumania), vol.28, no.4, p.339-42 (1983).
The influence of adsorbed dipolar molecules (H_2O, CH_3I, C_5H_5N, C_3H_6O, CH_3CN, $C_6H_5NO_2$) on the optical thickness of fine-porous membranes made of mica and polymer film was studied. A rather rigorous orientation of the adsorbed molecules was evidenced. (4 refs.)

108914 Dielectric function of SmS. I. Optical transitions. G.Guntherodt, J.L.Freeouf, F.Holtzberg (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA).
Solid State Commun. (USA), vol.47, no.9, p.677-80 (Sept. 1983).
The dielectric response function of SmS and SmAs has been determined via a Kramers-Kronig transformation of the room temperature reflectivity in the range from 10^{-2} eV to 22 eV. In SmS the assignment of optical transitions, including those from the (S) 3s core level, has been corroborated by the corresponding ones of SmAs. Reductions of the 4f binding energy are revealed in optical $f \rightarrow d$ transitions as compared to X-ray photoemission data. (17 refs.)

108915 Dielectric function of SmS. II. Infrared response: LO(Γ) phonon softening. B.Hillebrands, G.Guntherodt (II Phys. Inst., Univ. Koln, Koln, Germany).
Solid State Commun. (USA), vol.47, no.9, p.681-2 (Sept. 1983).
For pt.I see ibid., vol.47, no.9, p.677 (1983). The zone-center longitudinal optical phonon of semiconductor SmS shows a 10% softening with respect to that of EuS. This result confirms the lattice-dynamical model prediction and provides first experimental evidence for the existence of an anomalous dipolar charge deformability of the Sm^{2+} ion in SmS. (8 refs.)

108916 Analysis of conditions for additional minimum formation in the linear-cross splitting region in exciton reflection spectra. P.S.Kosobutskii.
Ukr. Fiz. Zh. (USSR), vol.28, no.7, p.1090-1 (July 1983). In Russian.
Investigates the conditions for the appearance of the anomalous slope for the reflectivity curve of a crystal surface without an exciton layer. An expression is obtained which permits one to determine the layer thickness using the energy position of the additional maximum on the reflectivity curve. (3 refs.) *V.G.P.*

108917 Influence of glass structure on refractive index and dispersion. W.Burckhardt (Friedrich-Schiller-Univ. Jena, Jena, Germany).
Wiss. Z. Friedrich-Schiller-Univ. Jena, Math. Naturwiss. Reihe (Germany), vol.32, no.2-3, p.205-13 (1983). In German. (Otto-Schott-Colloquium on the State of Optical Glass Research 1982, Jena, Germany, 1982).
The refractive indices of 20 chalcogenide glasses were measured in the range of 1-12 μm according to the principle of minimum deviation. The wavelength dependence of the refractive index was mathematically modelled with a 2-term dispersion formula. For comparison of the different glasses it is necessary to normalize on a constant number of particles. In the range from 3-4 μm up to the energy rich limit of the transparent region the wavelength dependence of the refractive index can be described by a single-oscillator-model. At wavelengths, which are determined by $\lambda_1/\lambda=$const., glasses with the same structure and having a continuous change of structure are situated in the representations $R_M/\Sigma x_i Z_i=f(\lambda_1^2)$ and $-dR_M/d\lambda/\Sigma x_i Z_i=f(\lambda_1)$ on a straight line. A structural influence on the refractive index and dispersion is clearly reflected. (7 refs.)

(inc. stress birefringence, flow birefringence, etc)

108918 Temperature dependences of optical birefringence and dielectric constant of $[N(CH_3)_4]_2ZnCl_4$ crystals. O.G.Vlokh, A.V.Kityk, I.V.Kityk, I.I.Polovinko.
Ukr. Fiz. Zh. (USSR), vol.28, no.7, p.1099-100 (July 1983). In Russian.
Investigates the temperature dependencies of optical birefringence and the real part of dielectric constant in $[C(CH_3)_4]_2ZnCl_4$ crystals. It is established that anomalies exist in successive phase transitions from paraelectric to commensurate and ferroelectric to ferroelastic phases. In the incommensurate phase, the birefringence is described by $\delta(\Delta n)\sim(T-T_i)^\gamma$ with critical indices $\gamma=0.53$; 0.75;| for a-, b- and c-cleavages respectively. (11 refs.) *V.G.P.*

108919 Flow birefringence and angles of its orientation in solutions of poly-α-methyl styrene. L.N.Andreeva, E.V.Belyaeva, A.A.Boikov, P.N.Lavrenko, V.N.Tsvetkov.
Vysokomol. Soedin. Ser. A (USSR), vol.25, no.8, p.1631-7 (Aug. 1983). In Russian. English translation in: *Polym. Sci. USSR (GB)*
The flow birefringence of solutions of narrow fractions of poly-α-methyl styrene in tetrabromomethane has been studied. The characteristic angles of orientation are determined. From the values of the characteristic angle of orientation $[\chi/g]$, intrinsic viscosity $[\eta]$ and MM the experimental value of G coefficient was calculated for the theoretical relation: $[\chi/g]=GM[\eta]\eta_0/RT$, where M is the MM value, η_0 is the viscosity of the solvent. The average G value is equal to 0.2. This value for flexible poly-α-methyl styrene (the length of statistical Kuhn segment is equal to 20 Å) twofold exceeds G values predicted by existing theories. (26 refs.)

108920 On the conformation of aromatic polyamide in organic solvent and concentrated sulfuric acid according the data of flow birefringence. I.N.Shtennikova, T.I.Garmonova.
Vysokomol. Soedin. Ser. A (USSR), vol.25, no.8, p.1643-8 (Aug. 1983). In Russian. English translation in: *Polym. Sci. USSR (GB)*
Flow birefringence $[n]/[\eta]$ and orientation angles $[\chi/g]$ of polyamidebenzimidazol molecules in DMAA have been studied in the wide range of molecular masses: $(0.2\text{-}7.5).10^4$. The optical and conformational properties of polymer molecules in DMAA and concentrated sulfuric acid are compared. The conformation of this polymer (kinetically rigid coil) is shown to be practically the same in both solvents. This fact points out the practical absence of the significant role of protonization of molecules during the process of formation of conformations of aromatic polyamides macromolecule in sulfuric acid. 78.20H Piezo-, elasto- and acousto-optical effects

108921 Ultrasonic modulation of persistent spectral holes in crystals. H.Lengfellner, T.R.Gosnell, R.W.Tkach, A.J.Sievers (Lab. of Atomic & Solid State Phys., Cornell Univ., Ithaca, NY, USA).
Appl. Phys. Lett. (USA), vol.43, no.5, p.437-9 (1 Sept. 1983).
Persistent IR spectral holes in $KI:ReO_4^-$ and in $RbI:ReO_4^-$ crystals have been both modulated and erased with 10-MHz ultrasound. This mechanical modulation of the hole depth leads to a new phase-insensitive optical detector for ultrasonic waves in solids. (11 refs.)

108922 Acoustooptical interaction of bounded wave beams. V.I.Balakshii, H.A.Upasena (Dept. of Oscillation Phys., Moscow Univ., Moscow, USSR).
Moscow Univ. Phys. Bull. (USA), vol.37, no.5, p.81-7 (1982). Translation of: *Vestn. Mosk. Univ. Ser. 3 (USSR)*, vol.37, no.5, p.71-6 (1982).
Two limiting cases of the acoustooptical interaction of bounded light and ultrasound beams are considered: diffraction of the light beam at a monochromatic acoustic wave and diffraction of a plane light wave at an acoustic wave train. It is shown that, even with the same dimensions of the interaction region, there are significant differences in the structure of the diffracted-light field and in the character of dependence of the diffraction efficiency of the parameters of the acoustic cell. (5 refs.)

108923 Bragg acoustooptical interaction in crystal media. A.S.Zadorin (Tomsk Inst. of Automatic Control Systems & Radio Electronics, Tomsk, USSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.12, p.1055-61 (Dec. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.12, p.1491-8 (Dec. 1982). [received: Sept. 1983]
Solves a self-consistent problem for Bragg diffraction of plane light waves from elastic oscillations in crystals of any symmetry class. General expressions have been obtained for the amplitude and intensity, and for the quality factor M_2 of the medium. The effect of deviation of the light and acoustic rays from

the wave normals on the efficiency and bandwidth of acoustooptical interaction is determined. (9 refs.)

78.20J Electro-optical effects

108924 Electrooptic diffraction in polydomain barium-sodium niobate crystals. A.L.Aleksandrovskii, A.I.Nagaev (Dept. of Phys., Moscow State Univ., Moscow, USSR).
Phys. Status Solidi a (Germany), vol.78, no.2, p.431-8 (16 Aug. 1983).
Two types of field-driven light diffraction in barium-sodium niobate crystals (BSN) with lamellar domain structure are studied theoretically and experimentally. The relation of these effects to the physical properties of inhomogeneous ferroelectric crystals is investigated. (18 refs.)

108925 Electrooptic diffraction of light by antiparallel ferroelectric domains in $Ba_2NaNb_5O_{15}$ crystals. A.L.Aleksandrovskii, A.I.Nagaev (M.V. Lomonosov State Univ., Moscow, USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.1, p.53-7 (Jan.-Feb. 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.1, p.102-8 (Jan.-Feb. 1983). [received: Sept. 1983]
The authors analyzes isotropic and anisotropic electrooptical diffraction of light by a layered domain structure. They study the field and temperature dependences of the diffracted-light intensity. (15 refs.)

108926 Electric-field-induced chirality of octahedral $Cr^{3+}6H_2O$ complexes in alum. H.J.Weber (Inst. of Crystallography, Cologne Univ., Cologne, Germany).
Sov. Phys.-Crystallogr. (USA), vol.28, no.2, p.187-91 (March-April 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.2, p.320-7 (March-April 1983). [received: Sept. 1983]
The author has measured the optical rotation and circular dichroism induced by an electric field in potash, cesium, and methyl ammonium aluminum alums with chromium as impurity between 400 and 700 nm. In this optical region Cr^{3+} has two absorption bands, but the electrogyration effect appears in only one of them—the permitted magnetic dipole band. The induced rotatory power has opposite signs in α and β alums and its absolute magnitude increases with fall of temperature in all the crystals. It is established that the cause of the effect is latent chirality of the H_2O cavity surrounding the central Cr^{3+} ions. The sign of the effect is governed by the orientation of the H_2O octahedra within the unit cell. (21 refs.)

108927 The benitoites $KMgP_3O_9$, $KZnP_3O_9$ and $KCaP_3O_9$: crystal growth, electrooptical and electrostrictive properties. L.Bohaty, J.Liebertz (Inst. fur Kristallographie, Univ. zu Koln, Koln, Germany).
Z. Kristallogr. (Germany), vol.163, no.3-4, p.251-4 (1983). In German.
Single crystals of the isotypic compounds $KMgP_3O_9$, $KZnP_3O_9$, and $KCaP_3O_9$ (benitoite-type) with dimensions up to 35 mm have been grown from the melt. Because of the high viscosity of the melts a special growth method was necessary. The linear electrooptical tensor $[r_{ijk}]$ and the tensor of the linear electrostriction $[d_{ijk}]$ have been determined: $r_{222}=0.17(2)$, $d_{222}=0.51(2)$ ($KMgP_3O_9$); $r_{222}=0.13(3)$, $d_{222}=0.32(3)$ ($KZnP_3O_9$); $r_{222}=-0.23(3)$, $d_{222}=1.83(5)$ ($KCaP_3O_9$) (unit: 10^{-12} m/V, $T=295K$, $\lambda=633$ nm). 78.20L Magneto-optical effects

108928 Frequency dispersion and angular dependence of an equatorial change in the intensity of light transmitted by iron and cobalt films. A.V.Druzhinin, I.D.Lobov, V.M.Maevskii, G.A.Bolotin (Inst. of Metal Phys., Ural Sci. Centre, Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.58-65 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A theory is proposed of the linear (in respect of the magnetization) change in the intensity of light polarized in the plane of incidence as a result of its passage through a three-layer system comprising an equatorially magnetized ferromagnetic film between two nonmagnetic layers. It is shown that this effect appears when the conditions for internal reflection are different for the upper and lower boundaries of the magnetic film. A report is given of a determination of the dependence of this effect on the angle of incidence of light on iron and cobalt films and of a study of its frequency dispersion in the near infrared and visible parts of the spectrum (1-3.1 eV). The results of the measurements are used to calculate the dispersion of the nondiagonal component of the permittivity tensor of an iron film. (14 refs.) *A.T.*

108929 Magneto-optical properties of metallic ferromagnetic materials. K.H.J.Buschow, P.G.van Engen, R.Jongebreur (Philips Res. Labs., Eindhoven, Netherlands).
J. Magn. & Magn. Mater. (Netherlands), vol.38, no.1, p.1-22 (Aug. 1983).
The authors have studied the magneto-optical Kerr rotation in more than 200 metallic systems comprising alloys as well as intermetallic compounds of 3d transition metals. For all these materials the crystal structure, the lattice constants, the room temperature magnetization and the room temperature Kerr rotation at two different wavelengths are specified. For several series of ternary compounds, comprising Heusler alloys Ni_2In-type compounds and $Cr_{23}C_6$ type compounds, they determined the saturation moment at 4.2K. For a number of representative alloys or compounds a study was also made of the wavelength dependence of the complex polar Kerr effect. The values of the Kerr rotation obtained at 633 nm were compared with the corresponding values of the measured magnetization. Systematic trends were observed and have been used to classify metallic systems into systems where the Kerr rotation does not reach values much in excess of 1° and systems where higher values are likely to be found. (23 refs.)

108930 Magneto-optical investigations of a novel superlattice: HgTe-CdTe. Y.Guldner, G.Bastard, J.P.Vieren, M.Voos (Groupe de Phys. des Solides, Ecole Normale Superieure, Paris, France), J.P.Faurie, A.Million.
Phys. Rev. Lett. (USA), vol.51, no.10, p.907-10 (5 Sept. 1983).
Far-infrared magnetoabsorption experiments done in a HgTe-CdTe superlattice are presented. From the results, which are interpreted in terms of interband transitions from valence to conduction subbands, the superlattice band structure has been deduced. These investigations show, in particular, that this superlattice is a quasi zero-energy-gap semiconductor, and yield the first determination of the offset between the HgTe and CdTe valence bands. (8 refs.)

108931 Effect of a finite semiconductor substrate on the Faraday rotation and ellipticity in a metal-oxide-semiconductor system. R.F.O'Connell, G.Wallace (Dept. of Phys. & Astron., Louisiana State Univ., Baton Rouge, LA, USA).
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.41-46 (1983).
Studies the effect of a finite semiconductor substrate on the Faraday rotation and ellipticity in a metal-oxide-semiconductor system. The authors find that the multiple reflections within the semiconductor substrate can give an enhancement by factors of up to 2.5 over the case where the semiconductor is considered semi-infinite. In addition, the ellipticity is markedly changed and, in particular, null values may be obtained in contrast with the results obtained without multiple reflections within the semiconductor. (4 refs.)

78.30 INFRARED AND RAMAN SPECTRA AND SCATTERING

108932 Mechanism of the 'spillover' of Raman spectral lines and the change of their intensities in α-$LiLO_3$ single crystal under the action of a DC field. Yang Hua-guang, Li Chen-xi, Xu Zheng-yi (Inst. of Phys., Acad. Sinica, Peking, China).
Acta Phys. Sin. (China), vol.32, no.4, p.539-43 (April 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)* [received: Sept. 1983]
The 'spillover' of the Raman spectral lines and the change of their intensities were observed in α-$LiIO_3$ single crystal under the action of a DC field. They are due to the fluctuation of the polarizability tensor and the Raman tensor of α-$LiIO_3$ single crystal during the transportation of ions. The former induces the $o \rightleftharpoons e$ scattering. Subsequently, if this $o \rightleftharpoons e$ scattering light acts as an incident beam to produce Raman scattering, the phenomena mentioned above could occur. The latter brings about the phenomena directly. The former mechanism is predominant. (6 refs.)

108933 One-magnon Raman scattering in $RFeO_3$—magnetic anisotropy and magnon softening. N.Koshizuka, K.Hayashi (Electrotech. Lab., Ibaraki, Japan).
Bull. Electrotech. Lab. (Japan), vol.47, no.4, p.250-60 (1983). In Japanese.
One-magnon Raman scattering spectra of various rare-earth orthoferrites were observed to obtain the magnetic in-plane and out-of-plane anisotropy energy of these systems. Furthermore, detailed temperature dependences of the scattering spectra were measured to study magnon-softening phenomena in $ErFeO_3$, $SmFeO_3$, $Er_{0.7}Sm_{0.3}FeO_3$ and $DyFeO_3$. It has been made clear that the softening behavior is different between rotational- and abrupt-type spin-reorientation systems because of different anisotropy energy terms which contribute to the spin-orientation transitions. From temperature dependences of magnon frequencies in $YFeO_3$ with no spin-reorientation, thermal behaviors of single-ion anisotropy energy of Fe^{3+} ions were obtained. It turns out that the conventional two-sublattice model of $RFeO_3$ is not a good approximation to understand the softening behaviors near the spin-reorientation transition temperatures. It is considered necessary to take into account the role of the Fe^{3+}-R^{3+} exchange interactions in developing the spin-wave mode theory of $RFeO_3$. (28 refs.)

108934 Far-infrared powder spectrum of $(N(CH_3)_3D)(I)(TCNQ)$. J.E.Eldridge, N.Fortier, F.E.Bates (Dept. of Phys., Univ. of British Columbia, Vancouver, BC, Canada), J.S.Miller.
Can. J. Phys. (Canada), vol.61, no.9, p.1271-7 (Sept. 1983).
Presents the powder absorption spectrum of (TMA)(I)(TCNQ) in the far-infrared as a function of temperature. Below 160K new absorption features appear and others increase in intensity. This behaviour supports the electron- and neutron-diffraction evidence of a distortion on the TCNQ chains below the first phase-transition temperature. Effects due to the second phase transition at 89K are also observed. The results of a group-theoretical analysis are presented. These show that totally-symmetric internal modes a_g are to be expected in the infrared spectra of this compound even in the undistorted phase. (35 refs.)

108935 Surface-enhanced Raman scattering of polymethine dyes on silver colloidal particles. K.Kneipp, G.Hinzmann, D.Fassler (Chem. Dept., Friedrich-Schiller-Univ., Jena, Germany).
Chem. Phys. Lett. (Netherlands), vol.99, no.5-6, p.503-6 (19 Aug. 1983).
SERS was observed from adsorbed cationic cyanine and neutral merocyanine dyes, whereas the tested oxonol dye did not show any adsorption on the silver colloids. A comparison between Raman scattering of the first three representatives of the homologous series of one dye and Raman experiments performed on the same dyes in solution confirms the existence of SERS. (9 refs.)

108936 High-pressure Raman study of liquid and molecular crystal at room temperature. Carbon disulphide. H.Shimizu, T.Ohnishi (Dept. of Electrical Engng., Gifu Univ., Gifu, Japan).

Chem. Phys. Lett. (Netherlands), vol.99, no.5-6, p.507-11 (19 Aug. 1983).

The Raman spectra of liquid and crystalline CS_2 were measured at pressures up to 45 kbar and room temperature. The pressure dependences of the internal modes (ν_1 and $2\nu_2$) and the four librational lattice modes are reported. Comparison of the spectrum of high-pressure crystals at 300K with that of the low-temperature crystals at 1 bar indicates that the structure of each crystal resembles mutually. (14 refs.)

108937 A new assignment of the Raman spectrum of tetracyanoethylene anion dimer, $(TCNE^-)_2$. K.H.Michaelian (Energy, Mines & Resources Canada, CANMET/CRL, Sherwood Park, Alberta, Canada), K.E.Rieckhoff, E.M.Voigt, S.Matsuzaki, T.Mitsuishi, K.Toyoda.

Chem. Phys. Lett. (Netherlands), vol.99, no.5-6, p.512-16 (19 Aug. 1983).

Recently published resonance Raman data for $(TCNE^-)_2$ ethanol, are reassigned in light of earlier results for neutral or complexed TCNE and for $(TCNE^-)_2$ in 2-methyltetrahydrofuran. Counterion and solvent influence are discussed. (21 refs.)

108938 Quantum beating of vibrational factor group components in molecular solids. S.Velsko, J.Trout, R.M.Hochstrasser (Dept. of Chem., Univ. of Pennsylvania, Philadelphia, PA, USA).

J. Chem. Phys. (USA), vol.79, no.5, p.2114-20 (1 Sept. 1983).

The authors report the first observation of coherent Raman induced quantum beats from exciton states in molecular crystals. The paper describes the relevant crystal optics and phasematching conditions needed to ensure coherent excitation of more than one Raman transition in a anisotropic solid. The study of the 991 cm^{-1} mode of C_6H_6 at 1.6K has allowed the identification of two nearby (0.6 cm^{-1}) factor group components and their lifetimes. The larger damping of the weaker $A_g \rightarrow B_{2g}$ transition suggests that intraband scattering is operative. (20 refs.)

108939 Spectroscopic studies of molecular interactions of oxygen-16 and oxygen-18 in the high-density ϵ-phase. B.I.Swanson, S.F.Agnew, L.H.Jones, R.L.Mills, D.Schiferl (Los Alamos Nat. Lab., Univ. of California, Los Alamos, NM, USA).

J. Phys. Chem. (USA), vol.87, no.14, p.2463-5 (7 July 1983).

Infrared and Raman spectra were obtained for solid $^{16}O_2$ and $^{18}O_2$ as a function of pressure, using diamond-anvil cells. When both isotopes are compressed into the ϵ-phase near 9.9 GPa, a strong infrared band appears in the O-O stretch region, 48 cm^{-1} lower than the Raman-active O-O stretch. As pressure is increased, the infrared absorption shifts to lower frequency, eventually splitting into two bands at 16.0 GPa. Two combination modes, which also shift to lower frequency with increasing pressure, are observed in the 3000-cm^{-1} region of the IR spectra. The ϵ-phase also exhibits a second Raman mode around 130 cm^{-1}, which shifts to higher frequency with pressure. The results indicate that the O-O bond weakens at the expense of forming O_2-O_2 intermolecular interactions in the ε-phase. The spectroscopic results show that the structure of the ϵ-phase is centric with, most likely, four molecules per primitive cell. (16 refs.)

108940 Surface-enhanced resonance Raman spectroscopy of adsorbates on semiconductor electrode surfaces: tris(bipyridine)ruthenium(II) adsorbed on silver-modified n-GaAs (100). R.P.Van Duyne, J.P.Haushalter (Dept. of Chem., Northwestern Univ., Evanston, IL, USA).

J. Phys. Chem. (USA), vol.87, no.16, p.2999-3003 (4 Aug. 1983).

The first observations of surface-enhanced resonance Raman scattering (SERRS) from tris(bipyridine)ruthenium(II), $Ru(bpy)_3{}^{2+}$, at monolayer (or less) coverage on n-GaAs(100) semiconductor (SC) electrodes modified by the electrodeposition of ca. 100 monolayers of Ag metal are reported. In addition to the SERRS studies, the photoelectrochemical and surface microstructural properties of $Ag/GaAs/Ru(bpy)_3{}^{2+}$ electrodes were studied by cyclic voltammetry (CV) and scanning electron microscopy (SEM). (41 refs.)

108941 Surface-enhanced Raman spectroscopy of platinum. II. Enhanced light scattering of chlorine adsorbed on platinum. B.H.Loo (Dept. of Chem., Univ. of Alabama, AL, USA).

J. Phys. Chem. (USA), vol.87, no.16, p.3003-7 (4 Aug. 1983).

For pt.I see Solid State Commun., vol.43, p.349 (1982). Surface-enhanced Raman scattering has been observed from electrogenerated chorine adsorbed on a platinum electrode with 488-, 496.5-, and 514.5-mm Ar^+ and 647.1- and 676.4-nm Kr^+ laser excitation wavelengths. Two vibrational features at 509 and 541 cm^{-1} with an approximate intensity ratio of 1:2 are assigned to the surface vibrations of bridged and linear chlorine on platinum, respectively. This is the first report of a surface vibrational spectrum of molecular chlorine adsorbed on a metal surface. (37 refs.)

108942 Raman scattering and fundamental absorption in red-HgI_2 under hydrostatic pressure. N.Kuroda, T.Iwabuchi, Y.Nishina (Res. Inst. for Iron, Steel & Other Metals, Tohoku Univ., Sendai, Japan).

J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2419-27 (July 1983).

The Raman scattering and optical absorption spectra have been measured under hydrostatic pressure up to 1.67 GPa in the layer compound red-HgI_2. The Raman spectrum shows that the bending force of HgI_4 tetrahedra is too weak for a layer to vibrate rigidly in the so-called rigid-layer mode. The bending force increases rapidly with pressure, whereas the van der Waals force remains unchanged. These characteristics originate from the fact that the bond ionicity is extremely high and sensitive to pressure. The fundamental absorption edges exhibit red shifts, giving an evidence that the ionicity decreases with pressure. Anisotropy in elastic constants is also discussed in relation to the nature of chemical bondings. (25 refs.)

108943 Simple theory for surface-plasmon-polariton resonance on sinusoidal metal surface: application to SERS. M.Yamashita, M.Tsuji (Dept. of Appl. Sci., Kyushu Univ., Fukuoka, Japan).

J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2462-71 (July 1983).

The field enhancement for a *p*-polarized incident light near a sinusoidal grating surface arising from surface-plasmon-polariton excitation is studied by an improved first-order perturbation theory in which the importance of the back-scattering terms is taken into account. The dependences of the reflectivity and the enhancement factor on the amplitude of the grating are discussed. The maximum enhancement factor and the most suitable grating amplitude are calculated as functions of the frequency of the incident light for various grating periodicities. Under certain circumstances, the field enhancement may achieve above 10^3 for Ag gratings near 1.3 eV of the incident-light frequency. It means 10^6 times enhancement of the Raman scattering (SERS) of molecules adsorbed on the metallic grating surface. (35 refs.)

108944 Complete first-order Raman spectra of the pyrite structure compounds FeS_2, MnS_2 and SiP_2. H.Vogt, T.Chattopadhyay, H.J.Stolz (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany).

J. Phys. & Chem. Solids (GB), vol.44, no.9, p.869-73 (1983).

The first-order Raman spectra of FeS_2, MnS_2 and SiP_2 are measured at room temperature. The frequencies of all Raman-active phonons are obtained. The authors describe the displacement patterns and discuss the extent to which the concept of a molecular crystal can be applied. (19 refs.)

108945 Spectroscopic study of thermal cure of R-2M polymer binder. N.I.Sushko, N.I.Makarevich.

J. Appl. Spectrosc. (USA), vol.37, no.5, p.1265-9 (Nov. 1982). Translation of *Zh. Prikl. Spektrosk. (USSR)*, vol.37, no.5, p.776-80 (Nov. 1982). [received Sept. 1983]

Glass-fiber reinforced plastics are composite materials based on glass-fiber reinforced fillers and cured polymer binders. The role of a binder in the glass-fiber reinforced plastics consists mainly in uniting separate glass fibers into a monolithic material. The binder also imparts special physicochemical properties to the glass-fiber reinforced plastic. Thermoreactive (polyester epoxide, phenol-formaldehyde, organosilicon) and also thermoplastic polymers (polyamides, polyolefins, polystyrene) are used as polymer binders. In Soviet industry, phenol-formaldehyde R-2M resin is widely used for the preparation of glass-fiber molding materials. Glass-fiber materials AG-4V, AG-4S, DSV and others are prepared from it. To clarify the characteristic features of the thermal cure of the R-2M binder, the authors studied the changes in the IR absorption spectra of the R-2M binder and BP-4 adhesive during heat treatment. (5 refs.)

108946 Study of acid properties of ferrierite surface by IR spectroscopy. V.S.Komarov, L.N.Malashevich, N.A.Akulich, M.F.Savchits.

J. Appl. Spectrosc. (USA), vol.37, no.5, p.1269-71 (Nov. 1982). Translation of: *Zh. Prikl. Spektrosk. (USSR)*, vol.37, no.5, p.780-4 (Nov. 1982) [received: Sept. 1983]

There are several data in the literature on the study of physicochemical adsorptional, and catalytic properties of synthetic zeolite ferrierite with a high silicon content, with the ratio $SiO_2/Al_2O_3=10$, and a superhigh-silicon zeolite with ratio $SiO_2/Al_2O_3=$ 20-30. The study of the catalytic properties of this zeolite showed that it has a fairly high activity in the cracking reaction of n-hydrocarbons. It was therefore interesting to study the nature of the acid centers on the ferrierite surface, closely related to its catalytic activity. (14 refs.)

108947 Optical properties of donor electrons in semimagnetic semiconductors. T.Dietl (Inst. of Phys., Polish Acad. of Sci., Warsaw, Poland).

J. Magn. & Magn. Mater. (Netherlands), vol.38, no.1, p.34-44 (Aug. 1983).

The cross section of the spin-flip Raman scattering and the absorption coefficient of the electric-dipole spin-resonance of donor electrons in $Cd_{1-x}Mn_xSe$ are calculated. The exchange induced spin-splitting of a donor level is described taking into account three sources of a local magnetization; external magnetic field, thermodynamical fluctuations of magnetization and molecular field of the donor electron (bound magnetic polaron). The theory takes into account the selection rules appropriate for the hexagonal CdMnSe. The role played by fluctuations of composition is considered. It is suggested that a spin-flip line is inhomogeneously broadened by thermodynamical fluctuations of magnetization and additionally, in high fields, by fluctuations of the composition. (26 refs.)

108948 Enhanced Raman scattering from silicon microstructures. D.V.Murphy, S.R.J.Brueck (Lincoln Lab., MIT, Lexington, MA, USA).

Opt. Lett. (USA), vol.8, no.9, p.494-6 (Sept. 1983).

Electromagnetic-structure-resonance enhancement of scattering from Si phonon modes is reported for a number of submicrometer structures. Enhancements of $\gtrsim 100$ over the Raman intensity from bulk Si are observed for ~ 0.1-μm-diameter Si spheres. An analytic calculation of the Raman intensity for this geometry is in good qualitative agreement with the experiment and demonstrates that the enhancement arises from the coupling of both the incident and the scattered fields with the low-order-structure resonances in this high-index dielectric. (13 refs.)

108949 A Raman study of compositional disorder in defect chalcopyrites. C.Razzetti (Istituto de Fisica, Univ. di Parma, Parma, Italy), P.P.Lottic L.Zanotti, M.Curti.

Phys. Status Solidi b (Germany), vol.118, no.2, p.743-9 (1 Aug. 1983).

The growth and Raman scattering results obtained for $ZnGa_{2x}In_{2(-x)}S_4$ $Zn_xCd_{1-x}Ga_2S_4$, and $CdGa_{2x}In_{2(1-x)}S_4$ tetragonal pseudoternary compounds are given and discussed. The phonon spectra display one- and two-mode behaviour. For $Zn_xCd_{1-x}Ga_2S_4$ compounds a virtual crystal model seems to describe the observed one-mode behaviour. (12 refs.)

108950 Directional dependence of extraordinary infrared oscillator parameters of $TlGaS_2$-type layer crystals. N.M.Gasanly, A.S.Ragimov V.I.Tagirov (Dept. of Phys., Azerbaijan State Univ., Baku, Azerbaidzhan SSR).

Physica B & C (Netherlands), vol.122B+C, no.1, p.28-34 (Sept. 1983).

The directional dispersion of IR-active modes of $TlGaS_2$, $TlGaSe_2$ and TlInS layer single crystals has been investigated, depending on the angle between the phonon wave vector *q* and the optical *c*-axis. Owing to the possibility o preparation crystals with various orientations of reflecting surfaces with respect to the optical *c*-axis, it was of interest to check the applicability of the generalized Born and Huang theory of long-wave optical vibrations in uniaxia crystals to $TlGaS_2$-type layer crystals. (16 refs.)

108951 Anharmonic effects in light scattering due to optical phonons in silicon. M.Balkanski, R.F.Wallis, E.Haro (Lab. de Phys. des Solides, CNRS Univ. Pierre et Marie Curie, Paris, France).

Phys. Rev. B (USA), vol.28, no.4, p.1928-34 (15 Aug. 1983).

Systematic measurements by light scattering of the linewidth and frequency shift of the $\vec{q}=0$ optical phonon in silicon over the temperature range of 5-1400K are presented. Both the linewidth and frequency shift exhibit a quadratic dependence on temperature at high temperatures. This indicates the necessity of including terms in the phonon proper self-energy corresponding to four-phonon anharmonic processes. (13 refs.)

108952 B_{1g} mode softening in FeF_2. D.J.Lockwood, R.S.Katiyar V.C.Y.So (Phys. Div., Nat. Res. Council, Ottawa, Ontario, Canada).

Phys. Rev. B (USA), vol.28, no.4, p.1983-7 (15 Aug. 1983).

Experiments are reported for the temperature dependence of phonon Raman scattering in FeF_2. The B_{1g} phonon exhibits anomalous frequency softening with decreasing temperature for temperatures in the range $T_N=78$-340K This softening is less marked for temperatures below T_N because of spin-lattice effects resulting from the antiferromagnetic ordering. In the higher-temperature region the square of the B_{1g}-phonon frequency is proportional to temperature, which is suggestive of a virtual structural phase transition However, consideration of other work on the pressure dependences of the Raman-active modes in similar compounds leads the authors to conclude that the mode softening results largely from the lattice thermal contraction. This contraction disproportionally influences the forces between the nearest-neighbor fluorine ions in adjacent planes perpendicular to the *c* axis. (1 refs.)

108953 Theoretical study of the infrared absorption in trans-$(CH)_x$ and trans-$(CD)_x$. D.Rakovic (Faculty of Electrical Engng., Belgrade, Yugoslavia), I.Bozovic, S.A.Stepanyan, L.A.Gribov.
Phys. Rev. B (USA), vol.28, no.4, p.1997-2000 (15 Aug. 1983).
A calculation of the vibration spectra of trans-$(CH)_x$ and trans-$(CD)_x$ is presented; it includes for the first time the out-of-plane motions and the infrared (IR) absorption intensities. To obtain a reliable set of transferable parameters, extensive simultaneous optimizations of both the force constants and the electro-optical parameters were performed to solve the inverse spectral problem for several short polyenes. The calculations evince a novel major effect in trans-polyacetylene: the A_u in-plane C-H bending mode is expected to give rise to the strongest IR absorption band at ~ 1300 cm^{-1} but its intensity is in fact dramatically reduced. The same effect is seen in the deuterated polymer. Lowering of the resonant Raman frequencies and the IR band disappearance are both believed to be caused by coupling of the vibrations to the π-electron system. For the IR case this is probably caused by the large dipole moments of the vibrating C-H bonds. (24 refs.)

108954 Light scattering from vibrational modes in GaAs-$Ga_{1-x}Al_xAs$ superlattices and related alloys. J.Sapriel, J.C.Michel, J.C.Toledano (CNET, Bagneux, France), R.Vacher, J.Kervarec, A.Regreny.
Phys. Rev. B (USA), vol.28, no.4, p.2007-16 (15 Aug. 1983).
Raman and Brillouin scattering investigations are performed on GaAs-$Ga_{1-x}Al_xAs$ superlattices which have been fully characterized by means of X-ray diffraction. Six superlattice samples with periods ranging from 45 to 250 Å and with an aluminum concentration x around 0.3 have been investigated by means of conventional Raman scattering. A doublet of lines due to the superlattice effect appears on the spectra. These Raman lines of symmetry A_1 are located on either side of the theoretical value corresponding to the first folded mode at $k=0$ of the longitudinal-acoustic branch. The crystalline quality of the GaAs layers of the superlattices has also been studied through comparisons between disorder-activated transverse-acoustic modes and second-order Raman lines. Precise measurements on surface-acoustic-wave velocity have been performed by means of a high-contrast and high-sensitivity Brillouin experimental setup. Several $Ga_{1-x}Al_xAs$ epitaxial layers with $0<x<0.8$ have been studied and the velocity variations in the [100] and [110] directions have been determined. The elastic constants of $Ga_{1-x}Al_xAs$ undergo small decrease with increasing values of x. Concerning the Brillouin measurements in GaAs-$Ga_{1-x}Al_xAs$ superlattices, the surface-wave velocities are slightly higher than in the corresponding mean homogeneous medium. Possible stresses in the alternating layers could be at the origin of this difference. (29 refs.)

108955 Light scattering studies of rubidium cyanide under hydrostatic pressure. W.Dultz, E.Rehaber (Fakultat fur Phys., Univ. Regensburg, Regensburg, Germany).
Phys. Rev. B (USA), vol.28, no.4, p.2114-18 (15 Aug. 1983).
The Raman and Brillouin spectra of RbCN were measured at pressures up to 0.8 GPa and at temperatures down to 80K. The phase diagram of RbCN was obtained by using the change of the spectra at a phase transition as indicator for the phase line. The Raman spectra of the different phases of RbCN show a similarity to the spectra of the high-pressure phases of KCN and the assignment of several Raman bands with the help of inelastic neutron-scattering data supports this expected correspondence. An introduction of pressure into the Landau-type expansion to describe the pressure dependence of the elastic constant C_{44} is discussed. (32 refs.)

108956 Some problems concerning infrared emission measurements. P.Baraldi, G.Fabbri (Lab. di Chimica Fisica Applicata, Istituto di Chimica Fisica, Univ. di Modena, Modena, Italy).
Spectrochim. Acta Part A (GB), vol.39A, no.8, p.669-75 (1983).
Some emission spectra of supported samples recorded with two experimental arrangements have been discussed. The existence is pointed out of a background emissivity which causes spectra with bands in relief to be recorded only in an optimum thickness range. The experimental behavior observed is in good agreement with the predictions based on some relationships here reported. Application of the latter to emissivity measurements is shown to supply optical constants consistent with the ones obtained by other techniques. (15 refs.)

108957 Spectroscopic characteristics of the ν_{OH} vibration of polychlorophenols in the solid state. J.-P.Bayle, J.Jullien, H.Stahl-Lariviere (Lab. de Chimie Structurale Organique, Univ. Paris-Sud, Orsay, France), N.le Calve, B.Pasquier.
Spectrochim. Acta Part A (GB), vol.39A, no.8, p.677-88 (1983).
Hydroxyl stretching bands of solid chlorophenols at room and liquid nitrogen temperature have been studied by infrared spectroscopy. A complete interpretation of ν_{OH} region is given for six dichlorophenols and pentachlorophenol for which crystal structures are known. The ν_{OH} region can be explained in terms of different hydrogen bonds and correlation field splittings. Moreover, Fermi resonances arise if ν_{OH} is lower than 3300 cm^{-1}. Isotopically diluted crystals have been used in order to eliminate vibrational coupling. The resulting -OH stretching frequencies can be correlated with the corresponding O...O distances. The usual correlation is obtained except for phenols having two chlorines in ortho position. Except in 3,4,5-trichlorophenol for which an O...O distance of about 2.7 Å can be suggested, a small $\Delta\nu_{OH}$ shift is observed in tri- and tetrachlorophenols, which should be consistent, rather long ($\simeq 3$ Å) O...O distances. (36 refs.)

108958 Raman studies on local structural disorder in silicon-based amorphous semiconductor films. A.Morimoto, S.Oozora, M.Kumeda, T.Shimizu (Dept. of Electronics, Kanazawa Univ., Kanazawa, Japan).
Solid State Commun. (USA), vol.47, no.10, p.773-7 (Sept. 1983).
Raman scattering and ESR measurements were carried out for amorphous Si and amorphous Si-based alloy systems such as Si-N and Si-C. A pronounced broadening of the Si-Si TO-like band of Raman spectra is observed with an increase in the N or C content for amorphous Si-N and Si-C alloy systems. The broadening of the TO-like band for amorphous Si system as well as amorphous Si-N and Si-C systems has a good correlation with an increase in the density of dangling bonds derived from ESR measurements. The fact suggests that dangling bonds are produced in order to relax the local strain due to structural constraint and lower the total energy. (15 refs.)

108959 Raman spectra of low-lying longitudinal model of KH_2PO_4 and KD_2PO_4 in ferroelectric phase. Y.Tominaga (Dept. of Phys., Ochanomizu Univ., Tokyo, Japan), M.Kasahara, H.Urabe, I.Tatsuzaki.
Solid State Commun. (USA), vol.47, no.10, p.835-7 (Sept. 1983).
The origin of the low-lying modes of KH_2PO_4 and KD_2PO_4 in the ferroelectric phase has been clarified by the $z(xy)\bar{z}$ Raman scattering experiments. The '*S*-mode', which has been usually assigned to the proton tunneling mode in KH_2PO_4 at $T<T_c$, has been found in the $z(xy)\bar{z}$ spectrum of KH_2PO_4 in contrast to the $x(yx)y$ spectrum. It has been found that the frequency of the '*S*-mode' of KD_2PO_4 is higher than that of KH_2PO_4. From the present Raman spectroscopy, it is concluded that the '*S*-mode' is assigned to the libration mode of the PO_4 tetrahedrons. (14 refs.)

108960 Observation of disappearance of cooperative Jahn-Teller distortion in the two-dimensional magnetic system $K_2Cu_xZn_{1-x}F_4$ by Raman scattering experiments. Y.Natsume, I.Yamada (Dept. of Phys., Chiba Univ., Chiba, Japan).
Solid State Commun. (USA), vol.47, no.10, p.839-42 (Sept. 1983).
Raman spectra in the two-dimensional diluted system $K_2Cu_xZn_{1-x}F_4$ are reported. The problem how the cooperative Jahn-Teller distortion (whose existence in the *c*-plane is well confirmed for K_2CuF_4) is destroyed with decreasing x is discussed on the basis of observed behaviours of Stokes lines for some characteristic vibrational modes in spectra. (13 refs.)

78.35 BRILLOUIN AND RAYLEIGH SCATTERING

108961 On the quantum statistics of Brillouin scattering. A.Pieczonkova (Inst. of Phys., Czechoslovak Acad. Sci., Praha, Czechoslovakia).
Czech. J. Phys. Sect. B (Czechoslovakia), vol.B33, no.8, p.923-9 (1983).
The statistical properties of photon and phonon fields in Brillouin scattering with intense pumping are analysed, for the case of prevailing Stokes interaction. The effect of antibunching of photons is demonstrated using the photon number distribution and its factorial moments. The time dependence of the integrated intensity (of the first factorial moment) of photon and phonon modes is discussed from the viewpoint of the strength of anti-Stokes interaction. (9 refs.)

108962 A new look at the enhanced low-angle scattering in moderately concentrated polymer solutions. J.-M.Guenet, N.F.F.Willmott, P.A.Ellsmore (H.H. Wills Phys. Lab., Bristol Univ., Bristol, England).
Polym. Commun. (GB), vol.24, no.8, p.230-3 (Aug. 1983).
In the light of the recent discovery by Tan et al. (Macromolecules, vol.16, p.28, 1983) of the gelation ability of some atactic polystyrene solutions at low temperature above the UCST, the present authors reexamine the enhanced scattering observed at small angles in moderately concentrated solutions. Some results gained from light scattering experiments are presented, showing that there seems to be a correlation between these two phenomena: i.e. no abnormal scattering effect when dealing with a solvent preventing gelation

whereas abnormal scattering when using a solvent promoting the gelation. The results are discussed and a tentative explanation is given. (16 refs.)

108963 Rayleigh and Brillouin scattering in $RbH_3(SeO_3)_2$ near the phase transition temperature. A.Sakai, T.Yagi (Dept. of Phys., Kyushu Univ., Fukuoka, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2544-9 (July 1983).
Rayleigh and Brillouin scattering spectra of $RbH_3(SeO_3)_2$ have been observed around the phase transition temperature T_c. The temperature dependence of the Brillouin frequency shifts shows a small anomaly near T_c in all the three principal directions. The sound-velocity dispersion is found only in the c_{55} transverse mode. The intensity of the Rayleigh component is insensitive to temperature even just near T_c. The existence of dynamic clusters above T_c is discussed and its characteristic frequency is roughly estimated, while static clusters are concluded not to exist in the same temperature region. (19 refs.)

108964 Method of measuring the kinetic and thermodynamic properties in binary stratified systems by means of scattered light spectra. S.V.Kazakov, N.I.Chernova (M.V. Lomonosov Moscow State Univ., Moscow, USSR).
J. Eng. Phys. (USA), vol.44, no.1, p.55-9 (Jan. 1983). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.44, no.1, p.67-71 (Jan. 1983). [received: Sept. 1983]
A method and results of investigating the kinetic and thermodynamic parameters of the mutual diffusion coefficient in binary stratified liquid mixtures are described. (12 refs.)

108965 Heterodyne correlation of scattered light from a Sr^{++}-doped NaCl crystal. A feasibility study. D.Sahoo (Materials Sci. Labs., Reactor Res. Centre, Kalpakkam, Tamil Nadu, India).
Phys. Status Solidi b (Germany), vol.118, no.2, p.623-30 (1 Aug. 1983).
A theoretical calculation of the heterodyne correlation function of scattered light is presented for a (suitably heated-treated) NaCl crystal doped with 250 ppm divalent Sr^{++} impurities. It is assumed that the impurity-vacancy complexes (A_1) diffuse and aggregate to form dimers (A_2) and trimers (A_3) by the reactions $A_1+A_1 \rightleftharpoons A_2$ and $A_2+A_1 \rightleftharpoons A_3$. Light scattering arises arises due to fluctuations in concentrations of A_1, A_2, and A_3. The correlation function, calculated under equilibrium conditions is a sum of three decaying exponentials. It reduces to 85% (or its initial value) in 10 ms at 800K, to 30% in 10 s at 600K, and to 6% in 10 s at 500K, thus indicating the feasibility of the experiment at relatively high temperatures. (10 refs.)

108966 Theory of light scattering in cholesteric blue phases. R.M.Hornreich, S.Shtrikman (Dept. of Electronics, Weizmann Inst. of Sci., Rehovot, Israel).
Phys. Rev. A (USA), vol.28, no.3, p.1791-807 (Sept. 1983).
A comprehensive analysis of elastic light scattering in cholesteric liquid-crystal systems, based upon the Mueller matrix approach, is given. Emphasis is placed upon analyzing the polarization state of the scattered light for arbitrarily polarized incident radiation. The theory is applied to the ordered cholesteric blue phases BPI and BPII, which exhibit long-range orientational ordering. Both the polycrystalline and single-crystal cases are considered and the role played by optical activity is studied. It is shown how light-scattering studies yield information on the structural properties of the ordered phases. The quasielastic light scattering due to excitations in the disordered phase is also analyzed in the harmonic approximation. It is shown that this scattering cannot explain the strong anomalous scattering observed in the amorphous BPIII phase. (25 refs.)

108967 Low-angle laser light scattering from polystyrene solutions: intensity measurements and photon correlation spectroscopy. E.Ozdemir, R.W.Richards (Dept. of Pure & Appl. Chem., Univ. of Strathclyde, Glasgow, Scotland).
Polymer (GB), vol.24, no.9, p.1097-102 (Sept. 1983).
Light scattering measurements have been made on polystyrenes with a range of molecular weights in toluene and for one polystyrene in a range of solvents including a theta solvent. Intensity data were used to calculate second virial coefficients and molecular weights, whilst photon correlation spectroscopy was used to calculate diffusion coefficients. All measurements were made at 30°C and at a scattering angle of ca.4°. The data were used to examine current theories of polymer diffusion and the relation between hydrodynamic radius (R_H) and radius of gyration ($\langle s^2\rangle^{1/2}$). The results support accepted theories of polymer diffusion, but suggest that the relation between R_H and $\langle s^2\rangle^{1/2}$ requires further analysis. (36 refs.)

108968 Use of phase Fourier spectroscopy to investigate dynamic scattering of light in nematic liquid crystals. V.L.Pankov, V.N.Strekalov, V.P.Tychinskii (Inst. of Radio Engng., Electronics & Automatics, Moscow, USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.2, p.205-8 (March-April 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.2, p.351-7 (March-April 1983). [received: Sept. 1983]
Phase Fourier spectroscopy is used to investigate the low-frequency spectra of phase fluctuations of light scattered by a liquid crystal with a resolution of 10^{-3} Hz. In the transitional region from a stationary domain structure to the dynamic scattering regime, there are periodic disturbances in the nematic liquid crystal with a characteristic frequency of 0.3-0.5 Hz. 78.40 VISIBLE AND ULTRAVIOLET SPECTRA

108969 Polarized emission of $[Ru(bpy)_3](PF_6)_2$ single crystals. H.Yersin, E.Gallhuber (Inst. fur Phys. & Theoretische Chem., Univ. Regensburg, Regensburg, Germany), A.Vogler, H.Kunkely.
J. Am. Chem. Soc. (USA), vol.105, no.13, p.4155-6 (29 June 1983).
Polarized emission spectra of single-crystal $[Ru(bpy)_3](PF_6)_2$ are reported for the first time. The spectra are recorded in the temperature range from $T=243$ to 343K. A new $\mathbf{E}\|\mathbf{c}$-polarized emission band is found, situated 650 $cm^{-1}\pm 20\%$ above the main emission peak maximum. The corresponding emitting state is assigned to A_2' (in D_3'). The $\mathbf{E}\perp\mathbf{c}$-polarized emission results from one or more E′ states and is by a factor of about 20 more intense than the $\mathbf{E}\|\mathbf{c}$-polarized emission. (19 refs.)

108970 Absorption spectra, energy levels, and crystal-field analysis of trivalent neodymium in the γ phase of neodymium sesquisulfide (γ-Nd_2S_3). J.B.Gruber (Depts. of Phys. & Chem., Portland State Univ., Portland, OR, USA), R.P.Leavitt, C.A.Morrison.
J. Chem. Phys. (USA), vol.79, no.4, p.1664-8 (15 Aug. 1983).
The authors report absorption spectra of Nd^{3+} in the γ phase of Nd_2S_3. Energy levels of all manifolds from the ground state ($^4I_{9/2}$) through $^2H_{11/2}$ (15616 cm^{-1}) were determined from the spectra. A best least-squares fit of the experimental levels was made with a crystal-field Hamiltonian of S_4 symmetry, resulting in the following crystal-field parameters B_{km} (in cm^{-1}): $B_{20}=-209$, $B_{40}=402$, $B_{44}=1236$, $B_{60}=-774$, $RB_{64}=-423$, and $IB_{64}=103$. The r.m.s. deviation between calculated and experimental levels is 8.7 cm^{-1}. A total of 50 levels was included in the fit (out of a possible 53 within the manifolds considered). The results are shown to be consistent with an effective point-charge model for the γ-Nd_2S_3 lattice in which Nd^{3+} vacancies are distributed randomly. (26 refs.)

108971 Dynamic light scattering of polystyrene latex in the ordered state. S.Sasaki (Dept. of Phys. & Macromolecular Chem., Univ. of Leiden, Leiden, Netherlands), N.Imai.
J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2571-80 (July 1983).
A Laue pattern is observed for the ordered array of polystyrene latex particle. The pattern corresponds well to a fcc lattice. The time correlation of intensity of scattered light, $g^{(1)}(\tau)$, is also measured and analyzed. The intensity fluctuation of Laue spot shows a long time-correlation which can be approximately expressed as $g^{(1)}(\tau)\sim(\tau)^{-0.61}$ at longer correlation time. The fact that decay constants, Γ, of $g^{(1)}(\tau)$ show maximum at the half of the scattering angle of the Laue condition indicates that the movement of particle is correlated with each other.

108972 Optical absorption near the fundamental absorption edge in some vanadate glasses. C.A.Hogarth, A.A.Hosseini (Dept. of Phys., Brunel Univ., Uxbridge, England).
J. Mater. Sci. (GB), vol.18, no.9, p.2697-705 (Sept. 1983).
The fundamental absorption edges of some samples of V_2O_5-P_2O_5 and V_2O_5-P_2O_5-TeO_2 glasses were measured in the short wavelength part of the visible region, and it was found that the fundamental absorption of these glasses is dependent on composition and arises from direct forbidden transitions and occurs at a photon energy in the range 1.9 to 2.6 eV, depending on composition. (9 refs.)

108973 Study of the thermal stability of textile materials (fibers) by spectroscopic techniques. A.S.Kozeruk, S.G.Guminetskii.
J. Appl. Spectrosc. (USA), vol.37, no.5, p.1281-5 (Nov. 1982). Translation of: *Zh. Prikl. Spektrosk. (USSR)*, vol.37, no.5, p.795-800 (Nov. 1982). [received: Sept. 1983]
The authors study the influence of elevated temperatures on the spectral shape and the magnitude of the absorption coefficients (A) of several of the undyed fibers most widely employed. Since fibers very effectively scatter light incident on them, due to their disperse nature, measurements of the absorption coefficients were carried out using a high temperature integral photometer. Undyed fibers may luminesce under the action of ultraviolet radiation. They have also observed this, and find that the intensity of this luminescence varies as the temperature is raised. In order to avoid this emission, which impedes the measurement of the absorption coefficients of fibers in the 'pure' form in the spectral region $\lambda<400$ nm, they employed a glass filter (transmission region $\lambda=240$-400 nm), which was placed directly in front of the photomultiplier cathode. (11 refs.)

108974 Optical absorption and magnetic circular dichroism of MnI_2. H.J.W.M.Hoekstra, P.R.Boudewijn, H.Groenier, C.Haas (Lab. of Inorganic Chem., Univ. Groningen, Groningen, Netherlands).
Physica B & C (Netherlands), vol.121B+C, no.1-2, p.62-80 (1983).
Absorption and magnetic circular dichroism (MCD) spectra of single crystals of MnI_2 in the spectral region 16000-30000 cm^{-1} at temperatures between 1.5 and 300K are reported. The observed bands are due to d-d transitions of the Mn^{2+} ions. Parameters of the electron repulsion, the cubic crystal field and the spin orbit coupling are deduced from the spectra. The transitions are induced by vibronic interactions with ungerade phonons and by exchange interactions between neighbouring ions. The relative contribution of these two mechanisms is different for different transitions. MCD parameters calculated for a trigonally-anisotropic coupling of Mn^{2+} with ungerade phonons are compared with the observed spectra. A detailed assignment is given for the fine structure of the $^6Ag_{1g}\rightarrow{}^4A_{1g}$, ^4E_g transitions. These transitions show the effects of exciton diffusion, with an effective exciton hopping integral of 9 cm^{-1}. (40 refs.)

108975 Excitonic reflectance of GaAs crystals cleaved in liquid helium. L.Schultheis, I.Balslev (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany).
Phys. Rev. B (USA), vol.28, no.4, p.2292-5 (15 Aug. 1983).
The authors report optical reflectance spectra near the $n=1$ excitonic resonance of GaAs. The experimental results from crystals cleaved in liquid helium and exposed to air exhibit noticeable changes of the line shape. Comparison with a model based on the adiabatic approximation indicates that line-shape distortions by surface electric fields are unavoidable for air-exposed GaAs surfaces. (20 refs.)

108976 Study of the 2.4 and 2.6 eV absorption bands in CdMnTe. J.P.Lascaray, J.Diouri, M.El Amrani, D.Coquillat (Univ. Sci. & Tech. du Languedoc, Montpellier, France).
Solid State Commun. (USA), vol.47, no.9, p.709-12 (Sept. 1983).
Two absorption bands, located around 2.4 and 2.6 eV, are observed in highly Mn-doped CdMnTe absorption spectra. They are studied in the temperature range 5 to 300K. The strong similarity between these results and previous data in Mn compounds suggest an intra-Mn nature of the transitions responsible for the two bands. From this point of view, different hypotheses involving $Mn^{2+}(^4G)$ excited state split by the crystal field are advanced and compared with available data. (16 refs.)

108977 Absorption and dispersion of optical glass intrinsic absorption in vacuum ultraviolet region. T.Izumitani, S.Hirota.
Wiss. Z. Friedrich-Schiller-Univ. Jena, Math. Naturwiss. Reihe (Germany), vol.32, no.2-3, p.227-37 (1983). In English. (Otto-Schott-Colloquium on the State of Optical Glass Research 1982, Jena, Germany, 1982).
The intrinsic absorption spectrum of glass in the vacuum ultraviolet region was measured in order to correlate dispersion to absorption of glass. The absorption wavelength of bridging oxygen, non-bridging oxygen and non-noble type cations such as Pb^{2+} was confirmed by reflection spectra in R_2O-RO-SiO_2 glasses, and by the absorption spectra in thin film BaO-$R_{m/n}O$-$B_{2/3}O$ glasses. The absorption wavelengths of bridging oxygen ions are found at 11.6 eV and 10.4-9.5 eV, those of non-bonding oxygen ions are found in the range of 9-7 eV. The oscillator strength of bridging oxygen ions is significantly higher than that of non-bridging oxygen ion. (7 refs.)

78.45 STIMULATED EMISSION

(see also 42.65C in nonlinear optics)

108978 New inorganic material with a high concentration of Nd^{3+} ions for obtaining stimulated emission at the $^4F_{3/2}\rightarrow{}^4I_{11/2}$ and $^4F_{3/2}\rightarrow{}^4I_{13/2}$ transitions. A.A.Kaminskii, S.E.Sarkisov, B.V.Mill', G.G.Khodzhabagyan (A.V. Shubnikov Inst. of Crystallography, Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1189-91 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1396-7 (Aug. 1982).
A series of $(La_{1-x}Nd_x)_3Ga_5SiO_{14}$ crystals with $x=0.0001$ to 1.0 with a [0001] ($\|$c) orientation, a weight up to 150 g, and a diameter equal to 20-25 mm was grown from Pt crucibles measuring 42×43 mm and containing 300-350 g of a melt of stoichiometric composition by the Czochralski method on a Malvern MRS-2 automated apparatus. The experiments were carried out in a flowing atmosphere of a mixture of 3% O_2+97% N_2. The melting point of the entire $(La_{1-x}Nd_x)_3Ga_5SiO_{14}$ series is close to 1470°C. The neodymium entry factor is equal to unity. The X-ray diffraction characteristics of $La_3Ga_5SiO_{14}$ are: $\alpha=8.162$, $c=5.087$ Å; and $\rho=5.754$ g/cm^3. The values for $Nd_3Ga_5SiO_{14}$ are: $\alpha=8.064$, $c=5.056$ Å, and $\rho=6.024$ g/cm^2. The parameters of the crystals of the solid solutions have the corresponding intermediate values. The concentration of the Nd^{3+} ions in $Nd_3Ga_5SiO_{14}$ is 1.05×10^{22} cm^{-3}. The experiments on the excitation of stimulated emission were carried out at 300K with the use of an ISP-250 Xe lamp. The preliminary complex luminescence-absorption investigations of $La_3Ga_5SiO_{14}$-Nd^{3+} made it possible to determine spectroscopy characteristics. (6 refs.)

108979 Growth and stimulated emission spectroscopy of $Ca_3Ga_2Ge_3O_{12}$-Nd^{3+} garnet crystals. A.A.Kaminskii (A.V. Shubnikov Inst. of Crystallography, Acad. of Sci., Moscow, USSR), B.V.Mill, A.V.Butashin.
Phys. Status Solidi a (Germany), vol.78, no.2, p.723-32 (16 Aug. 1983).
Physical-chemical conditions of synthesis are found and a set of $Ca_3Ga_2Ge_3O_{12}$ single crystals with the concentration of Nd^{3+}ions from 0.05 till 16 at.% for the experiment on the stimulated emission generation is grown by the Czochralski technique using platinum crucibles. The formation of macrodefects as a function of crystal growth conditions is investigated. On the case of detailed concentration and temperature investigations of the luminescence and stimulated emission in the $^4F_{3/2}\rightarrow{}^4I_{11/2}$ and $^4F_{3/2}\rightarrow{}^4I_{13/2}$ channels the formation of activator centres of Nd^{3+} in $Ca_3Ga_2Ge_3O_{12}$ is analyzed. The way to improve the generation parameters of Nd^{3+} ions by coactivating Cr^{3+} sensitizer ions into $Ca_3Ga_2Ge_3O_{12}$ is discussed. The possibility to excite stimulated emission also for the chromium ions in the red region of the spectrum is noted. The perspective of using multication garnets with heterovalent isomorphism to produce disorder laser garnet crystals doped with Nd^{3+} ions is pointed out. (31 refs.)

78.50 IMPURITY AND DEFECT ABSORPTION IN SOLIDS

108980 Vibrational absorption bands for implanted nitrogen in crystalline silicon. H.J.Stein (Sandia Nat. Labs., Albuquerque, NM, USA).
Appl. Phys. Lett. (USA), vol.43, no.3, p.296-8 (1 Aug. 1983).
Infrared absorption bands for ^{15}N in crystalline silicon have been observed for the first time. Isotopic substitution experiments were performed by N^+ ion implantation into crystalline silicon to confirm the role of nitrogen in absorption bands at 764 and 962 cm^{-1} for ^{14}N and at 748 and 937 cm^{-1} for ^{15}N. Laser annealing increases the intensity of the higher frequency band. The 962-cm^{-1} band frequency is close to Si-N stretch frequencies for planar bonded N in crystalline Si_3N_4. It is suggested that the lower frequency band is associated with a mode that is made IR active by local distortion, consistent with a distorted substitutional N center identified by Brower (1982) in electron paramagnetic resonance studies on laser-annealed nitrogen-implanted Si. (14 refs.)

108981 Oxygen vacancies in lithium niobate. K.L.Sweeney, L.E.Halliburton (Phys. Dept., Oklahoma State Univ., Stillwater, OK, USA).
Appl. Phys. Lett. (USA), vol.43, no.4, p.336-8 (15 Aug. 1983).
Optical absorption peaks at 760 and 500 nm in $LiNbO_3$ are assigned to oxygen vacancies containing one and two electrons, respectively. The 500-nm band appears after annealing above approximately 500°C in a vacuum, i.e. a reducing atmosphere, and continues to grow with increasing anneal temperature. Optical bleaching near 77K destroys the band at 500 nm and produces both a band at 760 nm and a Nb^{4+} electron spin resonance spectrum. The spectral dependence of the bleaching light required to convert the 500-nm band to the 760-nm band is determined. (10 refs.)

108982 Absorption spectrum of Ni^{2+} doped in NH_4Br single crystal. T.R.Griffiths (Dept. of Inorganic and Structural Chem., Univ. of Leeds, Leeds, England), S.V.J.Lakshman, A.V.Rajulu.
J. Crystallogr. & Spectrosc. Res. (USA), vol.13, no.4, p.253-62 (Aug. 1983).
The optical absorption spectrum of Ni^{2+} doped in NH_4Br single crystals has been studied at room and liquid-air temperatures. The observed ambient bands at 6300, 11600, 13400, 18500 and 20000 cm^{-1} have been assigned, respectively, to the transitions $^3A_2(F)\rightarrow{}^3T_2(F)$, $^3T_1(F)$, $^1E(D)$, $^1T_2(D)$, and $^3T_1(P)$. The crystal field parameters evaluated are $D_q=630$ cm^{-1}, $B=850$ cm^{-1}, and $C=3600$ cm^{-1}. In assigning the location of Ni^{2+} ions within the lattice, evaluations are made of the (limited) extant comparable data. It is then concluded that Ni^{2+} enters an octahedral interstitial, rather than a substitutional, site. It is surrounded by four bromide ions, in a plane, with two polarized water molecules at the opposing fifth and sixth positions. (19 refs.)

108983 Cobalt centres in ammonium chloride: optical absorption studies. B.Rambabu (Dept. of Phys., Indian Inst. of Technol., Madras, India), C.Ramasastry, B.V.R.Chowdari.
Phys. Status Solidi b (Germany), vol.118, no.2, p.541-9 (1 Aug. 1983).
The optical absorption data for Co^{2+} ions in NH_4Cl single crystals grown under different conditions and measured in the temperature range of 300 to 10K are presented. The observed absorption spectrum is interpreted by considering the absorption within the crystal field levels determined mainly by the ligands of octahedral coordination. The spectrum at low temperatures is considered to be due to two different centres in which the Co^{2+} ion occupies an interstitial position, i.e. the centre of a square of four Cl^- ions with either two NH_3 ions or H_2O ions on either side of the square. In addition to these, the stabilization of a centre in which a Co^{2+} ion occupies an edge centre position at room temperature is also suggested. The crystal field parameters for the cobalt centres stable at low temperature are evaluated. (23 refs.)

108984 Nickel centers in strontium tartrate tetrahydrate single crystals. N.Satyanarayana, K.Hariharan, S.Radhakrishna (Dept. of Phys., Indian Inst. of Technol., Madras, India).
Physica B & C (Netherlands), vol.122B+C, no.1, p.67-73 (Sept. 1983).
Optical absorption of Ni^{2+} doped in strontium tartrate tetrahydrate ($SrTr.4H_2O$) has been studied at room temperature (300K) and at liquid nitrogen temperature (80K). Polarised absorption studies along the three crystallographic axes have also been carried out. The spectrum shows the characteristic features of Ni^{2+} in a distorted octahedral field. A good fit between calculated and experimental band positions has been obtained. The crystal field parameters Dq, B and C are calculated by using the energy matrices and energy equations ($Dq=850$ cm^{-1}, $B=930$ cm^{-1} and $C=4000$ cm^{-1}) and the crystal field transitions are assigned. A correlation of the ESR and observed changes in optical absorption spectra after irradiation indicates the formation of Ni^{3+}. (16 refs.)

108985 Oxygen and carbon measurements on silicon slices by the IR method. P.Stallhofer, D.Huber (Wacker Chemitronic, Burghausen, Germany).
Solid State Technol. (USA), vol.26, no.8, p.233-7 (Aug. 1983).
Oxygen has recently attracted a lot of attention in the manufacture of silicon semiconductors due to its inherent potential for denuded zone formation and positive defect engineering. Its concentration is measured by the infrared absorption method which, as an optical method, also depends on the transmission or reflection conditions of the wafer surfaces, i.e. polished or back damaged surfaces. These different surface conditions modify the transmission formula for the calculation of the exact oxygen content. The exact equations are given for most examples of today's state-of-the-art silicon wafer technology. (7 refs.)

108986 Influence of elementary structure defects on the optical properties of glasses. J.R.Zakis, A.R.Silin.
Wiss. Z. Friedrich-Schiller-Univ. Jena, Math. Naturwiss. Reihe (Germany), vol.32, no.2-3, p.185-92 (1983). In Russian. (Otto-Schott-Colloquium on the State of Optical Glass Research 1982, Jena, Germany, 1982).
The common rules of the influence of elementary structure defects on optical glass properties are discussed and models of these defects in the simple silicate glasses are given. The simplest intrinsic defects in the fused silica are the stabilized components of the broken Si-O bond. The optical and ESR of E centers are causes by neutral threefold coordinated silicon atoms. Neutral non-bridging oxygen atoms are responsible for the absorption at 4.75 and 2.0 eV and red luminescence at 1.9 eV excited in these absorption bands. The geometric model of this center consists of an isolated non-bridging oxygen atom, displaced from the threefold symmetry axis of the tetrahedron and rotating around it (dynamic Jahn-Teller effect). The non-bridging oxygen atoms are also the elementary defects in sodium silicate glasses and give rise for the induced absorption at 2.0 eV. (29 refs.)

78.55 PHOTOLUMINESCENCE

108987 Photoluminescence associated with thermally induced microdefects in Czochralski-grown silicon crystals. M.Tajima (Max-Planck-Inst. fur Festkorperforschung, Stuttgart, Germany), U.Gosele, J.Weber, R.Sauer.
Appl. Phys. Lett. (USA), vol.43, no.3, p.270-2 (1 Aug. 1983).
Photoluminescence in the photon energy range 0.7-1.2 eV is investigated for commercial Czochralski-grown Si crystals subjected to isothermal annealing at 650°C for 1-450 h. A strong and sharp line appears at 0.903 eV at certain annealing stages, regardless of the sources and the conductivity type of starting materials. The intensity dependence of the 0.903-eV line on the annealing time coincides with the concentration dependence expected for Si self-interstitials emitted during the oxygen precipitation process. This is experimental evidence that microdefects responsible for this line are correlated with Si self-interstitials. (20 refs.)

108988 Photoluminescence of GaAs-Al$_x$Ga$_{1-x}$As multiple quantum well structure under high excitations. Z.Y.Xu, V.G.Kreismanis, C.L.Tang (Cornell Univ., Ithaca, NY, USA).
Appl. Phys. Lett. (USA), vol.43, no.5, p.415-17 (1 Sept. 1983).
Allowed transitions between the $n=1$, 2, and 3 subbands of the conduction and valence bands of a multiple quantum well heterostructure of GaAs-Al$_{0.6}$Ga$_{0.4}$As are seen in spontaneous emission under high excitations. The observed peaks agree very well with the calculated locations of the peaks when the finite depth of the potential well and the nonparabolicity of the conduction band are taken into account. The same basic features are seen under CW or picosecond pulse excitation and at room temperature, 77K, or 4.2K. (6 refs.)

108989 Effect of growth temperature on the photoluminescent spectra of undoped AlGaAs grown by metalorganic-chemical vapour deposition. K.Mohammed, J.L.Merz (Dept. of Electrical & Computer Engng., Univ. of California, Santa Barbara, CA, USA), D.Kasemset.
Mater. Lett. (Netherlands), vol.2, no.1, p.35-8 (July 1983).
A detailed investigation of the effect of substrate growth temperature on the optical properties of AlGaAs grown by metalorganic-chemical vapour deposition is reported, using room- and low-temperature photoluminescence. A monotonic increase in band-to-band photoluminescence is observed as the growth temperature is increased from 700 to 800°C. At the same time, however, an increase in the incorporation of C and Ge acceptors is observed. (13 refs.)

108990 Quantum yield of the guest in the linear chain of molecules. I.Barvik, V.Szocs (Inst. of Phys., Charles Univ., Praha, Czechoslovakia).
Czech. J. Phys. Sect. B (Czechoslovakia), vol.B33, no.9, p.1016-23 (1983).
Calculation of the quantum yield of the quest in linear finite chains, based on the exact expressions for coherent memory functions, is reported. Illustrative numerical results are given to show the effect of inhomogeneities, boundaries and related magnitudes of relevant parameters on the result. (11 refs.)

108991 Exciplex and heteroexcimer emission from pyrene crystals doped with anthracene derivatives. G.E.Berkovic, Z.Ludmer (Dept. of Structural Chem., Weizmann Inst. of Sci., Rehovot, Israel).
Chem. Phys. Lett. (Netherlands), vol.100, no.1, p.102-4 (26 Aug. 1983).
Excited-state interactions in pyrene crystals doped with various anthracene derivatives are examined. Both donor-acceptor and heteroexcimer-type exciplexes, formed between host and guest molecules, are found. The exciplex ground state is found to be less repulsive than that of the pyrene excimer. (19 refs.)

108992 Spectroscopic properties of Er^{3+} ions in Li(Er, Gd)P$_4$O$_{12}$ single crystals—fluorescence, Raman and infrared spectra. Z.Mazurak, J.Hanuza, K.Hermanowicz, B.Jezowska-Trzebiatowska (Inst. for Low Temperature & Structure Res., Polish Acad. of Sci., Wroclaw, Poland), D.Schultze, C.Waligora.
Chem. Phys. (Netherlands), vol.79, no.2, p.255-67 (1 Sept. 1983).
Spectroscopic investigations of Er^{3+} ions doped in a monoclinic LiGdP$_4$O$_{12}$ crystal, have been carried out. From an analysis of the luminescence and Raman spectra, the Stark splittings of the ^{4}I$_{15/2}$, ^{4}I$_{11/2}$, ^{4}S$_{3/2}$, ^{2}F$_{9/2}$ and ^{4}F$_{7/2}$ manifolds of the Er^{3+} ions were determined with high accuracy. On the basis of the infrared and Raman spectral investigations, structural information has been obtained for the Er^{3+} centers and their oxygen environment. Such characteristics are essential for a theoretical description of functional properties of possible laser materials based on the above-mentioned medium. (17 refs.)

108993 Temperature-independent photoluminescence in amorphous Si$_{1-x}$C$_x$:(F,H) films with low defect density. A.Morimoto, T.Miura, M.Kumeda, T.Shimizu (Dept. of Electronics, Faculty of Technol., Kanazawa Univ., Kanazawa, Japan).
Jpn. J. Appl. Phys. Part 1 (Japan), vol.22, no.6, p.908-11 (June 1983).
Photoluminescence and electron spin resonance measurements were carried out on an amorphous silicon-carbon alloy film containing both F and H (a-Si$_{1-x}$C$_x$:(F,H)) prepared by the glow discharge decomposition of a mixture of SiH$_4$ and CF$_4$ gas. The a-Si$_{1-x}$C$_x$:(F,H) film, which had a wide optical gap (about 2.8 eV), had a smaller spin density and a photoluminescence with a higher intensity at room temperature and with a weaker temperature dependence than the a-Si$_{1-x}$C$_x$:H film with a similar optical gap. The temperature-independent photoluminescence appears to be due to an increase in the width of the band tail caused by the incorporation of F atoms. (21 refs.)

108994 Review of the effect of external action (heat treatment, deformation, irradiation) on the luminescence of GaAs. K.D.Glinchuk, K.Lukat, A.V.Prokhorovich.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.1, p.39-54 (1982). In Russian.
Information published since 1966 is discussed under the headings: general analysis of the changes in intensity, damping kinetics, and quantum effectiveness of the luminescence of GaAs under external effects; changes in the luminescence properties of GaAs during plastic deformation; and changes in the luminescence properties of GaAs on irradiation with high energy particles. (80 refs.) *N.F.S.*

108995 Energy and phase relaxation of phosphorescent *F* centers in CaO. M.Glasbeek, D.D.Smith, J.W.Perry, W.R.Lambert, A.H.Zewail (Arthur Amos Noyes Lab. of Chem. Phys., California Inst. of Technol., Pasadena, CA, USA).
J. Chem. Phys. (USA), vol.79, no.5, p.2145-9 (1 Sept. 1983).
The authors study the temperature-induced inhomogeneous broadening of the no-phonon line in the emission spectrum of the *F* center in CaO. The linewidth can be fitted to $\bar{n}(\bar{n}+1)$, where $\bar{n}$ is the thermally averaged occupation number of phonons with a frequency of 90 cm^{-1}. The results are characteristic of elastic scattering of pseudolocalized phonons at the defect site. These phonons also appear to dynamically couple the Jahn-Teller components of the *F* center in the photoexcited $^3T_{1u}$ state and thus gives rise to a temperature dependence of the lifetime of this phosphorescent state. Finally, from experiments using laser-selective excitation it is concluded that the zero-phonon emission peaking at 571.1 nm does not originate in the *F* center. (16 refs.)

108996 Non-radiative recombination processes and related phenomena in Ge doped As$_2$Se$_3$ glasses. M.Kitamura, T.Ogawa, T.Arai (Inst. of Appl. Phys., Univ. of Tsukuba, Ibaraki, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2561-70 (July 1983).
The photoacoustic and the conventional optical absorption spectra of (As$_2$Se$_3$)$_{100-x}$Ge$_x$ (x=0, 1, 5, 10) glasses were observed at room temperature. The non-radiative recombination processes of these materials were analyzed based on the existence of electron-phonon coupling. The authors found that the non-radiative recombination processes and the photostructural change (PSC) are very well explained by an adiabatic potential and that, in total photon intensity (I_0t) dependence of PSC, the increasing of the sample temperature due to increasing the value of I_0t is very important.

108997 Resonant Raman scattering and hot luminescence at the indirect exciton in BiI$_3$. T.Karasawa, K.Miyata, T.Komatsu, Y.Kaifu (Dept. of Phys., Osaka City Univ., Osaka, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2592-602 (July 1983).
Secondary emission (SE) spectra under excitation around the indirect exciton edge of BiI$_3$ crystals are studied at liquid helium temperatures (LHeT). The spectra consist of one-phonon non-resonant Raman scattering lines and two- and multi-phonon resonant Raman scattering (RRS) lines associated with hot luminescence (HL) bands due to phonon assisted exciton recombinations. Detailed results on excitation-energy and temperature dependences of the spectra are presented. The RRS cross sections are analyzed on the basis of exciton damping processes near the exciton band bottom, and the HL line shapes are discussed on quasi-thermal equilibrium distribution under the same relaxation mechanisms.

108998 Origins of impurity-perturbed fluorescent lines of MnF$_2$. S.Saito, Y.Tanabe (Dept. of Appl. Phys., Univ. of Tokyo, Tokyo, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2936-46 (Aug. 1983).
Electronic excitation ($^6A_{1g}\rightarrow{}^4T_{1g}$) energies in MnF$_2$ with Mg or Ca impurity are studied. The inverse of the force constant matrix (static limit of Green's function) is calculated accurately by the double exponential formula, and the distortions of the lattice around the impurity are obtained from the condition for the lattice to be stable in the harmonic approximation. They are rendered into the normal coordinates of the [MnF$_6$]$^{4-}$ complexes containing the Mn^{2+} ion first, second or third nearest to the impurity, and the variations of their excitation energies due to the distortion of the A_{1g}, $E_{g\theta}$ and $T_{2g\zeta}$ mode are calculated. Effects of these three modes are obtained from the comparison between the observed variation of the excitation energies and the lattice distortion under uniaxial stress, which is calculated from the condition of the minimum potential energy per unit cell.

108999 Intense white photoluminescence in ZnO thin film formed by anodization. H.Nanto (Dept. of Electronics, Kanazawa Inst. of Technol., Ishikawa, Japan), T.Minami, S.Takata.
J. Mater. Sci. (GB), vol.18, no.9, p.2721-6 (Sept. 1983).
Intense white photoluminescence (PL) at room temperature has been observed in ZnO thin films formed by anodization at 26°C. The PL depends on the preparation conditions of the films. The PL is attributed to radiative recombination between localized electrons and holes in gap states which are formed by native defects in the films. It is suggested that the anodized ZnO films might be useful for optoelectronic devices, since the low temperature anodization process used is inexpensive and fast. (34 refs.)

109000 Time-dependent concentration depolarization: a Monte Carlo study. G.L.Hilmes, H.H.Harris, J.P.Riehl (Dept. of Chem., Univ. of Missouri, St. Louis, MO, USA).
J. Lumin. (Netherlands), vol.28, no.2, p.135-46 (May-July 1983).
The phenomenon of time-dependent concentration depolarization is examined by a Monte Carlo procedure. The method described is general and versatile, and allows one to arbitrarily choose absorption and emission molecular polarizations, energy transfer mechanisms, and radial and orientational distribution functions. Comparison is made with recent theoretical results on time-dependent depolarization, and with experimental results on the 'steady-state' depolarization of the phosphorescence of phenanthrene-d$_{10}$. Good agreement is obtained for a wide range of concentrations. (21 refs.)

109001 Study of the photoluminescence spectrum in high purity CdTe. J.E.Espinosa, J.M.Gracia, H.Navarro, A.Zehe (Inst. de Ciencias, Univ. Autonoma de Puebla, Puebla, Mexico), R.Triboulet.
J. Lumin. (Netherlands), vol.28, no.2, p.163-76 (May-July 1983).
A study of the photoluminescence produced by a high purity sample of n-type CdTe of $|N_D-N_A|<10^{14}$ impurities per cm^3 was done at several temperatures, varying from 10 to 35K. Several sharp lines were observed in the spectral region between 1.5 to 1.6 eV plus the well-known 1.4 eV band with several well-defined structures on it. The observed temperature behaviour of the line positions, linewidths and relative intensities allowed the authors to establish the presence of a new transition, located at 10K 21.3 MeV below in energy from the free exciton (FE) line, as well as its first phonon replica. Its nature seems to be transitions originating from the conduction band to an acceptor level, 32 MeV above the valence band. These two lines appear at the same position where previous works had reported the first and second phonon replicas of the FE. A scheme of impurity levels is proposed to explain the observed transitions in terms of previously established levels and this new acceptor level. (16 refs.)

109002 Laser induced emission spectra of Pr^{3+} in CaF$_2$ at low temperatures. J.Chrysochoos, P.W.M.Jacobs, M.J.Stillman (Dept. of Chem., Univ. of Western Ontario, London, Ontario, Canada), A.V.Chadwick.
J. Lumin. (Netherlands), vol.28, no.2, p.177-90 (May-July 1983).
The luminescence spectra of Pr^{3+} in CaF$_2$, excited with the 4765.05 Å line of the argon ion laser at low temperatures, consist of many more emission lines than the maximum allowed via the ^{3}P$_0\rightarrow{}^3$H$_{4,5,6}$; ^{3}F$_{2,3,4}$ transitions of a single Pr^{3+}-site. Based upon their intensity, appropriate splittings and concentration dependence, these emission lines are divided into three groups, attributed to difference sites of Pr^{3+} in CaF$_2$. The existence of Pr^{3+} ions in defect sites of different symmetries is supported by theoretical calculations. The laser emission spectra of Pr^{3+} at low temperatures are compared with room temperature emission spectra obtained with excitation of the ^{3}P$_0$ state alone, and with low temperature spectra of Pr^{3+} in different hosts, reported in the literature. (40 refs.)

109003 Radiative recombination in iridium-doped silver bromide single crystals. J.P.Spoonhower, C.A.Hamer (Res. Labs., Eastman Kodak Co., Rochester, NY, USA).
J. Lumin. (Netherlands), vol.28, no.2, p.191-201 (May-July 1983).
The infrared emission spectrum of iridium-doped silver bromide results from a process that is competitive with the visible emission due to iodide centers in pure AgBr crystals. The emitting species is Ir^{3+}, and experiments are described which help elucidate the nature of the radiative processes involved. (12 refs.)

109004 Low-temperature decay-time measurements on the luminescence of calcium tungstate (CaWO$_4$). G.Blasse, G.Bokkers (Phys. Lab., State Univ. of Utrecht, Utrecht, Netherlands).
J. Solid State Chem. (USA), vol.49, no.1, p.126-8 (Aug. 1983).
The emission and excitation spectra of the blue tungstate luminescence were identical with those reported in the literature. The luminescence intensity is temperature independent up to 280K, and so the decay times of the luminescence of CaWO$_4$ are plotted as a function of temperature. Above 5K all decay curves are single exponential, and below 5K the decay curves are biexponential. In this temperature region there is a slow (τ_s) and a fast (τ_f) decay time. (10 refs.)

109005 Luminescence of tin-activated calcium orthophosphates. M.D.Khalupovskii, V.K.Ishunin.
J. Appl. Spectrosc. (USA), vol.37, no.5, p.1253-6 (Nov. 1982). Translation of: *Zh. Prikl. Spektrosk. (USSR)*, vol.37, no.5, p.762-6 (Nov. 1982). [received: Sept. 1983]
Tin-activated alkaline-earth orthophosphates with the β-$Ca_3(PO_4)_2$ structure have long attracted attention on the one hand because of the major practical importance of various luminophors of this class and on the other because of features of the luminescence. One of the features of tin-activated calcium orthophosphates is that the spectrum contains two bands: the shortwave α one and the longwave β one, whose nature has not so far been defined. It has been suggested that the α and β bands are due to transitions from different excited levels of the Sn^{2+} ion. There has recently been discussion of the scope for interpreting the α and β bands of Sn^{2+} in alkaline-earth orthophosphates as A_T and A_X bands, which are the bands into which the luminescence spectrum is considered to be split as a consequence of the Jahn-Teller effect, but no definite conclusions were reached, evidently on account of deficiency in the experimental data. The authors have derived additional data on the luminescence of these phosphors by more detailed examination of the excitation and luminescence spectra. (7 refs.)

109006 Spectral investigations of the anthracene-carbazole system. N.N.Malykhina, V.A.Lisovenko.
J. Appl. Spectrosc. (USA), vol.37, no.5, p.1257-61 (Nov. 1982). Translation of: *Zh. Prikl. Spektrosk. (USSR)*, vol.37, no.5, p.766-71 (Nov. 1982). [received: Sept. 1983]
An investigation of the binary system anthracene-carbazole is of interest from several standpoints. In the first place, carbazole is one of the most widespread impurities in anthracene, which is evidently explained by the isomorphism of these molecules. But since the singlet level of carbazole is situated at a higher energy value than the singlet level of anthracene, it cannot be detected directly by spectral methods. However, carbazole may appear indirectly, for example, leading to local states. A study of the spectral properties of the anthracene-carbazole system in a wide range of concentrations is also of independent interest. This task is facilitated by the fact that the phase diagram of this system is known in the region of concentrations from 0 to 100%. For the experiments, the authors used anthracene and carbazole subjected to purification by zone melting of 100 and 150 zones, respectively. The concentration of impurities was determined according to weighed samples. An anthracene-carbazole mixture was melted in a 200 μ thick quartz cuvette. The fluorescence spectra were excited through a filter with transmission maximum in the region of 313 nm and recorded on a spectrometer with a photoelectric attachment at the temperature of liquid helium. (4 refs.)

109007 Fine structure of the bands in the low-temperature spectra of sodium uranyl acetate. V.N.Boikov, A.N.Krasovskii, D.S.Umreiko.
J. Appl. Spectrosc. (USA), vol.37, no.5, p.1277-81 (Nov. 1982). Translation of: *Zh. Prikl. Spektrosk. (USSR)*, vol.37, no.5, p.790-5 (Nov. 1982). [received: Sept. 1983]
The authors have studied the luminescence spectrum of sodium uranyl acetate at 8K under conditions of selective optical excitation, carried out close to resonance frequencies. (12 refs.)

109008 Photothermal creation of $Cu^0v_a^+$ centres and mobility of anion vacancies in X-irradiated KCl:Cu crystals. S.Zazubovich, A.Usarov, ZH.Egemberdiev (Inst. of Phys., Acad. of Sci., Tartu, Estonian SSR).
Phys. Status Solidi b (Germany), vol.118, no.2, p.789-98 (1 Aug. 1983).
Associates of Cu^0 atoms with anion vacancies v_a^+($Cu^0v_a^+$ centres) are used as luminescent detectors for the study of anion vacancy mobility in KCl crystals. It is found that near 220K, $Cu^0v_a^+$ centres may be thermally formed because of the migration of v_a^+ only to its neighbouring Cu^0 atom (i.e. the process occurs in Cu^0-v_a^+ pairs). An analogous process in $\{Cu^+$-$v_a^+\}$ pairs results in the creation of $Cu^+v_a^+$ centres. After $Cu^+v_a^+$ have trapped electrons released at the thermal destruction of Cu^0, $Cu^0v_a^+$ centres are formed. $\{Cu^0$-$v_a^+\}$ and $\{Cu^+$-$v_a^+\}$ pairs are produced at low temperatures by the transfer of an F electron onto an impurity ion in irradiation-generated $\{Cu^+$-F$\}$ and $\{Cu^{2+}$-F$\}$ pairs. If the crystal contains $Cu^-{}_a$ centres, $Cu^0v_a^+$ centres may be formed at $T > 370$K by the interaction of mobile V_F centres, produced at a thermal dissociation of Cl_3 molecular ions, with $Cu^-{}_a$ centres. It is proposed that at T<300K it is not the isolated but the 'associated' anion vacancy that can migrate. This process occurs in the field of some defects and needs a comparatively lower activation energy than the motion of isolated v_a^+. The isolated or 'free' v_a^+ which are believed to be mobile at higher temperatures, are practically absent in X-irradiated crystals at T>250K due to the interaction of v_a^+ with mobile cation vacancies or interstitial halide ions as well as due to the thermal association of v_a^+ with neighbouring lattice defects. (40 refs.)

109009 Tail-tail luminescence in amorphous silicon. B.Rauscher, H.Pfleiderer (Forschungslab., Siemens AG, Munchen, Germany), B.Bullemer.
Phys. Status Solidi a (Germany), vol.78, no.2, p.623-32 (16 Aug. 1983).
Experiments and a model calculation of the stationary photoluminescence (PL) in hydrogenated amorphous silicon are presented. The model is based on the concept of geminate recombination and considers the tunneling of the photogenerated carriers from shallow to deep localized states as a process competitive with the radiative recombination. The active energy of the temperature-dependent PL quantum efficiency is the sum of the electron-hole binding energy and of the trapping energy of one of both the charge carriers. This model allows a complete interpretation of the decrease of PL quantum efficiency, the shift of the PL spectrum towards lower photon energies, and of the increase in the FWHM with rising temperature. The long-wavelength PL (0.8 eV$\leq \hbar\omega_{PL} \leq 1.0$ eV) is found to be characteristic of the density of localized midgap states. (26 refs.)

109010 The nature of photoluminescence from plastically deformed silicon. M.Suezawa, K.Sumino (Res. Inst. for Iron, Steel & Other Metals, Tohoku Univ., Sendai, Japan).
Phys. Status Solidi a (Germany), vol.78, no.2, p.639-45 (16 Aug. 1983).
The nature of photoluminescence from plastically deformed silicon crystals is investigated from the dependences of the spectrum and intensity of the luminescence on various parameters. Besides the well established characteristic lines D1 through D4, a broad background component is found to exist in the photon energy range of 0.75 to 1.1 eV. Neither impurities nor clusters of point defects are shown to be responsible for the deformation-induced photoluminescence. Thus, dislocations are concluded to be active as radiative recombination centres. It is shown, however, that dangling bonds are not responsible for the recombination processes. Thus, the reconstructed bonds or severe distortion of the lattice at the dislocation core is thought to contribute to the radiative recombination processes occurring in a plastically deformed silicon crystal. The D1 and D2 lines seem to be related to geometrical kinks on dislocations. (13 refs.)

109011 Photoluminescence of rare-earth centers in ZnO phosphors. Vu Xuan Quang, Nguyen Quang Liem, Nguyen Cong Thanh, Truong Van Chuong, Le Thi Le Thanh (Inst. of Phys., Hanoi, Vietnam).
Phys. Status Solidi a (Germany), vol.78, no.2, p.K161-5 (16 Aug. 1983).
Trivalent rare-earth ions (RE) in II-VI phosphors show luminescence spectra which are characterized by a broad-band emission and a narrow line emission as well. It is shown that group V ions, for example N ions, can act simultaneously as charge compensations and as energy transfer agent. Obviously in the ZnO:N, RE system, the occupying of a trivalent RE ion in a bivalent substitutional Zn site is more easier than that in, for instance the ZnO:Na, Cu, RE system. Samples used were ZnO:N, Eu^{3+} powder phosphors. (15 refs.)

109012 Pressure dependence of the alexandrite emission spectrum. T.Kottke, F.Williams (Phys. Dept., Univ. of Delaware, Newark, DE, USA).
Phys. Rev. B (USA), vol.28, no.4, p.1923-7 (15 Aug. 1983).
The dependence on hydrostatic pressure of the photoluminescent spectrum of alexandrite has been measured to 40 kbar, at 300 and 167K. The R_1 and R_2 lines red shift linearly 0.27 ± 0.01 and 0.33 ± 0.1 Å/kbar, the same for both temperatures. Narrowing of the R lines with pressure is observed. The phonon sidebands are blue shifted with pressure. By analysis of these spectral shifts the authors calculate the anharmonicities of the $^4A_2$ and ^2E states and explain the line narrowing. Thus from these analyses they propose that the linear dependency of the R-line transition energies on hydrostatic pressure results from anharmonic effects on the zero-point levels of the $^4A_2$ and ^2E states, for Cr^{3+}-doped materials in general. (13 refs.)

109013 The nature of luminescent transitions of the main U^{6+} center in NaF. A.Lupei, V.Lupei (Central Inst. of Phys., Bucharest, Rumania).
Rev. Roum. Phys. (Rumania), vol.28, no.4, p.367-70 (1983).
The lowest electronic transitions in the excitation spectra of the main luminescent U^{6+} center in NaF are discussed in terms of a charge transfer transition, within a tetragonal C_{4v}, UO_5F^{5-} complex. The lines 5380 Å, 5528 Å, 5636 Å, the last ones observed in luminescence spectra too, are assigned to a $\gamma_7 \rightarrow \gamma_7$ charge transfer transition. The excited states associated to this charge transfer transition have A_1, A_2 and E symmetry, as determined experimentally for the lowest excited levels. (13 refs.)

109014 Polariton luminescence and additional boundary conditions: comparison between theory and experiment. F.Askary, P.Y.Yu (Dept. of Phys., Univ. of California, Berkeley, CA, USA).
Solid State Commun. (USA), vol.47, no.4, p.241-6 (July 1983).
Polariton luminescence spectra in semiconductors have been calculated as a function of temperature and impurity trapping rates using a two branch polariton model. Typically, the theoretical spectra show two structures: a peak near the transverse exciton energy and a shoulder near the longitudinal exciton energy. While the lower energy peak is relatively insensitive to the choice of additional boundary conditions (ABC), the higher energy shoulder strongly depends on (ABC). The theoretical curves obtained with Pekar's ABC are in quantitative agreement with experimental spectra reported in CdS, CdSe and CuCl. However, significant discrepancies between theory and experiment are found in GaAs and ZnTe. (23 refs.)

109015 Tunnelling contribution in non-radiative processes. R.Englman (Soreq Nuclear Res. Centre, Yavne, Israel), A.Ranfagni, D.Mugnai, A.Agresti.
Solid State Commun. (USA), vol.47, no.9, p.723-6 (Sept. 1983).
A semiclassical formalism, already introduced to treat non-radiative processes in multidimensional spaces, has been extended to compute total non-radiative transition rates. A simple approximate analysis results in simple formulae which discriminate between quantum-tunnelling contributions and classical ones. Applications to diffusion processes of vacancies in solids are considered. (20 refs.)

109016 GaAs surface oxidation-related photoluminescence transients. H.Booyens, J.H.Basson, A.W.R.Leitch, M.E.Lee, C.M.Stander (Nat. Inst. for Materials Res., Council for Sci. & Industrial Res., Pretoria, S Africa).
Surf. Sci. (Netherlands), vol.130, no.2, p.259-68 (Aug. 1983).
Evidence is presented for the involvement of surface oxidation phenomena in the photoluminescence response obtained on GaAs (110) surfaces. By using high intensity HeNe laser illumination on freshly cleaved (110) n-type GaAs surfaces, room temperature photoluminescence transients are observed having magnitudes determined by excitation intensity. The observed transients are in excess of the steady state photoluminescence signal on surfaces exposed to normal ambient air conditions. A model based on photodesorption and photoadsorption processes, is proposed to explain this phenomenon. (20 refs.)

78.60F Electroluminescence

109017 Measurement of electroluminescence spectra of Ga phosphide p-n junctions with time resolution. A.M.Demchenko.
Optoelektron. & Poluprovodn. Tekh. (USSR), no.1, p.36-9 (1982). In Russian.
A unit for measuring the title spectra is described, and the spectra are measured over a nitrogen concentration range of 8.10^{17} to 7.10^{18} cm^{-3} and over the temperature range of 100-400K. It is established that with increase in nitrogen concentration the maximum radiation at room temperature is displaced into the long wave region by an amount equal to the energy of the LO phonon. With increase in current density from 5 to 100 $A.cm^{-2}$ the quantum radiation yield in the green region of the spectrum is increased from 0.05 to 0.3%. (9 refs.) *N.F.S.*

109018 A study of the luminescent and electrical characteristics of films of ZnS doped with Mn. A.J.Warren, C.B.Thomas, H.S.Reehal, P.R.C.Stevens (School of Appl. Phys. & Phys. Electronics, Univ. of Bradford, Bradford, England).
J. Lumin. (Netherlands), vol.28, no.2, p.147-62 (May-July 1983).
The preparation of films of ZnS by radio-frequency sputtering and also the doping with manganese by either co-sputtering or ion-beam implantation has been described. The brightness of ZnS:Mn films doped by both techniques have been compared. Also concentration quenching has been examined. In addition the conditions for preparing ZnS films on ITO substrates which are free of pin-holes have been given. Space-charge limited currents, defined by thickness dependence, have been observed prior to the onset of electroluminescence. A brief description is presented also of the behaviour of DC pulsed devices of ITO/ZnS:Mn/Al devices during electroluminescent operation. (14 refs.)

109019 Electroluminescence in In-ZnSe:Cu-ZnSe(s)-Au structures. W.Bala, F.Firszt, H.J.Lozykowski (Inst. of Phys., Nicolas Copernicus, Torun, Poland).
J. Lumin. (Netherlands), vol.28, no.2, p.203-15 (May-July 1983).
The electroluminescent properties of In-ZnSe:Cu-ZnSe(s)-Au structures have been studied in the temperature range from 27 to 300K. The spectrum of the forward-biased diodes at 27K consists of emission lines due to the recombination of bound excitons, an associated donor-acceptor pair band with LO-phonon replicas and a deep level emission (green and red bands). At room temperature only the red band was observed. The time-resolved spectra (TRS) of the deep levels emission have also been investigated. (27 refs.)

109020 The effect of self radiation on the aging of zinc-sulfide phosphors. B.A.Kovalev.
Svetotekhnika (USSR), no.7, p.15-16 (1983). In Russian.
The process of the aging of zinc-sulfide phosphors exposed to self radiation is studied. The reabsorption of the self radiation is shown to affect this process. A decrease in the electroluminescence brightness drop rate is explained by a model accounting for copper ion electrodiffusion and increased voltage within the phosphor grains. A mechanism of photoinhibited impurity diffusion is assumed to take place. (6 refs.)

Exciton-enhanced double injection currents in tetracene crystals .... See Entry 108301

78.60H Cathodoluminescence, ionoluminescence

109021 Cathodoluminescent efficiency of $Y_3Al_5O_{12}$ and $YAlO_3$ single crystals in dependence on Ce^{3+} and other dopants concentration. R.Autrata, P.Schauer, J.Kvapil, J.Kvapil (Inst. of Sci. Instruments, Czechoslovak Acad. of Sci., Brno, Czechoslovakia).
Cryst. Res. & Technol. (Germany), vol.18, no.7, p.907-13 (1983).
The content of Ce^{3+} ions in the investigated single crystals grown under reducing conditions is limited by a low value of the distribution coefficient. This distribution coefficient decreases sharply with increasing concentration of Ce^{3+} ions in a melt. Cathodoluminescent efficiency rises with increasing Ce^{3+} concentration up to a certain state of saturation. At higher concentrations of Ce^{3+} ions emission from activator centres is dominant, while at lower concentrations defect centres play an important part. Iron acts as a strong quenching centre, especially in the $YAlO_3$ lattice. Nd, Ir, Fe, Ti, Cr centres exhibit a high quenching effect too. A trace amount of Mo enhances cathodoluminescent efficiency. (5 refs.)

109022 Emission and transmission cathodoluminescence analysis of InGaAsP/InP double heterostructures emitting at 1.3 and 1.6 micron. M.Cocito (CSELT, Torino, Italy), C.Papuzza, F.Taiariol.
CSELT Rapp. Tec. (Italy), vol.11, no.4, p.293-7 (Aug. 1983).
An investigation on the crystallographic defects and the surface morphology of InGaAsP/InP liquid phase epitaxy (LPE) doubleheterostructure (DH) is reported. A combination of emission cathodoluminescence (ECL), transmission cathodoluminescence (TCL), Si and Ge detectors at various beam energies allowed the identification of crystallographic defects on different layers in complete DHs with a simple and nondestructive technique. A preliminary work on InP substrates and on single layer structures enabled us to understand the main cathodoluminescence (CL) contrast mechanisms and to emphasize some basic rules for the interpretation of the complete DH images. (4 refs.)

109023 Thermally induced changes in the cathodoluminescence image of deformed MgO. J.Llopis, C.Ballesteros (Dept. de Fisica del Estado Solido, Univ. Complutense, Madrid, Spain), J.Piqueras, A.Remon, R.Gonzalez.
Phys. Status Solidi a (Germany), vol.78, no.2, p.679-84 (16 Aug. 1983).
The effect of annealing of the cathodoluminescence (CL) from deformed MgO single crystals has been investigated. Annealing at 1200°C for a short time changes the bright slip bands into dark bands and also produces CL rosettes in indented crystals. The behaviour is attributed to annihilation and diffusion of point defects responsible for the CL emission. (16 refs.)

78.60K Thermoluminescence

109024 Thermoluminescence studies in KBr_xI_{1-x} mixed crystals. P.Veeresham, U.V.Subba Rao, V.Hari Babu (Dept. of Phys., Osmania Univ., Hyderabad, India).
Cryst. Res. & Technol. (Germany), vol.18, no.7, p.939-49 (1983).
Thermoluminescence (TL) studies have been carried out in KBr, KI, and in different compositions of KBr_xI_{1-x} mixed crystals as a function of X-irradiation time. The TL glow peaks have been analysed and the trap depths and frequency factors have been calculated for different compositions. The complex TL peaks observed in these crystals were isolated by using thermal cleaning technique. The various glow peaks observed in these crystals were attributed to native impurities, first stage and second stage colour centres and the results have been discussed. (11 refs.)

109025 Trap distribution analysis for thermoluminescence of $CaSO_4$:Dy. J.K.Srivastava, S.J.Supe (Div. of Radiological Protection, Bhabha Atomic Res. Centre, Trombay, Bombay, India).
J. Phys. D (GB), vol.16, no.9, p.1813-18 (14 Sept. 1983).
The trap distribution analysis of $CaSO_4$:Dy has been carried out using a fractional-glow technique. It shows that the TL process in $CaSO_4$:Dy involves quasi-continuous distribution of traps with activation energies ranging from 1.15 to 2.39 eV in the 340-370K glow-temperature range. The trap spectrum of $CaSO_4$:Dy reveals that the activation energies are distributed in a number of groups, with a prominent group, linked with the 495K dosimetric peak, peaking at around 1.40 eV. (11 refs.)

109026 Build-up of CaF_2 thermoluminescence excited by high energy X-rays. S.Costa (Istituto di Fisica Superiore Univ. Torino, Torino, Italy), A.Delunas, V.Maxia, G.Spano.
J. Lumin. (Netherlands), vol.28, no.2, p.217-20 (May-July 1983).
Experiments have been performed on the buildup of CaF_2 thermoluminescence excited by penetrating X-rays, thus avoiding effects caused by the sample absorption. The initial part of the buildup curve shows superlinear behaviour which can be explained by the presence of two kinds of recombination levels. (6 refs.)

109027 Optical absorption and thermoluminescence of KCl single crystals coloured under DC fields. A.Subrahmanyam (Dept. of Phys., Indian Inst. of Technol., Madras, India).
Phys. Status Solidi a (Germany), vol.78, no.2, p.665-70 (16 Aug. 1983).
The optical absorption and thermoluminescence of KCl single crystals X-irradiated at 300 and 373K are studied in presence of large DC fields (0 to 22 kV/cm). With DC field the F band peak shifts to the higher frequency side and the overall colour centre concentration is observed to increase. The shift in F band is attributed to a shrinkage in the lattice parameter (at the dislocation region) due to the mobile anion impurity experiencing the applied field. The preferential movements of charges may decrease the rate of recombination of the generated carriers resulting in an increase in colour centre concentration. An attempt is made to analyse these data. (11 refs.)

109028 Thermoluminescence of Z_3 centres in X-irradiated Ca-doped KCl crystals. J.Manam (Dept. of Phys., Indian Inst. of Technol., Kharagpur, India), R.K.Gartia, V.V.Ratnam.
Phys. Status Solidi a (Germany), vol.78, no.2, p.685-8 (16 Aug. 1983).
The formation of Z_3 centres in Ca-doped crystals is studied using thermoluminescence as the tool. By an expeditious choice of the temperature of X-irradiation and the time of post-irradiation F-bleaching the centers responsible for the occurrence of the glow peak at 326K are identified to be Z_3 centres. 196K appears to be very a favourable suitable temperature for the formation of Z_3 centers. (10 refs.)

78.65 OPTICAL PROPERTIES OF THIN FILMS

109029 Infrared transmission spectra of $CuInSe_2$ thin films. H.Neumann, H.Sobotta, V.Riede, B.Schumann, G.Kuhn (Sektion Phys. und Sektion Chem., Karl-Marx-Univ., Leipzig, Germany).
Cryst. Res. & Technol. (Germany), vol.18, no.7, p.K90-2 (1983).
The optical transmission spectra were recorded at room temperature with unpolarised radiation at normal incidence in the wavenumber range $\bar{\nu}=50-300$ cm^{-1} where the fundamental lattice modes of $CuInSe_2$ are expected. There are two strongly pronounced minima at $\bar{\nu}=213$ cm^{-1} and $\bar{\nu}_2=206$ cm^{-1} and a broad weaker minimum at $\bar{\nu}_3=168$ cm^{-1}. Within the error limits of $\Delta\bar{\nu}_1=\Delta\bar{\nu}_2=\pm 2$ cm^{-1} and $\Delta\bar{\nu}_3=\pm 5$ cm^{-1} in the frequency determination the position of these minima was independent on the thickness of the substrate and the film. Therefore, the authors can be sure that they are caused by the lattice vibrations of $CuInSe_2$ and can be identified with transverse optical mode frequencies. (18 refs.)

109030 Electrooptic effect in anodic Nb_2O_5 films. Shen Wenjiang (Shanghai Inst. of Railway Technol., Shanghai, China).
Acta Opt. Sin. (China), vol.3, no.4, p.344-50 (1983). In Chinese.
The measurement and experimental result of the electrooptic effect in anodic Nb_2O_5 films are presented. It has been found that dependences of the change in indices on the field are different from those reported in previous papers. The power is 2 at higher field and 1.63 at lower field. Some hysteresis, but no permanent change in indices was observed. (13 refs.)

109031 Maximum statistical increase of optical absorption in textured semiconductor films. H.W.Deckman, C.B.Roxlo, E.Yablonovitch (Exxon Res. & Engng. Co., Linden, NJ, USA).
Opt. Lett. (USA), vol.8, no.9, p.491-3 (Sept. 1983).
Complete statistical randomization of the direction of propagation of light trapped in semiconductor films can result in a large absorption enhancement. The authors have employed a calorimetric technique, photothermal deflection spectroscopy, to monitor the absorption of *a*-SiH_x films textured by the natural lithography process. The observed enhancement factors as high as 11.5, are consistent with full internal phase-space randomization of the incoming light. (8 refs.)

109032 Irradiation-induced photodarkening in As-Se-Cu amorphous films. M.M.Hafiz (Phys. Dept., Assiut Univ., Assiut, Egypt), H.M.Shafey, A.M.Hafez, M.Dongol.
Phys. Status Solidi a (Germany), vol.78, no.2, p.449-55 (16 Aug. 1983).
Irradiation-induced photodarkening in evaporated $As_{30}Se_{60}Cu_{10}$ films is studied. The transmission spectra are shifted towards longer wavelengths after irradiation. Increasing the irradiation flux seems to have negligible effect on the total decrease in the spectral transmission of these films. The change in transmission is found to increase with increasing chalcogenide film thickness. A quantitative description of the photodarkening effect is given. The calculations show that the photodarkening effect depends only on the value of the absorption coefficient regardless of its spectral distribution. The study of the photodarkening kinetics indicates that the latent darkening centres are directly proportional to the chalcogenide film thickness. The optical behaviour of the heat treated films after irradiation is also studied. The results are discussed on the basis of rearrangement of the constituent atoms which takes place within a short-range order of the network. (20 refs.)

109033 Optical and electrical properties of laser-synthesized CdTe. L.Baufay, A.Pigeolet, R.Andrew, L.D.Laude (Univ. de l'Etat, Mons, Belgium).
Laser-Solid Interactions and Transient Thermal Processing of Materials, Boston, MA, USA, 1-4 Nov. 1982 (New York, USA: Elsevier 1983), p.665-70
Optical and electrical characterization of CdTe synthesized by laser irradiation of a multilayer film of alternate Cd and Te is achieved. Optical absorption measurements evidence the good quality of these films and show that they have behaviour comparable to the single crystal. The influence of the irradiation conditions on the electrical properties of such CdTe films is discussed; they are compared to the single crystal from the point of view of resistivity. It is shown that it is possible to prepare by this means samples devoid of impurity states in the middle of the forbidden gap. Finally, the ohmicity of Au, Al, Cr, ITO nonirradiated Cd/Te sandwich contacts is tested. (22 refs.)

78.70 OTHER INTERACTIONS OF MATTER WITH PARTICLES AND RADIATION

109034 Directional Compton profiles and the electron density distribution in iron. A.J.Rollason, R.S.Holt, M.J.Cooper (Dept. of Phys., Univ. of Warwick, Coventry, England).
J. Phys. F (GB), vol.13, no.9, p.1807-19 (Sept. 1983).
The [100], [110] and [111] directional Compton profiles and their reciprocal form factors (*B* functions) have been deduced from Compton scattering measurements on single crystal slices of iron with ^{198}Au 412 keV gamma radiation. The accuracy of the individual profiles is sufficient not only to detect the small asphericity in the electron momentum density but also to discriminate between APW and LCAO band-structure models. In general terms the LCAO calculations with a Gaussian basis describe the momentum density better, although, in common with studies of other transition metals, the asphericity is still overestimated. Inspection of the reciprocal form factor reveals aspects of the density distribution not adequately by either model. (28 refs.)

109035 Density-functional theory of the Compton profiles of beryllium metal. G.E.W.Bauer, J.R.Schneider (Hahn-Meitner-Inst. fur Kernforschung, Berlin, Germany).
Solid State Commun. (USA), vol.47, no.9, p.673-6 (Sept. 1983).
A first-principles momentum density correlation correction functional in the local density approximation is shown to improve the agreement between experimental Compton profiles of beryllium and recent band structure calculations. (39 refs.)

78.70B Positron annihilation

(see also 71.65 Positron states)

109036 A study of positron annihilation in the bulk and on the surface of Pd-Si and Pd-Si-Cu amorphous alloys. Ch.Abrayev, I.Ya.Dekhtyar, E.G.Madatova, M.M.Nishchenko (Inst. of Phys. of Metals, Acad. of Sci., Kiev, Ukrainian SSR).
Phys. Met. (GB). Translation of: Metallofizika, Kiev (USSR), vol.4, no.3, p.525-30 (1982). [received: Aug. 1983]
Positron annihilation in the bulk and on the surface of Pd-Si and Pd-Si-Cu alloys has been used to study the alloy structure in the crystalline and amorphous phases. The changes in bulk annihilation observed on transition to the amorphous phase are interpreted as being due to a different mechanism of the charge transfer from one alloy constituent atom to another. The surface changes following the transition are attributed to the charge transfer from one species of surface atoms to another, and to the effect of adsorption on the composition of the alloy surface layer. (3 refs.)

109037 Positron study of Nb-Mo alloys. N.Shiotani, T.Okada, H.Sekizawa (Inst. of Phys. & Chem. Res., Saitama, Japan), T.Nakamichi.
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2858-61 (Aug. 1983).
Angular correlations of positron annihilation radiation on $Nb_{80}Mo_{20}$ and $Nb_{50}Mo_{50}$ are measured. The electron-positron pair momentum distributions are calculated using the rigid band model based on the band structure of pure Nb. Most of the experimental features are reproduced and explained by a simple physical picture that the extra valence electrons from Mo fill the hole region in the momentum space. It is found that there exist well defined Fermi surfaces even in the most concentrated alloy of this system. (9 refs.)

109038 Precise positron lifetime measurements in indium. W.Puff, P.Mascher, P.Kindl, H.Sormann (Inst. fur Kernphys., Tech. Univ. Graz, Graz, Austria).
Phys. Status Solidi b (Germany), vol.118, no.2, p.799-803 (1 Aug. 1983).
The positron lifetime is measured in polycrystalline indium in the temperature range between 80 and 420K. The data show a pronounced prevacancy effect which is fairly well approximated by a straight line. The results suggest transient dilatation trapping rather than metastable self-trapping. The occurrence of this effect has some influence on the values deduced for the monovacancy formation enthalpy. In the temperature range below 180K detrapping of positrons cannot be ruled out. (23 refs.)

109039 Positron angular correlation in uncoloured and neutron irradiated LiF and LiF:OH. D.N.Popov, N.M.Nancheva, B.N.Zlatov, G.P.Georgiev (Dept. of Phys., Tech. Univ. 'Angel Kunchev', Russe, Bulgaria).
Phys. Status Solidi b (Germany), vol.118, no.2, p.K129-32 (1 Aug. 1983).
Reports positron angular correlation in uncoloured and neutron irradiated LiF and LiF:OH. Pure and OH^- doped single crystals have been used in the experiments. The concentration of the OH^- centers in LiF:OH was about 10^{19} cm^{-3}. The coloration has been made by neutron irradiation in a reactor channel. In all cases the irradiation dose was 10^{16} neutrons/cm^2. The angular distribution of the annihilating photons (ADAP) was measured using a conventional slit arrangement. (6 refs.)

109040 Microstructure and imperfections of glassy and glass-ceramic telluride semiconductors on the basis of positron annihilation. B.V.Kobrin, R.M.Kupriyanova, V.S.Minaev, E.P.Prokopiev, V.P.Shantarovich (Inst. of Chem. Phys., Moscow, USSR).
Phys. Status Solidi a (Germany), vol.78, no.2, p.385-9 (16 Aug. 1983).
The microstructures of glassy and glass-ceramic telluride semiconductors are studied by the positron annihilation technique. The validity of some structural models for such materials is analysed. An identification technique of defects (positron trapping centers) in these semiconductors is proposed. Quantitative estimations of defect concentrations are made. Additional evidence for the co-existence of two phases in the Si-Te system over certain ranges of Te concentrations is presented. The characteristic sizes of microcrystalline inclusions in Ge-Te and Si-Te glass-ceramics are estimated. (14 refs.)

109041 Achievements and perspectives in positron physics. R.I.Campeanu (Univ. Babes-Bolyai, Cluj-Napoca, Rumania).
Stud. & Cercet. Fiz. (Rumania), vol.35, no.7, p.601-22 (1983). In Rumanian.
After 50 years of existence, positronics develops today as a rapidly expanding field. This report provides an introductory survey for readers unfamiliar with positron physics, which stresses the wide applicability of positron annihilation techniques. New experimental tools and powerful computers now give physicists good insights into the behaviour of positrons in gases, liquids and solids. On the other hand, the use of positron annihilation techniques in related sciences, like chemistry, astrophysics, biology and medicine, has already passed the pioneering stage. (170 refs.)

109042 Positron studies of Ti-based alloys irradiated by neutrons. I.Ya.Dekhtyar, Sh.Sh.Ibragimov, M.I.Bitembaev, A.I.Kupchishin, K.M.Mukashev, R.G.Fedchenko.
Ukr. Fiz. Zh. (USSR), vol.28, no.8, p.1214-18 (Aug. 1983). In Russian.
Neutron irradiation of Ti-Al alloys leads to a change in positron annihilation parameters. Low-temperature stage due to disappearance of vacancies and a

stage caused by disappearance of dislocation-type defects are observed in isochronal annealing curves of the irradiated alloys. (8 refs.)

109043 Defect structures close to the surface in metals investigated by slow positrons. W.Triftshauser, G.Kogel (Hochschule der Bundeswehr Munchen, Neubiberg, Germany).
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.15-18
A new system has been developed to produce monoenergetic positrons of variable energy. The energy range available at present is between 100 eV and 28 keV. This positron beam can be used to investigate defects and defect structures close to the surface in metals and alloys. The Doppler broadening technique of the annihilation radiation is applied for these investigations. (8 refs.)

109044 Positron annihilation in thermal equilibrium on pure and carbon doped α-iron. L.De Schepper (Materials Phys. Group, Limburgs Univ. Centrum, Diepenbeek, Belgium), D.Segers, G.Knuyt, J.Van Oppen, L.Dorikens-Vanpraet, M.Dorikens, L.Stals, P.Moser.
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.508-11
Positron annihilation measurements in thermal equilibrium on extremely pure α-iron (total interstitial impurity content $\sim$5 at.ppm) and on 50 at.ppm carbon doped α-iron are presented. In pure iron, no positron trapping is observed in the ferromagnetic state. Consequently, the vacancy formation enthalpy in this state cannot be determined from the analysis of equilibrium data. However, in carbon-doped iron trapping is already observed at 700°C. This is interpreted in terms of localization of the positron at other sites than single vacancies, presumably carbon-vacancy pairs. (7 refs.)

109045 Measurement of the integrated reflection coefficients of gypsum, quartz, and mica crystals for soft X-rays. A.L.Zapysov, I.M.Izrailev, V.A.Podgornov, N.A.Kharvonin.
Instrum. & Exp. Tech. (USA), vol.25, no.6, pt.2, p.1504-7 (Nov.-Dec. 1982). Translation of: *Prib. & Tekh. Eksp. (USSR)*, vol.25, no.6, p.170-2 (Nov.-Dec. 1982).
Presents the results of measurements of the integrated reflection coefficients of flat crystals of gypsum [(020) plane], quartz [(10$\bar{1}$0) plane], and mica [(002) plane] for X-rays with a quantum energy of 1.25-2.31 keV. The measurements were made in a divergent X-ray beam of K_α-radiation of the elements Mg, Al, Si, and S and a fixed crystal. The experimental results are compared with calculated values. (10 refs.)

109046 Study of the behaviour of Al-Zn alloys by SAXS in the temperature range of the instable solid solution. G.Wendrock (Sektion Math./Phys., Padagogischen Hochschule Halle (Saale),,Germany). Halle.
Phys. Status Solidi a (Germany), vol.78, no.2, p.497-506 (16 Aug. 1983).
During cooling from the homogeneous region the structural changes of Al-Zn alloys in the range from 10 at.% up to 60 at.% Zn are observed by means of SAXS. Using a special method of investigation, typical courses of the matrix scattering (background scattering) with respect to the temperature are obtained with characteristic points and ranges. The behaviour of the matrix scattering intensity shows that already about 30K above the maximal temperature of the miscibility gap at about 39 at.% Zn an 'anomalous' concentration fluctuation is formed. The fluctuations increase with decreasing temperature and obviously represent a gradual transition into the inhomogeneous state. The characteristics of the matrix scattering allow one to define a line in the Al-Zn phase diagram which is due to the starting temperature of homogeneous nucleation. They also indicate points of the metastable as well as stable phase boundaries. Calculations based on well known models prove the concept that the behavior of the matrix scattering is influenced by the concentration fluctuations depending on temperature. (27 refs.)

78.70D X-ray absorption and absorption edges

109047 Conductivity measurement of an X-ray absorption spectrum: Re L_{III} near-edge structure of $Re_2(CO)_{10}$ in 2,2,4-trimethylpentane. T.K.Sham (Dept. of Chem., Brookhaven Nat. Lab., Upton, NY, USA), S.M.Heald.
J. Am. Chem. Soc. (USA), vol.105, no.15, p.5142-3 (27 July 1983).
The authors report the measurements of an X-ray absorption spectrum by means of X-ray photoconductivity in a hydrocarbon solution. $Re_2(CO)_{10}$ in 2,2,4-trimethylpentane has been used for these measurements. The main objective of the report is to demonstrate the feasibility of this technique and its potential applications. (14 refs.)

109048 EXAFS study of Ni-Cl bonding in Ni(11) aqueous solutions at increasing Cl^-/Ni^{2+} ratios. G.Licheri, G.Paschina, G.Piccaluga, G.Pinna (Istituto di Chimica Fisica e Industriale, Univ. di Cagliari, Cagliari, Italy).
J. Chem. Phys. (USA), vol.79, no.5, p.2168-71 (1 Sept. 1983).
Three aqueous solutions of $NiCl_2$ with a constant concentration in Ni^{2+} and increasing Cl^-/Ni^{2+} ratios were examined by EXAFS spectroscopy. Fourier transforms of the experimental data give evidence of the increasing complex formation betwen Ni^{2+} and Cl^- ions. A quantitative analysis of this phenomenon is also attempted, based on the interpretation of Fourier filtered EXAFS spectra. (27 refs.)

109049 Application of synchrotron radiation to EXAFS and SEXAFS. H.Oyanagi (Electrotech. Lab., Ibaraki, Japan), T.Ota.
J. Vac. Soc. Jpn. (Japan), vol.26, no.3, p.219-45 (1983). In Japanese.
The most fundamental and important theme in the study of substances is examination of their microstructure. In the X-ray absorption of a substance, a fine oscillatory structure appears over a wide absorption spectrum range. This phenomenon is referred to as the extended X-ray absorption fine structure (EXSFS). It has been known for a long time that this phenomenon is related to the structure of the substance. In this review paper, new information is presented around analysis methods and experimental techniques of EXAFS. The description includes: (1) the basic formula for EXAFS; (2) problems in EXAFS theory; (3) surface EXAFS; (4) EXAFS experimental methods; (5) soft X-ray optical systems; (6) analysis methods of EXAFS; and (7) the application of EXFAS to chemistry, living things and solid surfaces. (79 refs.) *K.B.*

109050 On the chemical shifts of the K-absorption discontinuity of copper in some of its systems. B.Jagannatha Rao, A.R.Chetal (Dept. of Phys. & Maths., Indian School of Mines, Dhanbad, India).
Phys. Status Solidi b (Germany), vol.118, no.2, p.551-5 (1 Aug. 1983).
The K-absorption edge of copper in different copper systems is studied using a 40 cm Cauchois-type bent crystal spectrograph. It is observed that the K-edge shifts towards the high-energy side in all the copper systems under study (except in Cu_2O). This indicates that the copper ion behaves as a cation (except in Cu_2O). The shift is correlated with the partial charge on an absorbing ion in the system and the correlation is found to be linear. The partial charge on the copper ion in the systems chalcopyrite, copper perchlorate, and copper fluoborate is determined from the plot of the chemical shift versus the partial charge. (21 refs.)

109051 Anisotropic absorption of unpolarized X-radiation in copper-intercalated niobium disulfide. W.Thulke, R.Haensel, P.Rabe (Inst. fur Experimentalphys., Univ. Kiel, Kiel, Germany).
Phys. Status Solidi a (Germany), vol.78, no.2, p.539-45 (16 Aug. 1983).
Unpolarized X-rays from a conventional rotating anode X-ray generator are used to investigate the local environment of Cu in single crystals of the intercalation compound $Cu_{0.5}NbS_2$ by analysis of the extended X-ray absorption fine structure (EXAFS) above the Cu K-absorption edge. The anisotropy of the EXAFS allows the separation of two slightly different bond lengths between Cu and the surrounding S atoms. Measurements at low temperature indicate a substantial decrease of the van der Waals gap height and small displacements of the atoms parallel to the sandwich layers of the host crystal. (12 refs.)

109052 *L*-edge X-ray absorption spectra of γ- and α-cerium. B.Lengeler (Inst. fur Festkorperforschung, Julich, Julich, Germany), G.Materlik, J.E.Muller.
Phys. Rev. B (USA), vol.28, no.4, p.2276-8 (15 Aug. 1983).
The L absorption spectra of γ- and α-Ce have been measured. The L_2 and L_3 spectra of both systems show white lines, but α-Ce exhibits an additional peak 9 eV above the white line. In a mixed-valence model α-Ce has a ratio $[Ce^{3+}]$ to $[Ce^{4+}]$ of about 0.8 to 0.2. However, this interpretation is in conflict with Compton scattering. The measured extended X-ray-absorption fine-structure (EXAFS) spectra of α-Ce allow only for one value E_0 (zero of photoelectron energy). It is an open question why only one value E_0 is observed in the EXAFS of mixed-valent systems. (15 refs.)

109053 Extended X-ray absorption fine structure of electron-irradiated dilute aluminium alloys. W.Weber, H.Peisl (Sektion Phys., Ludwig-Maximilians Univ., Munchen, Germany).
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.368-71
The EXAFS technique has been applied for the first time to study electron irradiation produced self-interstitials trapped at impurities in dilute Al alloys. During an isochronal annealing procedure the recovery of two defect structures has been observed. Possible models for the defect impurity structure are discussed. (8 refs.)

109054 X-ray spectra and binding energies of atoms in a solid. V.V.Nemoshkalenkio, V.P.Krivitskii, A.V.Melezhik (Inst. of Phys. of Metals, Acad. of Sci., Kiev, Ukrainian SSR).
Phys. Met. (GB). Translation of: Metallofizika, Kiev (USSR), vol.4, no.3, p.442-60 (1982). [received: Aug. 1983]
Semiempirical formulas are suggested for calculating the energies of formation for the alloys and compounds of 3d and 4d metals and the local binding energies of constituent atoms in the crystal lattices of these compounds. Since the bonds in a crystal are created by the valence electrons of atoms constituting the crystals and since direct X-ray emission and X-ray photoelectron spectroscopy methods are most suitable for studying the energy distribution of valence states, it is useful to establish a relationship between the parameters of X-ray emission of X-ray photoelectron spectra and the energy of formation of the crystal. The calculation results agree within ±25% with the energies of formation determined experimentally. (44 refs.)

109055 X-ray emission spectra and electron structure of Ni and Fe impurity atoms in dilute copper-base solid solutions. V.R.Galakhov, E.Z.Kurmaev, A.V.Postnikov, V.I.Anisimov, V.A.Gubanov (Inst. of Chem., Ural Sci. Centre, Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.104-9 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
X-ray emission spectroscopy was used to study Cu-Fe and Cu-Ni alloys with the minimum impurity concentrations of 0.65 at.% Ni and 1.4 at.% Fe. An increase in the impurity concentration increased the width of the L_α spectrum of nickel and iron. A calculation relating to $NiCu_{12}$ and Ni_2Cu_{18} clusters, carried out by the X_α scattered-wave method with k-dependent boundary conditions, was used to interpret this broadening effect as the result of interaction between impurities. (16 refs.) *A.T.*

109056 Polarized ZnK- and OK-emission bands of ZnO. G.Drager (Sektion Phys., Martin-Luther-Univ., Halle-Wittenberg, Germany), R.Wippermann, O.Brummer, A.Simunek.
Phys. Status Solidi b (Germany), vol.118, no.2, p.K113-16 (1 Aug. 1983).
Presents calculations and measurements of the polarized ZnK-and OK-emission bands of ZnO. Only the polarized spectra contain necessary information to distinguish the various details in the electronic structure of this compound. (6 refs.)

109057 Proton-induced L-shell X-ray emission cross-sections of elements with $24 \leq Z_2 \leq 50$ for projectile energies between 30 and 350 keV. G.Kreysch, H.Kerkow (Sektion Phys., Humboldt-Univ. zu Berlin, Berlin, Germany), R.I.Bogdanov, V.P.Petukhov, E.A.Romanovskii.
Phys. Status Solidi a (Germany), vol.78, no.2, p.507-25 (16 Aug. 1983).
Total L-X-ray emission cross sections are measured for proton bombardment of thin and thick targets in a wide range of elements. The results are compared with the PWBA theory. The introduction of corrections with respect to the Coulomb deflection of the particles and to the change of the binding energy of the target electrons improves the agreement between the calculated and measured results. It is established within the experimental error that the parametrized cross section for constant reduced projectile velocities does not depend on the target atomic number. (13 refs.)

109058 Electron correlation and hole localization in photon-stimulated ion desorption from solid N_2, CO, and C_2H_2. R.A.Rosenberg, V.Rehn, A.K.Green, P.R.LaRoe (Michelson Lab., Naval Weapons Center, China Lake, CA, USA), C.C.Parks.
Phys. Rev. Lett. (USA), vol.51, no.10, p.915-18 (5 Sept. 1983).
Results of photon-stimulated ion-desorption measurements from solid N_2, CO, and C_2H_2 are presented in the photon energy range $17<h\nu<35$ eV. The photon energy dependence of the ion yields illustrates the importance of electron correlation in desorption. On the surface of solid N_2, charge localization on the nitrogen atom nearest the surface causes the N^+ spectral yield to differ from the N^+ yield from gaseous N_2 and to resemble the O^+ yield from CO. The effect of hole migration on desorption from physisorbed systems is discussed. (21 refs.)

79.20F Electron impact: Auger emission

109059 Auger spectroscopy investigations of various types of impregnated cathodes. D.Brion, J.C.Tonnerre, A.M.Shroff (Thomson-CSF Electron Tube Div., Boulogne-Billancourt, France).
Appl. Surf. Sci. (Netherlands), vol.16, no.1-2, p.55-72 (May-June 1983). (3rd Tri-Service Cathode Workshop, Fort Monmouth, NJ, USA, 23-26 March 1982).
The formation of a complete oxygen and barium monolayer on a tungsten surface has been followed by Auger spectroscopy. At 1300K, the coverage for an S-type cathode is approximately half of a monolayer. The surface composition and the state of oxidation of barium are studied and their variations are also observed as a function of the temperature on new cathodes and on cathodes after long operation time. The decrease of surface barium concentration and the important increase in the oxidation of barium lead to an increse of the work function. Between 1100 and 1500K, the activation energy for the rate of coverage variation of barium is relatively low (0.15 eV). It has been found that when aluminum is present at the surface of impregnated cathodes, it modifies the chemical environment of the barium atoms and leads frequently to the increase of barium coverage. During activation of M-type cathodes, tungsten diffuses towards the surface. For osmium films having a thickness between 3000 and 15000 Å, the surface composition after activation is near to 35% tungsten. The barium concentration is 20% higher compared to an S-type cathode while the oxygen concentration is slightly lower. The oxidation state of barium is about the same for both cathode types. (23 refs.)

109060 Interatomic Auger analysis of the oxidation of thin Ba films. I. Characterization of the low energy Auger spectrum. G.A.Haas, C.R.K.Marrian, A.Shih (Naval Res. Lab., Washington, DC, USA).
Appl. Surf. Sci. (Netherlands), vol.16, no.1-2, p.125-38 (May-June 1983). (3rd Tri-Service Cathode Workshop, Fort Monmouth, NJ, USA, 23-26 March 1982).
The oxidation states of thin Ba films on Ir have been studied using an analysis of interatomic Auger lines. From published XPS data, some of the low energy AES were described in terms of various possible core, core, valence transitions where the core states were Ba states but the valence state could be either due to Ba or O. The magnitude of all AES lines, whose energy indicated an O valence state, was observed to increase with oxidation while those ascribed to Ba valence states decreased. The Ba 4d, 5p, valence transitions in the 65-75 V range appeared relatively free from clutter of other Ba and substrate lines and were the ones primarily used in determining the Ba-O bonding. The increase with oxidation of the interatomic Ba 4d, 5p, O 2p line at ~68V was found to be correlated with the increase in the O 2p loss peak. Furthermore, shifts in energy of this peak for various film thicknesses varied in accordance with corresponding shifts in O 2p binding energy with respect to the Fermi level. Also, the decrease with oxidation of the Ba 4d, 5p, 6s line at ~73 V was found to be correlated with the decrease in conduction electrons contributing to the surface plasmon peak. The manner in which these lines can be used to determine the extent of electron transfer in the formation of compounds other than BaO (such as BaC_2) is also given. (11 refs.)

109061 Interatomic Auger analysis of the oxidation of thin Ba films. II. Applications to impregnated cathodes. G.A.Haas, A.Shih, C.R.K.Marrian (Naval Res. Lab., Washington, DC, USA).
Appl. Surf. Sci. (Netherlands), vol.16, no.1-2, p.139-62 (May-June 1983). (3rd Tri-Service Cathode Workshop, Fort Monmouth, NJ, USA, 23-26 March 1982).
For pt.I see ibid., vol.16, p.125 (1983). The oxidation and thermal desorption of evaporated Ba films on different substrates have been characterized using low energy interatomic AES techniques. The films, which were deposited on W⟨100⟩ varied from a fractional layer to ~10 layers. Oxidation states, i.e. $Ba:O_x$, ranged from $x=0$ to $x\approx2$. Comparison of these data to those from actual impregnated cathodes allows one to infer the thickness and state of oxidation of the cathodes. The results indicate that the active state for 'B-type' impregnated cathodes can be reproduced by a near monolayer of the stoichiometric BaO on the W surface. The density of Ba atoms in this 'monolayer' should be ~one half that of the W atoms based on size consideration of the Ba compared to the W. This was confirmed by LEED. Measurements of the effusion of Ba compounds from the pores, the substrate interaction and the thermal evaporation indicate that on the W substrate, the monolayer BaO stoichiometric ratio is not only a stable configuration, but also is the one that has the lowest work function. The substrate work function is lowered because of the dipole formed from the adsorbed BaO. Studies of the electron interactions between the Ba and O indicate that a more complete electron transfer exists between the Ba and O for the BaO layer on the Ir substrate than on the W substrate. These results are based on the observation that O 2p states on the W substrate appear to be filled not only by Ba 6s but also by W valence electrons. (15 refs.)

109062 Auger characterization of new and aged dispenser cathode surfaces. G.Eng, H.K.A.Kan, K.T.Luey (The Aerospace Corp., Los Angeles, CA, USA).
Appl. Surf. Sci. (Netherlands), vol.16, no.1-2, p.181-8 (May-June 1983). (3rd Tri-Service Cathode Workshop, Fort Monmouth, NJ, USA, 23-26 March 1982).
The major changes in dispenser cathode surface signatures caused by aging were studied on B-type dispenser cathodes by operating them at high temperatures. By means of a computerized scanning Auger microprobe (SAM), the surface characterizations of three aged cathodes were measured and compared with those of a new cathode. Several hundred points were monitored on each sample to develop a good statistical description of each cathode surface, including both the impregnated core ends and the tungsten regions between the pores. A method of discrimination between impregnant regions has been developed, based on differences in the oxygen Auger peak shape and position. The results show that a surprisingly large fraction (>70%) of the new cathode surface could be similar to the impregnant. This fraction decreases to near 20% with age. The elemental composition of these different regions was examined by correlating the presence of each element to others. The elemental correlation showed that the dominant fraction of the cathode surface in early life is similar to a barium oxide on tungsten, and the cathode changes to an increasing fraction of surface tungsten oxide with aging. (14 refs.)

109063 Quantitative Auger-electron analysis of nonstoichiometric lead telluride. T.A.Smorodina, A.P.Tsuranov (A.F. Ioffe Physicotech. Inst., Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.11, p.1559-62 (Nov. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.11, p.1816-19 (Nov. 1982).
The authors have carried out a quantitative Auger-electron analysis of nonstoichiometric p-type lead telluride, which enables the degree of deviation of the material from stoichiometry to be determined. They have found a considerable enrichment of the surface with excess tellurium. The observed phenomenon of surface segregation is described by Guttman's equations (1975) for multi-component solid solutions. (3 refs.)

109064 Characterisation of computer differentiation of spectra in AES and its relation to differentiation by the modulation technique. M.P.Seah, M.T.Anthony, W.A.Dench (Div. of Materials Applications, NPL, Teddington, England).
J. Phys. E (GB), vol.16, no.9, p.848-57 (Sept. 1983).
Several computer methods of differentiating Auger electron spectra are analysed in terms of their relative signal-to-noise ratios, their distortion of the peak shape and their output intensity as a function of the differentiation amplitude, in order to maximise the measurement precision and detectability in surface analysis. These methods, a direct difference of two channels, the quadratic and cubic smoothing methods of Savitzky and Golay (1964), a variant of the latter and multiple smoothings are each compared in detail with the traditional analogue sinusoidal modulation method. The relative distortions of the techniques are established using the parameters of the Ag $M_{45}NN$ Auger electron doublet proposed by Seah and Anthony (1983). The overall comparisons show that the more complex methods are not necessarily of significantly greater benefit. (25 refs.)

109065 Low energy Auger spectrum of tungsten. I.Chorkendorff, J.Onsgaard (Fysisk Inst., Odense Univ., Odense, Denmark).
Phys. Scr. (Sweden), vol.T4, p.165-8 (1983). (Nordic Conference on Surface Science, Tampere, Finland, 18-20 Aug. 1982).
The low energy Auger spectra of tungsten ($N_{45}N_{67}X$ and $N_{23}N_{45}N_{67}$ where $X=N_{67}$, O_{23}) have been investigated both experimentally and theoretically. The spectra have been measured by using electron impact excitation under UHV conditions. Due to the strong lifetime broadening of the 4*p* and 4*d* levels the spectra are characterized by broad structures. The energy loss spectra have also been measured in order to approximate the background. Energies and intensities have been calculated in mixed coupling scheme applying *jj*-coupling in the initial state and intermediate coupling in the final state. The calculated and experimental results have been found in reasonable agreement. The observed line widths can be explained by lifetime broadening of the levels participating in the Auger process. (15 refs.)

109066 Tm studied by electron energy-loss spectroscopy and Auger electron spectroscopy. J.Onsgaard, I.Chorkendorff, O.Sorensen (Fysisk Inst., Odense Univ., Odense, Denmark).
Phys. Scr. (Sweden), vol.T4, p.169-72 (1983). (Nordic Conference on Surface Science, Tampere, Finland, 18-20 Aug. 1982).
The reflection electron energy-loss spectrum (ELS) of polycrystalline thulium has been studied with primary energies in the energy range (100-1000) eV. Surface and bulk excitations in the energy-loss region (0-200) eV have been identified. The line width of the giant resonance at 40 eV can be explained by a convolution of the initial and the final state density of states. A low energy transition is assigned as a valence band to conduction band excitation.

Oxygen adsorption shifts the plasmon energy significantly. The rough structure of the (100-180) eV Auger electron spectrum of Tm can be assigned as $N_{45}N_{67}N_{67}$, $N_{23}N_{45}N_{67}$ and $N_{45}N_{67}O_{23}$ transitions, and autoionization processes. (22 refs.)

109067 Surface preparation for quantitative Auger electron spectroscopy: mechanical polishing and inert gas ion sputtering. M.A.Burke, J.J.Schreurs (Westinghouse R&D Center, Pittsburgh, PA, USA).
Surf. & Interface Anal. (GB), vol.5, no.4, p.155-60 (Aug. 1983). (International Conference on Quantitative Surface Analysis, Teddington, England, 24-25 Nov. 1981).
Discusses the effect of surface preparation on surface composition as measured by Auger electron spectroscopy (AES). The problems of producing atomistically clean surfaces for calibration standards in quantitative AES analysis are illustrated by comparing the analyses of a series of copper-nickel binary alloys prepared by mechanical polishing and sputter cleaning with the compositions measured immediately after in situ fracture. Mechanical polishing results in surface enrichment by nickel for alloys of less than about 0.6 atomic fraction nickel, while alloys of greater than about 0.7 atomic fraction nickel exhibit surface enrichment by copper after mechanical polishing. Sputter cleaning results in a surface enrichment by nickel for all the alloy compositions considered ($X_{cu}<0.5$). Additionally, sputtering of the mechanically polished surfaces produces maxima in the surface nickel concentration, after short time sputtering, which coincide with the removal of the oxygen signals from the spectra. The results are discussed using a preferential sputtering model. (20 refs.)

109068 Auger spectra of lithium metal and 'oxidised lithium'. I.F.Ferguson, D.R.Masters, M.Turek.
Report ND-R-463(S), UKAEA, Risley, Lancs., England (May 1983), 26 pp.
Available from HMSO, London, England.
As part of a programme aimed at locating lithium in irradiated boron carbide, the Auger spectra of lithium metal and 'oxidised lithium' have been determined using a JAMP-3 Auger microprobe. It was found that the KVV Auger spectrum of elemental lithium was essentially identical in structure with the KVV Auger spectra of elemental Be, B and C, and with the LVV Auger spectra of Na, Mg, Al and Si. No adequate explanation could be offered for the occurrence of a lithium Auger signal at 46 eV, adjacent to the principal KVV lithium Auger transition at 51 eV. (27 refs.)

79.20H Electron impact: secondary emission

109069 Secondary emission properties of impregnated tungsten cathodes. R.E.Thomas (Naval Res. Lab., Washington, DC, USA), C.D.Morrill.
Appl. Surf. Sci. (Netherlands), vol.16, no.1-2, p.292-311 (May-June 1983). (3rd Tri-Service Cathode Workshop, Fort Monmouth, NJ, USA, 23-26 March 1982).
The secondary emission properties of impregnated tungsten cathodes have been studied using high resolution Auger spectroscopy to correlate the local variations in secondary emission (δ) with composition of the surface. It is found that for a tungsten surface activated with approximately a monolayer of Ba and oxygen (such as is found over most of the surface of a normally activated dispenser cathode) $\delta_{max}\sim2.2$ with a first crossover energy ~70 eV. Any improvement in δ on practical dispenser cathodes is due to either the high value of δ from impregnant in the exposed pores, or due to excess impregnant left on the surface by the surface preparation methods. The value of δ_{max} from excess impregnants is ~5.3 consistent with previous measurements on thick BaO films. From cathode to cathode the fraction of the surface area covered with excess impregnant varied considerably. Thus, the average δ from the cathodes was not very reproducible. Little or no difference in δ could be attributed to changes in impregnant composition. It was found that charging effects can limit the value of δ that can be obtained from the pore area exposed on the surface, unless the pore size is limited. Various types of surface treatments were tried to determine their effect on δ and the highest average δ over the cathode surface was obtained from surfaces that were gritblasted with Al_2O_3 as a final treatment after impregnation. (9 refs.)

79.20K Other electron impact phenomena

109070 Energy loss spectroscopy of oxygen chemisorption on tin. C.M.Stander (Nat. Phys. Res. Lab., CSIR, Pretoria, S Africa).
Appl. Surf. Sci. (Netherlands), vol.16, no.3-4, p.463-8 (July-Aug. 1983).
Electron energy loss spectroscopy (EELS) has been used to study the room temperature chemisorption of oxygen on tin. EELS are presented that show a continuous shift in surface plasmon energy loss from 10 to 6.5 eV during oxidation. The energy loss peak at 6.5 eV is attributed to the formation of SnO_2 while the higher losses are associated with the formation of non-stoichiometric SnO_2 containing Sn interstitials during the initial stages of oxidation. (16 refs.)

109071 Electron energy loss spectra and X-ray photoelectron spectra of $Ca_2V_2O_7$. I.M.Curelaru (Dept. of Materials Sci. & Engng., Univ. of Utah, Salt Lake City, UT, USA), E.Suonien, E.Minni, K.-G.Strid, T.Ronnhult.
J. Lumin. (Netherlands), vol.28, no.2, p.123-33 (May-July 1983).
The authors measured the electron energy loss spectra of $Ca_2V_2O_7$ in the reflexion mode at incident energies between 200 and 2400 eV, and the X-ray photoelectron spectra excited by Al Kα radiation. The abundant loss structure observed can be correlated with the possible interband transitions, collective oscillations, and excitation of O2s and V3p electrons within the $V_2O_7^{4-}$ ion. The gap width and molecular orbital (MO) spread (or splitting) is about 1 eV larger in the $V_2O_7^{4-}$ ion than in its component VO_4^{3-} ion. Excitation of O2s states, which may occur together with some MO over-gap transitions, displaces the collective oscillations about 7 eV towards lower energies. Deeper V3p electrons are excited with a maximum energy loss some 7 eV above their binding energy. Cross transitions from Ca3p levels into some empty states of the $V_2O_7^{4-}$ ion, or direct transitions to available states of the Ca^{2+} ion could not be unambiguously identified. The energy dependence of the excitation cross section and of the electron penetration depth results in a significant variation of the relative intensity of various losses over the investigated energy range. (41 refs.)

109072 Absorbed energy distribution in heterogeneous semiconductor structures. A.F.Akkerman, A.L.Gibrekhterman, A.V.Dvurechenskii (Inst. for High Energy Phys., Acad. of Sci., Alma-Ata, Kazakh SSR).
Phys. Status Solidi a (Germany), vol.78, no.2, p.K131-5 (16 Aug. 1983).
Investigates the transmission of electrons with energy of 5 to 20 keV through germanium and silicon semiconductor structures. In calculations the program ETRIN of simulating low energy electron transmission through heterogeneous media by the Monte-Carlo method is used. (7 refs.)

109073 Determination of valence-electron concentration in $AgTe_3$ by electron energy loss spectroscopy. C.M.Stander (Nat. Inst. for Materials Res., CSIR, Pretoria, South Africa), K.-J.Range.
Solid State Commun. (USA), vol.47, no.10, p.843-4 (Sept. 1983).
Electron energy loss studies have shown that the valence-electrons in $AgTe_3$ give rise to an electron plasma oscillation with a frequency that can be related to the density of these electrons. The density of valence-electrons in $AgTe_3$ is similar to that in Te but larger than that in Ag. The EELS spectra of $AgTe_3$ and Te are similar with the exception of an interband transition at 5 eV which occurs in Te but not in $AgTe_3$. These similarities support the view that $AgTe_3$ is a silver-stabilized cubic Te. (11 refs.)

109074 Elementary surface excitations and electron energy loss spectroscopy. H.Ibach (Inst. fur Grenzflaschenforschung und Vakuumphys., Kernforschungsanlage Julich, Julich, Germany).
Ultramicroscopy (Netherlands), vol.11, no.2-3, p.179-85 (1983). (Surface Imaging and Analysis with High Spatial Resolution, Wickenburg Inn, AZ, USA, 12-15 Jan. 1983).
Energy loss spectroscopy of electrons reflected from solid surfaces has become a major source of information about a variety of elementary excitations of the surface. These excitations comprise plasmons of free carriers in metals and semiconductors, interband transitions, electronic excitations of adsorbed molecules and, with high resolution spectroscopy, vibrations of adsorbates and the substrate. Understanding of surface chemistry is greatly improved by the spectroscopy of adsorbate vibrations since decomposition reactions of adsorbed molecules on surfaces are easily analysed by the characteristic eigenmodes of the products. In many cases new and unexpected surface species have been identified. One of the advantages of electron energy loss spectroscopy as opposed to other techniques is that different scattering mechanisms may be employed which have different selection rules with respect to the symmetry elements of adsorbate complexes. Recently even surface phonon spectroscopy has become possible, and the dispersion of Rayleigh waves has been measured throughout the Brillouin zone. (20 refs.)

109075 Electron energy loss spectroscopy in glancing reflection from bulk crystals. O.L.Krivanek (Dept. of Phys., Arizona State Univ., Tempe, AZ, USA), Y.Tanishiro, K.Takayanagi, K.Yagi.
Ultramicroscopy (Netherlands), vol.11, no.2-3, p.215-21 (1983). (Surface Imaging and Analysis with High Spatial Resolution, Wickenburg Inn, AZ, USA, 12-15 Jan. 1983).
Electron energy loss spectral (EELS) from clean and oxidized Si surfaces have been collected in glancing reflection. The results confirm the importance of multiple surface plasmon excitation in glancing reflection EM, and indicate only a limited usefulness of glancing reflection EELS as a microanalytical technique. (25 refs.)

79.20N Atom, molecule, and ion impact

109076 Application of low damage SIMS/AES/XPS of the Ba-O-W system to cathode characterization. B.C.Lamartine, J.V.Czarnecki, T.W.Haas (Air Force Wright Aeronautical Lab., MLBM, Wright-Patterson AFB, OH, USA).
Appl. Surf. Sci. (Netherlands), vol.16, no.1-2, p.207-19 (May-June 1983). (3rd Tri-Service Cathode Workshop, Fort Monmouth, NJ, USA, 23-26 March 1982).
The activation of an impregnated dispenser cathode was characterized by SIMS, AES and XPS on the basis of analogous results from prepared thin film model standards of the Ba-O-W system. Proper SIMS characterization required low damage conditions (500 eV Ar^+, 5 nA/cm^2) and ultrahigh vacuum (beter than 2×10^{-10} Torr during analysis). Individual low damage SIMS yields from different model structures varied by several orders of magnitude; and consequently, the identification of the activated cathode structure from model compound yields was straightforward. While X-ray induced AES of cathodes requires curve synthesis to identify the activation transition with temperature, the low damage SIMS yields showed obvious but continuous transitions through the activation temperatures. (30 refs.)

109077 Sputtering of CoSi(100) and $CoSi_2$(100) single crystal surfaces. G.R.Castro, J.Kuppers (Inst. fur Phys. Chem., Univ. Munchen, Munchen, Germany), Y.Ivashchenko.
Appl. Surf. Sci. (Netherlands), vol.16, no.3-4, p.453-62 (July-Aug. 1983).
The composition of CoSi(100) and $CoSi_2$(100) surfaces is shown to change considerably upon sputtering with Ar^+ ions in the energy range 300-3000 eV. Generally, preferential sputtering of Si is observed, more pronounced approaching low ion energies. The density corrected sputter yield ratio, k_{Si}/k_{Co}, is found to be different at the compounds investigated, suggesting an influence of the chemical bonding of the atoms to be sputtered at the respective surfaces. The results fit very well into recent sputter data of low/high atomic mass compounds. (18 refs.)

109078 Absolute measurements of thermal reemission of incident helium ions. T.Nishijima.
Bull. Electrotech. Lab. (Japan), vol.47, no.6, p.455-68 (1983). In Japanese.
Single crystals of refractory metals (V, Nb, Mo and W) have been irradiated with 50, 100 and 200 keV He^+ with fluences of 2×10^{13} to 3×10^{17} $ions/cm^2$ at room temperature. Thermal release spectra and the absolute reemitted fraction of incident helium ions have been measured in the course of subsequent near linear (stepwise) annealing with a ramp rate of 50K/min from 323K to 2000K with a calibrated quadrupole mass spectrometer. Approximately 100% release of the incident helium is observed up to 2000K. The reemitted fraction of incident helium at a given temperature decreases with increasing fluences, which indicates increases in concentration of stable helium traps due to higher irradiation damage formation. In the case of irradiation with higher fluences than about 1×10^{17} $ions/cm^2$, the helium release abruptly rises to higher values (gas-burst phenomena). SEM observations indicate the surface erosion (blister formation) during the steep rise of helium release at 1×10^{17} $ions/cm^2$ irradiation. (17 refs.)

109079 Secondary ion emission from transition metals bombarded by hydrogen ions. M.A.Vasil'ev, A.A.Kosyachkov, I.N.Makeyeva, V.T.Cherepin (Inst. of Phys. of Metals, Acad. of Sci., Kiev, Ukrainian SSR).
Phys. Met. (GB). Translation of: Metallofizika, Kiev (USSR), vol.4, no.3, p.515-24 (1982). [received: Aug. 1983]
The results are presented of the first systematic study on the mechanisms of the secondary ion emission (SIE) from transition metals bombarded by 6 keV hydrogen ions with 10^{-4} $A.cm^{-2}$ current density. To obtain comparative data, the surface of the targets was bombarded by argon ions. It is shown that bombardment with hydrogen ions can be used in secondary ion mass spectroscopy (SIMS) for analytical purposes. A series of comparable experiments has been carried out to measure the basic characteristics of SIE. The sputtering yield has been related to the degree of ionization. The energy distribution of secondary ions has been obtained and the mass distribution of secondary ions from the metals of the first long period has been studied. The kinetics has been investigated of the variation of the SIE characteristics with reactive gas pressure. The observed relationships are attributed to a mechanism which takes into account both the nature of the material and the enhancing effect of the change in the physical properties and chemical constitution of the surface saturated with hydrogen. (11 refs.)

109080 Ionization of an atom leaving a metal surface. V.Z.Khrinovskii (Inst. of Phys. of Metals, Acad. of Sci., Kiev, Ukrainian SSR).
Phys. Met. (GB). Translation of: Metallofizika, Kiev (USSR), vol.4, no.3, p.606-9 (1982). [received: Aug. 1983]
In recent years much interest has been shown in research on surfaces of solids. One of the most widely used methods is that of secondary ion-ion emission (SIIE) which is very sensitive to the structure of the surface state. A great number of models have been proposed for the SIIE mechanism; however, they fail to describe adequately the procedures determining the charge state of secondary ions. Using the electron-exchange mechanism previously developed, the author introduces a model hamiltonian to describe the metal-outgoing atom system. (6 refs.)

109081 Effect of primary ion energy on secondary ion emission from polycrystalline surfaces. P.Chakraborty, S.D.Dey (Saha Inst. of Nuclear Phys., Calcutta, India).
Indian J. Phys. Part B, vol.57B, no.2, p.125-32 (April 1983). [received: Sept. 1983]
The intensity of secondary Al^+, Ta^+ and Zr^+ ions from polycrystalline aluminium, tantalum and zirconium surfaces respectively as a function of bombarding Zn^+ and Cd^+ ion energies in the region of 3-10 keV has been investigated. In the case of zirconium, ion emission increases steadily with bombarding ion energy, followed by an almost saturation. For Al and Ta surfaces, ion emission increases almost linearly with bombarding ion energy and then attains a broad maximum, followed by a subsequent steady decline. As far as the decreasing behaviour of secondary ion emission is concerned, rate of fall is greater in the case of Ta (BCC crystal) than that of Al (FCC crystal). Results on cluster ion emission from aluminium under Cd^+ ion bombardment are also discussed. (9 refs.)

109082 Dependence of multiple-scattering distributions on the charge states of fast ions exiting from solid targets. E.P.Kanter (Phys. Div., Argonne Nat. Lab., Argonne, IL, USA).
Phys. Rev. A (USA), vol.28, no.3, p.1401-4 (Sept. 1983).
Measurements are reported on the multiple-scattering widths for 1-4-MeV N^+ projectiles in thin carbon targets as a function of the charge state of the outgoing ion. Evidence is found for a significant enhancement of the angular widths for *K*-vacancy-bearing emergent ions. A quantitative model is proposed demonstrating how the 'memory' of *K*-vacancy-producing collisions can give rise to such an enhancement despite apparent charge-state equilibration. (20 refs.)

109083 Molecular and chemical effects in Auger processes induced by molecular ions. Y.Yamazaki, A.Yasaka, N.Oda (Res. Lab. for Nuclear Reactors, Tokyo Inst. of Technol., Tokyo, Japan).
Phys. Rev. A (USA), vol.28, no.3, p.1873-5 (Sept. 1983).
The $AlL_{2,3}VV$ Auger electrons ejected under H^+ and $H_2{}^+$ ion bombardments were measured at the backward directions. The observed ratio of the Auger-electron yield per proton for $H_2{}^+$ to that for H^+ ejected from oxidized aluminum foils increases from 1.0 ± 0.1 to 1.6 ± 0.1 with an increase of the projectile energy from 0.25 to 1.2 MeV/amu, whereas the ratio for oxide-free aluminum foils remains approximately constant (1.1 ± 0.1). First-order perturbation theory fails to reproduce the observed results for both targets. (13 refs.)

109084 The diffraction of molecular hydrogen from copper surfaces. J.Lapujoulade, J.Perreau (Service de Phys. des Atomes et des Surfaces, CENS, Gif-sur-Yvette, France).
Phys. Scr. (Sweden), vol.T4, p.138-40 (1983). (Nordic Conference on Surface Science, Tampere, Finland, 18-20 Aug. 1982).
The diffraction of a molecular hydrogen nozzle beam (incident energy 77 meV) by various copper surfaces: Cu(100), Cu(110), Cu(115) has been experimentally studied. In every case a sharp diffraction pattern is obtained. For Cu(110) and Cu(115) the selective adsorption has been observed from which the bound state levels of the H_2-Cu potential are measured. A 9-3 potential well fits this result with a well depth $D=22.0\pm0.5$ meV and a range parameter $\sigma=2.8\pm0.1$ Å. From the diffraction pattern the corrugation of the potential is estimated. This corrugation is about five times greater than in the case of He-Cu. The reason of this high corrugation is not presently well understood. The authors did not find any evidence for dissociative chemisorption of hydrogen on copper even at the highest incident energy. (7 refs.)

109085 On the relative strength of He and H_2 diffraction from Ag(111). A.Liebsch, J.Harris (Inst. fur Festkorperforschung, KFA Julich, Julich, Germany).
Surf. Sci. (Netherlands), vol.130, no.2, p.L349-57 (Aug. 1983).
Under equivalent incident conditions, H_2 diffraction beams on Ag (111) have recently been observed tobe about one order of magnitude stronger than He beams. The authors show that this effect can be attributed to details of the interaction, in particular, the exponential increase of the corrugation amplitude towards the surface. By extending a previously developed theory for the interaction between He and a metal surface, they show that the H_2-Ag (111) repulsion is roughly 1.5 times larger than for He. However, the Van der Waals attraction is about three times stronger for H_2, so that the classical turning points of low-energy H_2 particles lie closer to the surface. Because of the stronger corrugation at short distances, H_2 diffraction intensities can be up to an order of magnitude larger than for He. (17 refs.)

109086 Inelastic scattering of He atoms from a Cu(110) surface. B.F.Mason, K.McGreer, B.R.Williams (Nat. Res. Council Canada, Ottawa, Canada).
Surf. Sci. (Netherlands), vol.130, no.2, p.282-94 (Aug. 1983).
A He beam has been used to measure inelastic scattering from a Cu(110) surface. The scattering was a result of predominantly single phonon events and both energy gain and loss processes were observed. This was in contrast to Cu(001) where only energy loss was observed. For Cu(110), aligned in the [001] azimuth, partial dispersion relations have been measured which meant that phonons with ΔQ values up to the zone boundary value have not been detected under the present experimental conditions. The elastic incoherent component varied with azimuthal angle for Cu(110). (19 refs.)

109087 Inelastic atom scattering from layers of atoms and molecules on Cu(110). B.F.Mason, B.R.Williams (Nat. Res. Council, Ottawa, Canada).
Surf. Sci. (Netherlands), vol.130, no.2, p.295-312 (Aug. 1983).
The vibrational properties of adsorbed layers have been studied using inelastic He atom scattering. The substrate was Cu(110) viewed along the [001] and [$\bar{1}$10] azimuth. The adsorbates included, Kr, Xe, CH_4, CD_4, C_2H_6, CO, CO_2 and O_2 and covered the region of both physisorption and chemisorption. Despite a range of binding energies and mass ratios the vibrational frequencies showed no dependence on the momentum change, i.e. scattering was dispersionless, although intensity changes occurred in the inelastic peaks. There seemed to be no dependence of the adsorbate spectra on coverage below a monolayer. The peaks of CH_4 and C_2H_6 appeared broader than those of Kr and Xe suggesting molecular motions. Further, CH_4 and C_2H_6 gave very similar spectra. Both energy gain and loss events were observed in the inelastic spectrum. For those adsorbates which gave multilayer adsorption (Xe, C_2H_6) changes in the spectra were observed as the second layer developed. In the latter category also, mixed layers (Xe on C_2H_6, Xe on CO and C_2H_6 on Xe) were studied. (16 refs.)

109088 Direct-inelastic and trapping-desorption scattering of N_2 and CH_4 from Pt(111). K.C.Janda (Noyes Lab. of Chemical Phys., California Inst. of Technol., Pasadena, CA, USA), J.E.Hurst, J.Cowin, L.Wharton, D.J.Auerbach.
Surf. Sci. (Netherlands), vol.130, no.2, p.395-409 (Aug. 1983).
Angle and velocity distributions for supersonic chopped beams of N_2 and CH_4 scattered from clean close-packed Pt (111) surfaces are reported. For specular direct-inelastic scattering N_2 and CH_4 velocity distributions can be characterised by empirical relationships used for Ar scattering. For instance, for specular scattering the following relation is found for Ar, N_2 and CH_4: $\langle KE_f\rangle = A(KE_i)+B(2kT_s)$, where $\langle KE_f\rangle$ is the average final kinetic energy, KE_i is the incident kinetic energy and T_s is the surface temperature. The beam and surface temperature independent coefficients *A* and *B* are, respectively: Ar 0.87, 0.17; N_2 0.79, 0.19 and CH_4 0.84, 0.25. Unlike Ar, N_2 desorbs from Pt with a Maxwell-Boltzmann velocity distribution near the surface temperature. Qualitatively the trapping probabilities for these molecules on Pt (111) are ordered: $Xe>N_2>CH_4>Ar$. (12 refs.)

79.20R Atomic and molecular beam interactions

109089 Atomic beam scattering from single crystal surfaces. D.R.Frankl (Dept. of Phys., Pennsylvania State Univ., University Park, PA, USA).
Prog. Surf. Sci. (GB), vol.13, no.4, p.285-356 (1983).
Application of atom-scattering to a variety of surface problems is expanding rapidly, owing in large part to the extreme surface-sensitivity of this probe. Helium is particularly useful because of its low mass and chemical inertness. Beams with velocity spreads of less than one percent and wavelength of the order of one Angstrom can be formed by nozzle expansion. The scattered flux from a clean, well-ordered crystal surface contains elastic and inelastic, coherent and incoherent, components. The coherent elastic component (i.e. the specular and diffracted beams) contains information about the crystallographic structure of the outermost atomic layer of the crystal and about the interaction potential between the crystal and the scattered particle. The latter manifests itself in the form of resonances between the incoming free-particle state, and the two-dimensional Bloch states bound in the potential well at the surface. Elastic scattering theory has reached the point where the resonance signatures in the various diffracted beams can be predicted accurately. Crystallographic information resides in the diffracted beam intensities. Theoretical interpretation is less well advanced, though some progress has been made with 'hard-wall' models. Experimental studies of reconstructed surfaces and chemisorbed overlayers appear very promising. In inelastic scattering, energy resolution has been achieved by both time-of-flight and diffraction methods. High-resolution studies on alkali halide surfaces have led to experimental determination of Rayleigh-wave dispersion relations over the full Brillouin zone. Preliminary results have also been obtained on some metals. (245 refs.)

79.60 PHOTOEMISSION AND PHOTOELECTRON SPECTRA

109090 Angle resolved photoelectron spectroscopy study of M-type cathode activation. K.D.Rachocki, B.C.Lamartine, T.W.Haas (Materials Lab., Air Force Wright Aeronautical Lab., Wright-Patterson Air Force Base, OH, USA).
Appl. Surf. Sci. (Netherlands), vol.16, no.1-2, p.40-54 (May-June 1983). (3rd Tri-Service Cathode Workshop, Fort Monmouth, NJ, USA, 23-26 March 1982).
Angle resolved photoelectron spectroscopy has been employed to investigate the chemistry occurring on osmium-ruthenium coated impregnated dispenser cathodes. This analytical technique allows the selection of acceptance angle of electrons analyzed in an X-ray photoelectron spectrometer, thus providing surface or depth enhancement of the signal. Spectra of the barium MNN Auger peaks and 3d and 4d photoelectron peaks were followed throughout activation. Surface enhancement, particularly of the barium MNN peak, showed a marked increase in the metallic component, confirming the increased concentration of metallic-like barium in the topmost layer. Auger-photoelectron energy separations were also plotted for comparison to previous data on impregnated dispenser cathodes and barium model compounds. By using higher resolution conditions, the authors have resolved the barium metal feature in the $M_4N_{4,5}N_{4,5}$ Auger transition at cathode operating temperatures. Using a digital subtraction technique, they are able to clearly distinguish elements which are predominant in the near-surface region as opposed to those which lie deeper in the cathode. (8 refs.)

109091 XPS studies on xanthate adsorption on galena surfaces. K.C.Pillai, V.Y.Young, J.O'M.Bockris (Dept. of Chem., Texas A&M Univ., College Station, TX, USA).
Appl. Surf. Sci. (Netherlands), vol.16, no.3-4, p.322-44 (July-Aug. 1983).
XPS measurement of the effect of xanthate adsorption of galena samples treated with de-oxygenated and oxygenated xanthate solutions have been made. Spectra of the Pb 4f, S 2P, C 1s and O 1s levels were recorded. Reference spectra of potassium ethyl xanthate and untreated galena samples were also obtained; these spectra were compared with previous results reported in the literature. In oxygenated solutions, the surface selvedge O 1s peak of galena has been altered by xanthate. Binding energies are such that there is evidence for a new surface compound on the galena surface. This is discussed in terms of interactions between the adsorbed intermediates of the O_2 reduction reaction and of the xanthate oxidation process. Implications for in situ flotation are discussed. (55 refs.)

109092 Dependence of surface composition of Zr-Ni intermetallic compounds on bulk composition and treatment. V.I.Nefedov, V.V.Lunin, N.G.Chulkov (Inst. of General & Inorganic Chem., Acad. of Sci., Moscow, USSR).
Phys. Met. (GB). Translation of: Metallofizika, Kiev (USSR), vol.4, no.3, p.503-14 (1982). [received: Aug. 1983]
Deals with an X-ray photoelectron study of the dependence of the surface composition of the intermetallic compounds Zr_2Ni, ArNi and $ZrNi_5$ on the holding time in air at 200°C. An investigation was conducted of the changes in the relative intensities of the lines Zr3d, Ni3p and Ni2p during ionic sputtering and for different photoelectron angles of escape. After oxidation the surface layer of the intermetallic compounds has the following structure: the uppermost layer is enriched with Ni (NiO), its content increasing with holding time, and next is a layer enriched with ZrO_2. Minimum Ni/Zr is observed 10 to 40 Å from the surface, depending on the composition and treatment time of the intermetallic compound. Next is a layer enriched with Ni, and, at a depth of 1000-1600 Å, the stoichiometric composition is reached. The formation of a Ni film on the surface of ZrO_2 is due to the diffusion of Ni through the film of oxides. (10 refs.)

109093 Modification of bulk band photoemission features by Ge overlayers. P.Zurcher (Xerox Res. Center, Palo Alto, CA, USA), J.Anderson, D.Frankel, G.J.Lapeyre.
J. Vac. Sci. & Technol. B (USA), vol.1, no.3, p.682-3 (July-Sept. 1983). (10th Annual Conference on the Physics and Chemistry of Semiconductor Interfaces, Santa Fe, NM, USA, 25-27 Jan. 1983).
Summary form only given. Electronic structure effects due to overlayers of Ge on GaAs (110) were studied with polarization-dependent angle resolved photoemission spectroscopy (PARPES) utilizing synchrotron radiation. Ge was deposited (about 1/2 monolayer) on cleaved *p*-type crystals at room temperature and annealed to obtain a (1×1) LEED pattern and PARPES anisotropy. In the normal emission spectra the clean-surface interband emission peaks were observed to change their binding energy after the addition of Ge. The magnitude of the adsorption induced shifts is different for different interband transitions. (3 refs.)

109094 Angle-resolved photoemission study of GaAs(100) surfaces grown by molecular beam epitaxy. L.G.Salmon, T.N.Rhodin (School of Appl. & Engng. Phys., Cornell Univ., Ithaca, NY, USA).
J. Vac. Sci. & Technol. B (USA), vol.1, no.3, p.736-40 (July-Sept. 1983). (10th Annual Conference on the Physics and Chemistry of Semiconductor Interfaces, Santa Fe, NM, USA, 25-27 Jan. 1983).
Angle-resolved ultraviolet photoemission spectroscopy (ARUPS) using synchrotron radiation has been used to advance understanding of the surface electronic structure of reconstructed GaAs(100) surfaces. ARUPS spectra were taken using a variable energy polarized photon source ($\hbar\omega$=15-100 eV). GaAs(100) surfaces with (1×2), *c*(8×2), and (4×6) reconstructed structures were grown in situ by molecular beam epitaxy (MBE) and characterized by in situ Auger electron spectroscopy (AES) and low energy electron diffraction (LEED). Surface state peak positions were measured across the surface Brillouin zone and the peak positions and dispersion characteristics were determined. The results were consistent with occurrence of the backbonded surface states for ideal GaAs(100) surfaces described by Pollman and Pantelides (1978). Some surface state structures not predicted by them were also observed. The (1×2) As-stabilized surface showed surface states with bonding energies of −6.0 and −9.0 eV corresponding to the two backbonded surface states predicted theoretically for the ideal As-terminated GaAs(100) surface. Three other surface state bands were observed at −1.0, −3.0, and −12.0 eV which were not predicted. All five surface states continued to be observed on the *c*(8×2) and (4×6) Ga-rich surfaces. Two additional surface states were also observed at binding energies of −10.0 and −14.0 eV for the Ga-rich (4×6) surface. The surface state at −9.0 eV was not observed for the less Ga-rich *c*(8×2) surface and neither deep surface state was present for the (1×2) As-rich surface. In addition, 1-9 monolayer Ge single-crystal epitaxial overlayers were grown on the three clean reconstructed GaAs surfaces. Photoelectron emission from the GaAs-derived surfaces states was strongly attenuated. The surface reconstruction of the GaAs was removed by Ge overlayers three monolayers or greater in thickness after which the Ge overlayer subsequently developed into a stable (1×2) two-domain structure. The number of Ge overlayers required to overcome the reconstruction features and to initiate stable overlayer growth depended on the nature of the initial GaAs surface reconstruction. (23 refs.)

109095 Recent developments in the field of bremsstrahlung isochromatic spectroscopy. H.Scheidt (Phys. Inst., Univ. Wurzburg, Wurzburg, Germany).
Fortschr. Phys. (Germany), vol.31, no.7, p.357-401 (1983). In German.
Starts with a comparison of the characteristics of 5 methods for the wide band spectroscopy of vacant positions: photoelectron, secondary electron, quanta absorption and reflection, appearance potential, and Bremsstrahlung-isochromatic spectroscopy (BIS). Despite the advantages of BIS, which are listed, it has never been as widely used as photoemission techniques. This is because of the bulkiness of the X-ray monochromator equipment and the low overall sensitivity. Hence its application is limited to systems which are thermally very stable, and it is virtually excluded from surface physics. Traditional BIS, in the soft X-ray region, is reviewed next, followed by a variant which enables the crystal monochromator to be dispensed with. BIS in the UV quantum energy range is then described, together with new developments in the low energy region which make it possible to use BIS in surface physics. (109 refs.) *D.J.B.*

109096 Hydrogen diffusion and hydride formation at the metal-hydride interface. R.A.Butera (Dept. of Chem., Univ. of Pittsburgh, Pittsburgh, PA, USA), J.H.Weaver, D.J.Peterman, A.Franciosi, D.T.Peterson.
J. Chem. Phys. (USA), vol.79, no.5, p.2395-9 (1 Sept. 1983).
Synchrotron radiation photoemission has been used to examine interface reaction of overlayers of V and Ca deposited onto clean surfaces of the bulk hydride YH_2 and the deuteride $NbD_{0.75}$. Changes in the hydrogen-induced bonding bands and the d bands near E_F and variations in the intensities of

the substrate core level emission as a function of metal coverage indicate that hydrogen diffuses from the substrate into the overlayer. The results are discussed in terms of the mechanism for hydride formation. (17 refs.)

109097 Semiconductor electrodes. LII. Photoelectron spectroscopic determination of the structure of thin platinum silicide layers formed on Si (100) and Si (111) for use as electrodes. G.A.Hope, F.-R.F.Fan, A.J.Bard (Dept. of Chem., Univ. of Texas, Austin, TX, USA).

J. Electrochem. Soc. (USA), vol.130, no.7, p.1488-91 (July 1983).

Platinum silicide was grown on (100) and (111) silicon by vacuum annealing an evaporated layer (0-15 nm thick) at 400°C, immediately following deposition. The element distribution in the product layer was measured using electron spectroscopy (XPS and AES) in conjunction with argon ion sputtering of the sample. The silicide thus produced was covered by a thin surface layer of SiO_2. The decrease in platinum concentration with increasing penetration into the sample was characteristic of a reaction mechanism in which a platinum species diffuses into the Si. (10 refs.)

109098 A theory of resonant photoemission in Ni. T.Jo (Dept. of Maths., Imperial Coll., London, England), A.Kotani, J.-C.Parlebas, J.Kanamori.

J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2581-91 (July 1983).

A theory is presented for the resonant 3*d*-band photoemission spectra in Ni on the basis of a hybridized *s* and *d*-band model. The interference effect is taken into account between the 3*p*-core electron excitation followed by a super Coster-Kronig decay and the direct 3*d*-electron excitation. The photoemission intensities and their spin polarizations both for the 6 eV satellite and Auger peaks are calculated as a function of the incident photon energy ν, and the results are in good agreement with experiments. It is shown that the interference effect is important in explaining the observed ν-dependence of the spin polarization of satellite. (20 refs.)

109099 X-ray photoelectron spectroscopy study of the ionic configuration of the spinel $CuMnCoO_4$. V.A.M.Brabers, F.van Setten (Dept. of Phys., Eindhoven Univ. of Technol, Eindhoven, Netherlands).

J. Phys. D (GB), vol.16, no.9, p.L169-72 (14 Sept. 1983).

X-ray photoelectron spectra are reported for the spinels $CuMnCoO_4$, $CoMn_2O_4$, Co_2MnO_4 and $CoZnMnO_4$, from which the following ionic configurations can be induced: ${Cu_{0.65}}^{+}{Mn_{0.35}}^{3+}[{Cu_{0.35}}^{2+}Co^{3+}Mn_{0.65}]O_4$, $Co^{2+}[{Mn_2}^{3+}]O_4$, $Co^{2+}[Co^{3+}Mn^{3+}]O_4$ and $Zn[Co^{3+}Mn^{3+}]O_4$. (7 refs.)

109100 X-ray photoelectron spectroscopy study of the cation valencies in nickel manganite. V.A.M.Brabers, F.M.Van Setten, P.S.A.Knapen (Dept. of Phys., Eindhoven Univ. of Technol., Eindhoven, Netherlands).

J. Solid State Chem. (USA), vol.49, no.1, p.93-8 (Aug. 1983).

The X-ray photoelectron spectra of $NiMn_2O_4$, $NiMnZnO_4$, Mn_2TiO_4, $MnFe_2O_4$, and Mn_3O_4 are reported. The shift and broadening of the Mn-2*p*, Mn-3*s*, and Mn-3*p* lines in $NiMn_2O_4$, compared with those of the other compounds, are indicative of the charge distribution ${Ni_{1-\nu}}^{2+}{Mn_\nu}^{2+}[{Ni_\nu}^{2+}{Mn_{2(1-\nu)}}^{3+}{Mn_\nu}^{4+}]O_4$ ($\nu \simeq 0.9$). The values of multiplet splitting of the Mn3*s* level also support this distribution. (16 refs.)

109101 Quantitative analysis of titanium nitride thin film by means of X-ray photoelectron spectroscopy. K.Yabe, M.Suzuki (Government Industrial Dev. Lab., Hokkaido, Sapporo, Japan), Y.Igasaki, T.Yamashina.

J. Vac. Soc. Jpn. (Japan), vol.26, no.6, p.556-62 (1983). In Japanese.

To establish quantitative analysis of titanium nitride thin film, several experiments were carried out using X-ray photoelectron spectroscopy (XPS). It was demonstrated that two kinds of relative sensitivity ratio of nitrogen to titanium could be determined using standard materials. The one is the relative sensitivity in the primary meaning and it was determined using secondary standard materials of chemical reagents. The other is the one adoptable for a quantitative analysis accompanying Ar^+ ion sputter etching such as depth profiling and it was obtained from measurements on the standard titanium nitride films which were prepared by thermal nitriding and reactive RF sputtering. Change in atomic composition of the surface by an Ar^+ ion bombardment was investigated. It was found that the ratio of the sputtering yield of nitrogen to that of titanium was constant for the samples having nitrogen composition above 0.5 (atm.%). It is confirmed that the accurate quantitative depth analysis is possible for a sampling having composition within that range. (9 refs.)

109102 Transition from adiabatic to sudden core-electron excitation: N_2 on Ni(100). J.Stohr, R.Jaeger (Corp. Res.-Sci. Labs., Exxon Res. & Engng. Co., Linden, NJ, USA), J.J.Rehr.

Phys. Rev. Lett. (USA), vol.51, no.9, p.821-4 (29 Aug. 1983).

The first systematic study of the energy dependence of a core-level shake-up feature is presented. In contrast to expectations the shake-up peak remains nearly unchanged in intensity down to ~15 eV above threshold. The early and abrupt turn-on of the multi-electron satellite found experimentally is well explained by a theory which describes the transition from adiabatic to sudden core-level excitation by a simple exchange-interaction picture. (17 refs.)

109103 Temperature dependence of the exchange splitting in Ni studied by spin-polarized photoemission. H.Hopster, R.Raue, G.Guntherodt (Phys. Inst., Univ. Koln, Koln, Germany), E.Kisker, R.Clauberg, M.Campagna.

Phys. Rev. Lett. (USA), vol.51, no.9, p.829-32 (29 Aug. 1983).

Angle- and spin-resolved photoemission spectra from Ni(110) have been measured in the temperature range $0.5 \leq T/T_c \leq 0.94$. The data cannot be reconciled either with the predictions of local band theory assuming a temperature-independent exchange splitting or with a pure Stoner model. It is concluded that the exchange splitting decreases with increasing temperature and that spin fluctuations strongly influence the photoemission line shapes. (17 refs.)

109104 Photoemission studies of $Pd_{80-x}Si_{20}Co_x$ amorphous alloys. K.Hricovini (Inst. of Phys., Electrotech. Faculty, Slovak Tech. Univ., Bratislava, Czechoslovakia), P.Mikusik, J.Krempasky.

Phys. Status Solidi b (Germany), vol.118, no.2, p.823-7 (1 Aug. 1983).

X-ray and UV photoemission measurements of the core levels and valence bands of $Pd_{80-x}Si_{20}Co_x$ amorphous alloys are reported. XPS spectra show a broadening of the cobalt 2p-levels in the alloys while the binding energies are the same as in the polycrystalline Co. The behaviour of Co atoms during the alloying process is discussed. UPS spectra of the valence bands show a shift of Pd 4d-band to higher binding energies and a cobalt contribution to the density of states above the Fermi level of Pd-Si alloy. (17 refs.)

109105 Angular resolved photoemission from Cu(110). A.Baalmann, H.Przybylski, M.Neumann, G.Borstel (Fachbereich Phys., Univ. Osnabruck, Osnabruck, Germany).

Phys. Scr. (Sweden), vol.T4, p.148-51 (1983). (Nordic Conference on Surface Science, Tampere, Finland, 18-20 Aug. 1982).

Angular resolved normal emission photoelectron spectra of Cu(110) using linearly polarized light ($\hbar\omega = 21.22$ eV) are presented. Within the frame of the three-step-model of photoemission corresponding spectra have been calculated and good agreement with experiment is achieved. Spin-orbit coupling is important and gives rise to a relaxation of single-group dipole selection rules even for low *Z* materials. Photoelectron spectra are critically dependent on external experimental parameters. All features in the experimental spectra may be interpreted by direct transitions. (16 refs.)

109106 Calculation of photoemission spectra using an energy dependent potential. C.G.Larsson, P.O.Nilsson (Dept. of Phys., Chalmers Univ. of Technol., Goteborg, Sweden).

Phys. Scr. (Sweden), vol.T4, p.155-7 (1983). (Nordic Conference on Surface Science, Tampere, Finland, 18-20 Aug. 1982).

The effect of exchange and correlation in an excited system is studied by means of photoemission calculations. This is realized via an energy dependent muffin tin potential calculated from the Hedin-Lundqvist dynamic potential (1971). Results are presented for the Cu(111) and (100) surfaces. (10 refs.)

109107 UPS studies of α-phase alloys CuX and AgX (X=Zn, Ga, Ge and As). M.Lahdeniemi, E.Ojala (Dept. of Phys. Sci., Univ. of Turku, Turku, Finland).

Phys. Scr. (Sweden), vol.T4, p.158-61 (1983). (Nordic Conference on Surface Science, Tampere, Finland, 18-20 Aug. 1982).

Photoelectron spectra of polycrystalline α-phase CuX and AgX (X=Zn, Ga, Ge, and As) have been measured using the photon energy of 21.2 eV. The alloy-host difference spectra are compared with theoretical calculations. The origin of the structures in difference spectra and the observed weak impurity dependence of the antiresonance structure are discussed. (19 refs.)

109108 On the role of spin-orbit coupling and crystal symmetry on the spin-polarization of photoelectrons in nonmagnetic crystals. M.Wohlecke, G.Borstel (Fachbereich Phys., Univ. of Osnabruck, Osnabruck, Germany).

Phys. Scr. (Sweden), vol.T4, p.162-4 (1983). (Nordic Conference on Surface Science, Tampere, Finland, 18-20 Aug. 1982).

The light-induced electron-spin polarization (ESP) for electrons emitted normally from (111)-faces of Cu, Ag and Au is calculated within a spin-dependent three-step-model. Both the energetic positions and the strengths of the spectral features in the ESP may be interpreted as a function of the increasing spin-orbit coupling on the basis of the corresponding bandstructure along Λ. The general applicability of group-theoretical selection rules to the ESP is demonstrated and general symmetry considerations for the occurrence of a nonzero ESP in crystals are given. (14 refs.)

109109 XPS investigation of Ni/Si(111) interfaces. T.T.A.Nguyen, R.Cinti (Groupe des Transitions de Phases, CNRS, Grenoble, France).

Phys. Scr. (Sweden), vol.T4, p.176-8 (1983). (Nordic Conference on Surface Science, Tampere, Finland, 18-20 Aug. 1982).

The early stages of the formation of thin layers (~15 monolayers) of Ni evaporated onto Si(111) clean surfaces and their transformation upon heat treatment have been investigated by XPS. For surface coverage θ sequentially increased from 6×10^{-2} to 1 equivalent monolayer, the $Ni2p_{3/2}$ peak moves from −853.9 eV, 0.9 eV lower than its bulk value, to −853.6 eV, the valence band spectra show a rapid prevalence of the derived Ni *d*-band, while the Si 2*p* remains constant in energy. Angular analysis of the core level spectra of the as-deposited and annealed layers shows composition inhomogeneity for annealing temperatures $T_a \lesssim 600$°C. At higher T_a a uniform $NiSi_2$ is formed. Experimental results are discussed in relation to existing measurements and calculations on the electronic structures of nickel silicides. (8 refs.)

109110 Semiconductor core-level to valence-band maximum binding-energy differences: precise determination by X-ray photoelectron spectroscopy. E.A.Kraut, R.W.Grant, J.R.Waldrop, S.P.Kowalczyk (Microelectronics Res. & Dev. Center, Rockwell Internat., Thousand Oaks, CA, USA).

Phys. Rev. B (USA), vol.28, no.4, p.1965-77 (15 Aug. 1983).

Angle-resolved core-level and valence-band X-ray photoelectron spectroscopy (XPS) data for GaAs(110), Ge(110), and Ge(111) surfaces are analyzed to determine core-level to valence-band maximum binding-energy differences to a precision of the order of the room-temperature thermal energy. A method for markedly improving the precision with which the position of the valence-band maximum in XPS data can be located is presented. This method is based on modeling the XPS valence-band spectrum in the vicinity of the valence-band maximum by an instrumentally broadened theoretical valence-band density of states and fitting this model to the experimental data by using the least-squares method. The factors which influence the attainable precision for determining core-level to valence-band maximum binding-energy differences are quantitatively discussed. These factors include the presence of occupied surface states, band bending, surface chemical shifts, background effects associated with inelastic processes, instrumental line shape, and spectrometer calibration accuracy. The spin-orbit-split components of the Ga, As, and Ge 3*d* core lines are resolved and binding energies of these components, measured relative to the valence-band maxima in GaAs and Ge, are reported. (55 refs.)

109111 Surface effects in Du intermetallics: a resonant photoemission study. W.D.Schneider, C.Laubschat, G.Kalkowski (Inst. fur Atom- und Festkorperphys., Freie Univ. Berlin, Berlin, Germany), J.Haase, A.Puschmann.

Phys. Rev. B (USA), vol.28, no.4, p.2017-22 (15 Aug. 1983).

The Eu-transition-metal compounds $EuAg_5$, $EuRh_2$, $EuPt_5$, and $EuPd_5$ were studied by resonant $4d \rightarrow 4f$ photoemission techniques. In divalent $EuAg_5$, a surface core-level shift of the final-state $4f^6$ multiplet components of 0.75 eV is found. For the trivalent Eu compounds $EuPt_5$ and $EuPd_5$ as well as for the mixed-valence compound $EuRh_2$, a surface valence change to the lower-valence state is observed. For $EuPt_5$, an inhomogeneously mixed-valence surface is noticed, pointing to a strong coordination dependence of the surface valence transition. The energy position of the final-state 4*f* screening orbital is discussed on the basis of 4*d* photoemission and photoabsorption threshold energies. (37 refs.)

109112 X-ray photoelectron spectroscopy study of the surface composition of CoO-MgO solid solutions. A.Cimino, B.A.De Angelis, G.Minelli (Centro di Studio SACSO, Univ. di Roma, Roma, Italy).

Surf. & Interface Anal. (GB), vol.5, no.4, p.150-4 (Aug. 1983). (International Conference on Quantitative Surface Analysis, Teddington, England, 24-25 Nov. 1981).

The surface composition of CoO-MgO solid solutions has been investigated by XPS. The samples (prepared at 1200°C in air) were checked to be homogeneous by X-ray diffraction analysis and by lattice parameter measurements. The study utilized peaks at different kinetic energies: Co 2p, O 1s, Co 3s, Mg 2s, Co 3p, Mg 2p and the Auger transition Mg KLL. It was shown that the specimens have a surface composition slightly different from the bulk, because of the formation of surface magnesium hydroxide. No segregation of cobalt was found. The results have a bearing on the catalytic activity of oxide solid solutions. (15 refs.)

109113 Surface quantitative analysis of Cr-O systems by XPS. C.Battistoni, G.Cossu, G.Mattogno, E.Paparazzo (Istituto di Teoria, Struttura Elettronica e Comportamento Spettrochimico dei Composti di Coordinazione, Roma, Italy).
Surf. & Interface Anal. (GB), vol.5, no.4, p.173-6 (Aug. 1983). (International Conference on Quantitative Surface Analysis, Teddington, England, 24-25 Nov. 1981).
A comparison among O/Cr atomic ratios obtained from XPS Cr $2p_{3/2}$ and O 1s spectra in pure inorganic compounds, employing the Elemental Sensitivity Factors approach and the so-called 'First-Principles Model' is reported. (23 refs.)

109114 Photo-electron emission microscopy of work function changes. H.Bethge, M.Klaua (Inst. fur Festkorperphys. und Elektronenmikroskopie, Akad. der Wissenschaften, Halle/Saale, Germany).
Ultramicroscopy (Netherlands), vol.11, no.2-3, p.207-13 (1983). (Surface Imaging and Analysis with High Spatial Resolution, Wickenburg Inn, AZ, USA, 12-15 Jan. 1983).
Photo-electron emission microscopy (PEEM) under ultra-high vacuum (UHV) conditions is one of the various surface imaging techniques least developed but nevertheless most promising. Excited by ultra-violet radiation, the low energy photo-electrons are only surface sensitive via the effect of the work function. Work function changes due to different materials, orientations, adsorption or reaction layers, and step densities can be visualized microscopically with a lateral resolution of some 10 nm. PEEM and Auger electron spectroscopy (AES) have been combined in a true UHV apparatus to complement surface imaging by the surface-sensitive element analysis. First investigations were focused on the orientation dependence of the photoemission in polycrystalline Ni and on contrast changes by work function changes due to the adsorption of oxygen on differently oriented Ni grains. By recrystallization large Ni(111) and Ni(110) grains were obtained, the orientations of which were determined by LEED. Relative measurements of the photoemission current by a spot photometer, and the Auger signals of O and Ni depending on oxygen exposure clearly show the different stages of chemisorption and oxidation. Measured differences due to different orientations and the sensitivity to low oxygen coverages are much higher for PEEM than for AES. Present instrumental limitations and future improvements are discussed. (14 refs.)

79.70 FIELD EMISSION AND FIELD IONIZATION

109115 Determination of barium and calcium evaporation rates from impregnated tungsten dispenser cathodes. G.L.Jones, J.T.Grant (Res. Inst., Univ. of Dayton, Dayton, OH, USA).
Appl. Surf. Sci. (Netherlands), vol.16, no.1-2, p.25-39 (May-June 1983). (3rd Tri-Service Cathode Workshop, Fort Monmouth, NJ, USA, 23-26 March 1982).
The evaporation rates of barium and calcium from impregnated tungsten dispenser cathodes have been determined by both a vapor-collect method and line-of-sight mass spectrometry. Cathodes having molar ratios of BaO, CaO, and Al_2O_3 of 4:1:1, 5:3:2, and 1:1:1 have been studied. All measurements were conducted in ultrahigh vacuum. For the vapor-collect method, a W(110) collector was found to be suitable for monolayer growth. The procedure involved plotting the ratio of the adsorbate Auger peak-to-peak height to that from the collector as a function of collection time. Break-points in these plots characterized the collection of one monolayer of adsorbate. A geometrical correction then allowed the evaporation rates to be determined. Evaporation rates were determined at cathode temperatures of 1050, 1100, and 1150°C. For the line-of-sight mass spectrometry an extranuclear quadrupole was used. The quadrupole was capable of measuring species up to 300 amu. Measurements with the quadrupole were made on a 5:3:2 and a 4:1:1 cathode. Results obtained using these two methods are compared. (13 refs.)

109116 Field evaporation of silicon and field desorption of hydrogen from silicon surfaces. G.L.Kellogg (Sandia Nat. Labs., Albuquerque, NM, USA).
Phys. Rev. B (USA), vol.28, no.4, p.1957-64 (15 Aug. 1983).
The field evaporation of silicon in ultrahigh vacuum and in hydrogen has been studied with the use of the pulsed-laser atom probe. Measurements of the ion yields of various field-evaporated and field-desorbed species were made as a function of applied voltage, laser power, hydrogen background pressure, and laser pulse rate. The results indicate that, in ultrahigh vacuum and above cryogenic temperatures, field evaporation of silicon is qualitatively the same as for metals. In hydrogen, however, the field-evaporation process is quite different from that of metals, with the rate-limiting step being the field-enhanced formation of surface hydrides. Field-desorbed H^+ and H_2^+ ions are shown to arise from a field-adsorbed binding state, and the voltage range where H_2^+ dissociates to H^+ is used to calibrate the electric field strength. The low-temperature evaporation field of silicon is estimated from this calibration to be 3.3-3.6 V/Å, which is considerably higher than the currently accepted value of 2.0 V/Å. Field-desorbed H_3^+ ions are detected only when oxide contamination is present on the silicon surface. If it is assumed that the mechanism of H_3^+ formation is the same as that proposed for metals, this observation suggests that weakly bound, chemisorbed hydrogen atoms exist on silicon only in the presence of surface contamination. (38 refs.)

109117 Field evaporation of silicon surfaces. T.Sakata (Dept. of Integrated Arts & Sci., Univ. of Osaka Prefecture, Osaka, Japan), J.H.Block.
Surf. Sci. (Netherlands), vol.130, no.2, p.313-25 (Aug. 1983).
Quantitative measurements on field evaporation of Si (111) surfaces in hydrogen imaging gas have been carried out by field ion microscopy. The field evaporation rate is found to increase exponentially with increase of the reciprocal of tip temperature in the range 80-103K. The evaporation field strength increases with increase of tip temperature in the investigated range, 80-300K. Within the applied pressure range, 5×10^{-6} to 2×10^{-4} Torr of hydrogen gas, the evaporation rate linearly increases with the gas pressure. Similar effects of temperature and gas pressure on field evaporation of Si(111) surfaces have been observed also in silane imaging gas. A model, based on a field-induced formation of surface hydrides as a rate-determining step, is proposed, which accounts for all the experimental results of the field evaporation process. (36 refs.)

79.75 EXOELECTRON EMISSION

109118 Intense exoelectron emission from fine particles of Al_2O_3 and its dependence on the conductivity of the substrate material. K.Kawabata (Radiation Center of Osaka Prefecture, Osaka, Japan).
Phys. Status Solidi a (Germany), vol.78, no.2, p.K127-30 (16 Aug. 1983).
The author found an intense 'thermally stimulated electron emission' (TSEE) in fine particles of Al_2O_3 irradiated with γ-rays, and the yield depends strongly on the conductivity of the substrate, becoming maximum when the substrate is a metal. (3 refs.)

80.00 CROSS-DISCIPLINARY PHYSICS AND RELATED AREAS OF SCIENCE AND TECHNOLOGY

81.00 MATERIALS SCIENCE

109119 ASTM D 4000: a new classification system devoted to plastics. F.O.Swanson (Engine Engng. Div., Ford Motor Co., Dearborn, MI, USA).
Plast. Eng. (USA), vol.39, no.1, p.31-3 (Jan. 1983).
By using this recently published classification standard as a guide, one can benefit in three important ways: confusion can be reduced when specifying plastics; costs can be controlled; and one's basic understanding of plastics can be increased. (no refs.)

81.10 METHODS OF CRYSTAL GROWTH AND PURIFICATION

(for physics of crystal growth, see 61.50C; for epitaxial growth methods, see 81.15)

109120 Purification of mercuric iodide. V.M.Zaletin, I.N.Nozhkina (Lenin Komsomol Novosibirsk State Univ., Novosibirsk, USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1087-90 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1288-91 (Aug. 1982).
The purification of HgI_2 was performed by three methods: recrystallisation from HCl, chemical-thermal, and repeated vacuum sublimation. The results obtained on the purification of HgI_2 by all three methods are comparable with the most effective method used abroad. The best results were achieved using repeated vacuum sublimation with preliminary melting of the original HgI_2 material. The content of impurities in mercuric iodide by this method is less than $1\times10^{-4}\%$ by weight. (7 refs.)

109121 Purification of zirconium by electrotransport. R.H.Zee, J.F.Watters.
Report AECL-8051, Atomic Energy Canada Ltd., Chalk River, Ont. (April 1983), 10 pp.
An electrotransport apparatus for purifying reactive metals is described. A large d.c. current ($\sim 10\ \mathrm{A/mm^2}$) is applied to the specimen inside an ultra high vacuum chamber. This chamber is evacuated using an ion pump and a titanium sublimation pump. It is bakeable to 650K and is capable of maintaining a vacuum of 7×10^{-8} Pa. Resistivity ratio results from several preliminary runs in zirconium indicate a reduction in overall impurity level by 60% after a typical run at 1750K for ~120h. (293 refs.)

81.10B Growth from vapour

109122 Growth conditions of $CuBTe_2$ (B=Ga, In) single crystals by the closed tube chemical vapour transport technique. F.Leccabue, C.Pelosi (Maspec-CNR Inst., Parma, Italy).
Mater. Lett. (Netherlands), vol.2, no.1, p.42-4 (July 1983).
Ternary chalcopyrite $CuInTe_2$ and $CuGaTe_2$ single crystals were grown by the closed tube chemical vapour transport technique for the first time. The growth conditions were selected so that the starting compounds were not dissociated by the peritectoid reaction. All samples were electrically characterised by means of the van der Pauw technique and were found to have a p-type conductivity in all cases. (12 refs.)

109123 Growing mixed crystals of $CdS_{1-x}Se_x$ from the vapor phase. B.A.Kazennov, V.F.Chernysheva (State Univ., Leningrad, USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.2, p.242-3 (March-April 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.2, p.409-11 (March-April 1983). [received: Sept. 1983]
The properties of CdS and CdSe crystals and their solid solutions depend on the purity of the starting material and the growth conditions. To obtain reproducibility of the physical properties it is therefore necessary to ensure detailed reproduction of the method of growing the crystals. The growth process was effected in a horizontal two-section tubular furnace. The second section creates a retaining temperature barrier in the path of the vapor in the capsule, improves the temperature distribution in the crystallization zone in the first section, and increases the yield of large, well-formed crystals. During the growth process the temperature fluctuations did not exceed ±5°C. (9 refs.)

81.10D Growth from solutions

109124 Preparation of III-V compounds by reduction of precursors. P.K.Gallagher, M.Robbins, F.Schrey, V.G.Lambrecht,Jr., G.Y.Chin (Bell Labs., Murray Hill, NJ, USA).
Mater. Lett. (Netherlands), vol.2, no.1, p.27-30 (July 1983).
Stoichiometric polycrystalline InP, GaAs and (InGa)As were prepared by hydrogen reduction of phosphate and arsenate precursors precipitated from aqueous solution. These ill-defined phosphate and arsenate precipitates were dried and heated at elevated temperatures in a stream of pure hydrogen to produce the phosphides and arsenides. It was found necessary to introduce elemental phosphorus or arsenic in a heated region upstream of the reaction to establish the necessary pressure of P or As in the H_2 stream to inhibit the dissociation of the newly formed InP or GaAs. (2 refs.)

109125 Kinetics of the crystallisation of barium sulphate. Effect of additives, stirring rate and barium:sulphate ratio on the rate of precipitation. E.N.Rizkalla (Faculty of Sci., Ain Shams Univ., Cairo, Egypt).
J. Chem. Soc. Faraday Trans. I (GB), vol.79, pt.8, p.1857-67 (Aug. 1983).
The kinetics of the crystallisation of barium sulphate has been studied by following the changes in ionic conductivity in supersaturated solutions containing both stoichiometric and non-stoichiometric concentrations of the lattice ions at 298K. The rate of growth showed a quadratic dependence upon the relative supersaturation which suggests a surface-controlled growth mechanism. The effect of sodium tripolyphosphate and several organic phosphonates on the growth kinetics have been studied at several additive concentrations. The retardation effect of these additives has been attributed to the simultaneous chelation of an active-site metal ion and adsorption on the surface through a phosphonate/sulphate exchange. In contrast, low concentration levels of additives such as chromate and ferrocyanide anions enhanced the rate of growth markedly. The latter effect was interpreted in terms of a dynamic adsorption/desorption mechanism. (48 refs.)

109126 Hydrothermal growth of single crystals of TeO_2 and $Te_6O_{11}Cl_2$ in the TeO_2-HCl-H_2O system. V.I.Popolitov, A.Ya.Shapiro (Inst. of Crystallography, Acad. of Sci., USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.2, p.220-3 (March-April 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.2, p.377-82 (March-April 1983). [received: Sept. 1983]
In hydrothermal conditions in the TeO_2-HCl-H_2O system with hydrochloric acid concentrations between 1 and 6 mass %, crystals of TeO_2 and $Te_6O_{11}Cl_2$ with various compositions and structures grow simultaneously from seed. A mechanism of transport of solute to the growing crystals is suggested on the basis of a study of the solubility of TeO_2 and $Te_6O_{11}Cl_2$ in aqueous solutions of HCl. (3 refs.)

109127 LDEF experiments—crystal growth by a solute diffusion process. M.D.Lind (Microelectronics R&D Center, Rockwell Internat., Thousand Oaks, CA, USA), K.F.Nielsen.
Proceedings of the 4th European Symposium on Materials Sciences under Microgravity (ESA SP-191), Madrid, Spain, 5-8 April 1983 (Paris, France: ESA 1983), p.167-74
Experiments in crystal growth by a solute diffusion process will be performed on the first flight of the NASA Long Duration Exposure Facility (LDEF) in 1984. The process to be investigated is the diffusion of two reactant solutions toward each other through a region of pure solvent in which they react chemically to form single crystals. The experiments are an extension of those performed during the Apollo-Soyuz Test Project (ASTP) and others now being developed for the first Spacelab flight. The LDEF flight will be the first space flight to satisfy completely the processing time requirements of these processes. The LDEF experiments will also incorporate precise control of the temperature, which was not possible in the ASTP experiments. The materials to be investigated are calcium carbonate, lead sulfide, and tetrathiofulvalene-tetracyanoquinodimethane (TlF-TCNQ). (5 refs.)

81.10F Growth from melts

109128 Growth and properties of large $LiNbO_3$ crystals. Liu Jin-long, Li Hui-zhang, Shi Zhong-jian, Yang Yin-lan, Weng Wen-sheng (Inst. of Acoustica, Acad. Sinica, Peking, China).
Acta Phys. Sin. (China), vol.32, no.4, p.473-80 (April 1983). In Chinese. English translation in: *Chin. J. Phys. (USA)* [received: Sept. 1983]
With the pulling direction along [0001] axis and normal of $(10\bar{1}4)$ plane, respectively, growth of large $LiNbO_3$ single crystals was achieved by using Czochralski technique. The dimensions of the crystals were 100 mm in diameter and 50 mm long. Measurements of various properties were made. The quality of these crystals was found to be uniform. Their piezoelastic-dielectric properties were the same as ordinary $LiNbO_3$ single crystals. (8 refs.)

109129 Czochralski growth of $Ba_6Ti_2Nb_8O_{30}$. H.Kuwamoto (Rockwell Internat. Sci. Centre, Thousand Oaks, CA, USA).
Mater. Lett. (Netherlands), vol.2, no.1, p.39-41 (July 1983).
$Ba_6Ti_2Nb_8O_{30}$ (BTN) single crystals have been grown by the Czochralski method under a reducing atmosphere. Crystals grown in an oxidising atmosphere were opaque polycrystals. It was found that BTN decomposes into several phases at temperatures above 1330°C. No congruent melt composition was found around stoichiometric composition in an oxygen or air atmosphere. (4 refs.)

109130 Stochastic model of the crystal growth. I. Theory and basic properties. Z.Chvoj (Inst. of Phys., Czechoslovak Acad. of Sci., Praha, Czechoslovakia).
Czech. J. Phys. Sect. B (Czechoslovakia), vol.B33, no.9, p.961-71 (1983).
The author presents a new method of the description of crystal growth from the melt in the framework of the theory of stochastic processes. This new theory is demonstrated by a very simple linear model to obtain simple and clear results and dependences of the characteristics of crystal growth on external parameters and properties of the material. (3 refs.)

109131 Versatile magnet assembly for Czochralski silicon crystal growth. K.M.Kim, G.H.Schwuttke, P.Smetana (IBM Corp., Armonk, NY, USA).
IBM Tech. Disclosure Bull. (USA), vol.26, no.2, p.601-3 (July 1983).
A versatile modular magnet assembly consisting of multiple pancake-type coils is described. (no refs.)

109132 On remeltings at the crystal growth from the melt. O.G.Nalbandyan.
Izv. Akad. Nauk Arm. SSR Fiz. (USSR), vol.17, no.1, p.21-6 (1982). In Russian.
Conditions for the appearance of remeltings are obtained for the crystal growth from the melt in the case of a conventional growth model. The characteristic times of crystallization interface inertia were determined and the interface could be taken to be noninertial, i.e. as practically instantaneously following the melting point isotherm. The macrohomogeneity of grown crystals could be achieved by stabilizing the modal picture of convective flows in the melt. (11 refs.)

109133 Preparation and properties of single crystals of some cadmium-containing indium, thallium, and cesium halides. A.V.Orinchai, V.B.Lazarev, E.Yu.Peresh, B.M.Koperl'os, V.S.D'ordyai (Uzhgorod State Univ., Uzhgorod, USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1080-6 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1281-7 (Aug. 1982).
Single crystals of the compounds $TlCdI_3$, Tl_4CdI_6, In_4CdI_6, $CsCdCl_3$, $CsCdBr_3$, Cs_2CdBr_4, and Cs_2CdI_4 were grown. Their microhardness, density, and electrical conductivity were measured and transmission and Raman spectra were recorded; the covalent component of the chemical bond was calculated (expressed in terms of the heat of atomisation). The temperature dependence of the dielectric permeability of $CsCdBr_5$ and Cs_2CdBr_4 crystals was investigated. Some laws governing the change in properties of the single crystals under study on going from Cl to Br and from In to Tl were found. (15 refs.)

109134 Recent advances and future directions in CZ-silicon crystal growth technology. G.Fiegl (Siltec Corp., Mountain View, CA, USA).
Solid State Technol. (USA), vol.26, no.8, p.121-31 (Aug. 1983).
Today's advanced micro-circuits require crystalline semiconductor materials with a very high degree of perfection. In addition, price pressures have dictated crystal diameter and melt size increases, although intrinsic material properties do not improve through mere scale-ups. New technologies have to evolve to meet the demands for the most complex devices. A first step in coping with this situation is the recent introduction of a fully computer-controlled crystal growing process, resulting in a high degree of reproducibility. The application of magnetic fields, which aid in the suppression of temperature fluctuations near the crystal melt interface, has led to further improvement towards a more homogenous material. However, inhomogeneities on a macroscopic and microscopic scale, resulting from the nonsteady state nature of the present widely used CZ batch process, can best be controlled through continuous melt replenishment. (10 refs.)

109135 Precipitation process design for denuded zone formation in CZ-silicon wafers. D.Huber, J.Reffle (Wacker Chemitronic, Burghausen, Germany).
Solid State Technol. (USA), vol.26, no.8, p.137-43 (Aug. 1983).
Modern microprocessor controlled silicon growth techniques can provide silicon materials with different tightly controlled oxygen ranges. For internal gettering purposes the precipitation rate of the interstitial oxygen is a parameter as important as the oxygen concentration itself. Fast precipitation rates, either grown into the material or generated by a low temperature preanneal can cause wafer warpage or may create a denuded zone not deep enough at the end of the device process. Materials which do not precipitate at normal process temperatures will obviously not generate internal gettering, but these materials allow the decoupling of the out-diffusion of oxygen from its precipitation. Thus, denuded zones and oxygen precipitation can be formed independently. (10 refs.)

109136 Developments in Czochralski silicon crystal growth. J.W.Moody, R.A.Frederick (Monsanto Electronic Materials Co., St. Peters, MO, USA).
Solid State Technol. (USA), vol.26, no.8, p.221-5 (Aug. 1983).
If past trends can be used as a guide, then 'bigger and better' are the watchwords for future Czochralski silicon development—bigger in the sense of larger diameter crystals from larger charge sizes; better in terms of improved homogeneity and control of impurities and defects. The economics associated with large diameter wafers and the homogeneity required for dense, fast circuits set new material specifications. Recent developments in puller-design and growth processes to meet these stringent demands of the present and future are reviewed. (7 refs.)

81.10H Zone melting and zone refining

109137 A continuous method of zone melting. A.Bryczkowski (Inst. of Chem. Processing of Coal Zabrze, Zamkoklal, Poland).
Chem. Eng. Sci. (GB), vol.38, no.8, p.1343-6 (1983).
Methods of continuous zone melting are characterized by a minor productivity in comparison to the periodical melting process—conducted under the same conditions—with the application of a multisectional system of heaters. A continuous method of repeated zone melting has been proposed which allows one to obtain higher yield compared to the one gained in an analogical periodical installation, a yield characterized by a very good equalization of the concentration of impurity in the product in case of distribution coefficient smaller than one. (6 refs.)

109138 RF plasma zone melting apparatus. Y.Kumarishiro (Electotech. Lab., Ibaraki, Japan), N.Yazawa, S.Misawa, A.Itoh.
Plasma Chem. & Plasma Process. (USA), vol.3, no.2, p.249-57 (June 1983).
The characteristics of a RF plasma for the crystal growth of nitrides with high dissociation pressures are described. The electrical behaviour measured with a new ammeter is sensitive to both gas composition and ambient pressure. A VN rod was melted under optimum conditions of 400 torr in an Ar-N_2 mixed plasma to demonstrate that the present crystals have nearly the same composition as those obtained by RF induction heating under 10 atm. of nitrogen. This is direct evidence of chemical dissociation of nitrogen from the melt being suppressed by means of the RF plasma gas. (11 refs.)

109139 Zone-melting preparation of rare earth element orthovanadate crystals. Yu.P.Udalov, Z.S.Appen (I.V. Grebenshchikov Inst. of Silicate Chem., Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1143-5 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1349-51 (Aug. 1982).
Good quality RE orthovanadate crystals may be prepared by the relatively inexpensive method of zone melting with 'dynamic' immersion by means of an iridium plate heater. The growth of RE orthovanadate crystals by zone melting is a complex combination of physicochemical incongruent evaporation and crystallization from a multicomponent Y_2O_3-V_2O_3-V_2O_5 system. The process requires careful maintenance and control of a set oxygen partial pressure. (11 refs.)

109140 Free-surface vibration of a floating zone induced by surface-tension-driven oscillating flow. C.-H.Chun, W.Wuest (DFVLR-Inst. for Experimental Fluid Mech., Gottingen, Germany), J.Siekmann.
Proceedings of the 4th European Symposium on Materials Sciences under Microgravity (ESA SP-191), Madrid, Spain, 5-8 April 1983 (Paris, France: ESA 1983), p.205-11
The interaction between the oscillating thermal Marangoni convection in a cylindrical liquid bridge heated from the upper bound and the vibration of the free surface is studied by analysing temperature oscillations due to the flow oscillation and the deflection of a laser sheet passing through the liquid bridge employing an FFT analyzer. The frequencies of the free surface vibrations are strictly the same as those of the temperature oscillations and can be clearly separated from those of the capillary waves. A physical interpretation on the shape of the free surface deformation is given. (9 refs.)

109141 Measurement of the critical Marangoni number in a floating zone under reduced gravity. D.Schwabe, A.Scharmann (I. Phys. Inst., Justus-Liebig-Univ. Giessen, Giessen, Germany).
Proceedings of the 4th European Symposium on Materials Sciences under Microgravity (ESA SP-191), Madrid, Spain, 5-8 April 1983 (Paris, France: ESA 1983), p.213-18
The oscillatory state of thermocapillary convection in floating zone is described. The results of an experiment under reduced gravity in the sounding rocket experiment TEXUS 5 are reported. The Marangoni number for the transition from laminar to oscillatory thermocapillary convection under microgravity is of the order of 9×10^3. The experiment is discussed critically. Further 1-g results are presented and discussed which will serve as the basis for analyzing forthcoming μ-g-experiments. (13 refs.)

109142 Numerical solutions of floating-zone thermocapillary flows. Being-I Fu, S.Ostrach (Dept. of Mech. & Aerospace Engng., Case Western Reserve Univ., Cleveland, OH, USA).
Proceedings of the 4th European Symposium on Materials Sciences under Microgravity (ESA SP-191), Madrid, Spain, 5-8 April 1983 (Paris, France: ESA 1983), p.239-45
A finite difference scheme is used to determine the axisymmetric flow and temperature fields in a half floating-zone configuration. The primary purpose of this study is to determine the effects of the surface-tension Reynolds number, Marangoni number, and Prandtl number on the thermocapillary flow under weightless conditions. The range of parameters considered includes those for actual growth of silicon crystals. A strongly coupled nonlinear numerical scheme and variable grid size are utilized to obtain solutions at the appropriate large ranges of parameters. The effects of buoyancy, surface heat loss, and aspect ratio are also investigated. The flows are found to form essentially a single-cell pattern with the core located nearer to the free surface. The axial velocity near the free surface is two to four times larger than near the axis. (15 refs.)

81.10J Growth from solid phases

(inc. multiphase diffusion and recrystallisation)

109143 Study of the synthesis of complex analogs of TlSe by a thermographic method. E.M.Godzhaev, M.M.Zarbaliev, K.M.Dzhafarov, V.A.Mamedov (M. Azizbekov Inst. of Petroleum & Chem., USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1178-80 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1386-8 (Aug. 1982).
The process of synthesis of chalcogen-containing compounds was studied by the method of differential thermal analysis. Thermograms of the process of synthesis were obtained on a NTR-62M brand pyrometer. At the temperature of heating of the initial mixture with composition $TlInSe_2$ (ternary analog), three exoeffects are observed—at 230, 265, and 780°C. The first two effects correspond to the temperature of formation of the compounds In_2Se and Tl_2Se; at 780°C these chalcogenides, combining with one another, form the ternary compound $TlInSe_2$. It can be suggested that the ternary compound $TlInSe_2$ is formed by bypassing the formation of a defective compound. On the thermogram of the synthesis of $TlInGaSe_3$ six exoeffects were observed at 230, 265, 620, 645, 690, and 780°C. These effects probably correspond to the temperatures of formation of the compounds In_2Se, Tl_2Se, In_2Se_2, Ga_2Se, Ga_2Se_3 and $TlInGaSe_3$. (4 refs.)

109144 A new type of regular concretion of crystals [gypsum]. G.V.Russo, T.G.Petrov (State Univ., Leningrad, USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.1, p.114-16 (Jan.-Feb. 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.1, p.196-9 (Jan.-Feb. 1983). [received: Sept. 1983]
Investigates concretions in a study of the crystallization of gypsum. To investigate the crystallization of gypsum the authors used a method based on bulk crystallization. Gypsum was formed by the reaction $CaCl_2+Na_2SO_4+H_2O \rightarrow CaSO_4.2H_2O\downarrow$. The authors used supersaturations $\Delta c/c_0$ between 0.5 and 2.0. The temperature was 22°C. 81.15 METHODS OF THIN FILM DEPOSITION

(inc. epitaxial growth methods; see also 68.55 Thin film growth, structure, and epitaxy)

109145 A new method for the fabrication of submicron thick gallium arsenide membranes. K.C.Lee, J.Silcox, C.A.Lee (Nat. Res. & Resource Facility for Submicron Structures, Cornell Univ., Ithaca, NY, USA).
Appl. Phys. Lett. (USA), vol.43, no.5, p.488-9 (1 Sept. 1983).
This letter reports a new anodic etching technique for the fabrication of submicron thick, self-limited GaAs films directly from bulk GaAs wafers, without the use of epitaxial layers as etch stops. The new etch stop mechanism used is the apparent reduction, by low dosage ion implantation, of the lifetime of defect electron states (holes) in a submicron thick layer near the surface of the wafer. Since the anodic dissolution of GaAs proceeds with the consumption of six holes per GaAs molecule dissolved, the reduction in the hole lifetimes causes a corresponding reduction in the etch rate of the implanted layer, which therefore enables the fabrication of large area submicron thick GaAs films. Evidence is also presented to show that the thickness of the membranes produced using this technique is approximately twice the projected range of the implanted ions. (8 refs.)

109146 Silver coatings obtained using a wire spraying technique. M.Ghouse, P.R.Krishnamoorthy, B.S.Mann (Materials Sci. Lab., Corporate Res. & Dev. Div., Bharat Heavy Electricals Ltd., Hyderabad, India).
Surf. Technol. (Switzerland), vol.19, no.4, p.363-71 (Aug. 1983).
Silver coatings were obtained on aluminium alloy (LM6) using a wire spraying technique and their bond strength and electrical contact resistance were measured using an Elcometer adhesion tester and a microhammeter respectively. The thickness and the surface roughness of the coatings were measured with an optical microscope and a Taylor Hobson Surtronic 3 instrument respectively; the structure and oxidation of the coatings were examined by means of a scanning electron microscope and a Philips X-ray diffractometer. The results of the present investigation reveal that there is no marked change in the bond strength of the sprayed coatings when bond coatings (Ni_3Al/Cu) are applied. The electrical contact resistance of silver coatings obtained without a bond coating seems to be lower than that for silver coatings with a bond coating. Silver coatings obtained using the wire spraying technique were not oxidized. (6 refs.)

109147 Crystallization of silicon films on glass: a comparison of methods. R.A.Lemons (Los Alamos Nat. Lab., Los Alamos, NM, USA), M.A.Bosch, D.Herbst.
Laser-Solid Interactions and Transient Thermal Processing of Materials, Boston, MA, USA, 1-4 Nov. 1982 (New York, USA: Elsevier 1983), p.581-92
The lure of flat panel displays has stimulated much research on the crystallization of silicon films deposited on large-area transparent substrates. In most respects, fused quartz is ideal. It has high purity, thermal shock resistance, and a softening point above the silicon melting temperature. Unfortunately, fused quartz has such a small thermal expansion that the silicon film cracks as it cools. This problem has been attacked by patterning with islands or moats before and after crystallization, by capping, and by using silicate glass substrates that match the thermal expansion of silicon. The relative merits of these methods are compared. Melting of the silicon film to achieve high mobility has been accomplished by a variety of methods including lasers, electron beams, and strip heaters. For low melting temperature glasses, surface heating with a laser or electron beam is essential. Larger grains are obtained with the high bias temperature, strip heater techniques. The low-angle grain boundaries characteristic of these films may be caused by constitutional undercooling. A model is developed to predict the boundary spacing as a function of scan rate and temperature gradient. (28 refs.)

81.15C Deposition by cathodic sputtering

109148 Deposition of films of zinc oxide by ion-beam sputtering. A.P.Semenov, M.V.Mokhosoev, V.D.Bazarov.
Elektron. Obrab. Mater. (USSR), no.3, p.83-5 (1983). In Russian. English translation in: *Electrochem. Ind. Process. & Biol. (GB)*
The results are given of a process of sputtering zinc oxide powder, previously sintered in the form of a tablet, by a beam of ions of inert gas. Piezoelectric films of zinc oxide on various substrates were obtained. The technological parameters influencing the quality of the films so obtained are determined. (6 refs.) *A.J.B.*

109149 Predicting conditions for sputtering gas-thermal coatings with given thickness and waviness. G.P.Lazarenko.
Izv. VUZ Mashinostr. (USSR), no.7, p.102-9 (1983). In Russian.
Data on the shaping of gas-thermal coatings sputtered onto plane surfaces and the surfaces of solids of revolution are correlated. The relationship between the mean thickness and waviness of the coating and the technological parameters appropriate for controlling the shape is described. A procedure and algorithms for predicting the conditions required for the process which will ensure the production of coatings with the required macrogeometry for machine production components are given. (4 refs.) *L.M.H.*

109150 Ion beam sputter deposition of optical coatings. J.R.Sites, P.Gilstrap, R.Rujkorakarn (Dept. of Phys., Colorado State Univ., Fort Collins, CO, USA).
Opt. Eng. (USA), vol.22, no.4, p.447-9 (July-Aug. 1983).
A beam of 500 to 1200 eV argon and oxygen ions, neutralized with an equal number of electrons, strikes a target, and the sputtered particles form a deposited layer of SiO_2, Ta_2O_5, or TiO_2. A second beam at lower energy is aimed at the substrate and used for stress modification and predeposition sputter cleaning. Deposited films are mechanically stable and extremely adherent; internal stress is compressive. The primary contaminant is carbon, which is less than one per cent. Refractive indices near 1 μm are 1.47 for SiO_2, 2.03 for Ta_2O_5, and 2.27 for TiO_2. Optical absorptance of half-wavelength films at 1.06 μm is near 10^{-4} for SiO_2 and Ta_2O_5 and near 4×10^{-4} for TiO_2. Damage tests with a 114 μm radius, 5 ns pulse length, 1.06 μm wavelength laser show an onset energy flux for visible damage in the 12 to 30 J/cm^2 range for single-layer films, and slightly less for a three-layer structure. (7 refs.)

109151 Low energy ($\leq$100 eV) sputtering of thin molybdenum nitride films. D.A.Baldwin, N.Shamir, P.Hochmann, J.W.Rabalais (Dept. of Chem., Univ. of Houston, Houston, TX, USA).
Surf. Sci. (Netherlands), vol.130, no.2, p.361-72 (Aug. 1983).
Molybdenum nitride films formed by 100 eV N_2^+ bombardment to saturation of polycrystalline Mo have been sputtered to high fluency by normally incident 100 eV Ar^+ and He^+ and 15 eV Ne^+ while the surface nitrogen concentration was monitored by Auger electron spectroscopy (AES). The penetration distance of nitrogen atoms during film formation and subsequent sputtering is assumed to be small enough that AES will detect, to some degree, all of the nitrogen in the film. The nitrogen AES signal decays exponentially to unsputterable levels for the 15 eV Ne^+ and 100 eV He^+ cases and decays bi-exponentially to near the bulk contamination level for the 100 eV Ar^+ case. The results are interpreted according to existing concepts, but the kinetics of nitrogen loss is modelled using a two-layer adaptation of the standard model for adsorbate monolayer sputtering kinetics. Fitting the proposed model to the data yields apparent cross-sections which are interpreted as composites of cross-sections for experimentally indistinguishable elementary processes; these elementary cross-sections for each process are geometrical averages on the polycrystalline surface. Processes considered, in addition to nitrogen sputtering, include bombardment-induced transport of nitrogen within the film and sputtering of the Mo lattice itself. (33 refs.)

81.15G Vacuum deposition

109152 Laterally seeded regrowth of silicon over SiO_2 through strip electron beam irradiation. Y.Hayafuji, T.Yanada, S.Usui, S.Kawado, A.Shibata, N.Watanabe, M.Kikuchi (Sony Corp. Res. Center, Yokohama, Japan), K.E.Williams.
Appl. Phys. Lett. (USA), vol.43, no.5, p.473-5 (1 Sept. 1983).
Studies the laterally seeded regrowth of polycrystalline Si film over SiO_2 islands through the use of a very narrow strip electron beam of a high-energy density. A 0.5-μm polycrystalline Si film was deposited over the entire surface of wafers on which SiO_2 islands, 30-100 μm wide and 2 cm long, had been formed. A stationary electron beam 60 μm$\times$3 cm was focused on the wafer surface with an average energy density of 0.7 MW/cm^2 at 10 kV. The wafers were irradiated for 0.1-2 ms while moving at a speed of up to 500 cm/s past the beam. A transmission electron microscopic analysis showed that the laterally seeded regrowth of Si films over SiO_2 islands were realized successfully and that the regrowth film which covered the SiO_2 islands resulted in a quasi-single-crystal film with small-angle boundaries. The average speed of the front of the lateral regrowth over the SiO_2 was estimated to be about 200 cm/s. (22 refs.)

109153 High-quality ZnSe thin films grown by molecular beam epitaxy. T.Yao, M.Ogura, S.Matsuoka, T.Morishita (Electrotech. Lab., Ibaraki, Japan).
Appl. Phys. Lett. (USA), vol.43, no.5, p.499-501 (1 Sept. 1983).
High-quality, nominally undoped, low-resistivity ZnSe thin films are grown by molecular beam epitaxy (MBE). The MBE ZnSe shows the largest peak intensity ratio of the near-band-edge emission to the deep center luminescence even at room temperature compared with other epitaxial techniques, which indicates the smallest concentration of complex defects in the MBE ZnSe. From the temperature dependence of electron mobility for MBE ZnSe, the authors obtained the mobility value as high as 6.9×10^3 cm^2/Vs. This is the highest value ever obtained in epitaxial ZnSe films and indicates the concentration of isolated charge defects as low as 1×10^{16} cm^{-3}. (18 refs.)

109154 Hydrogen in carbon foils made by DC glow discharge in ethylene. P.Bailey, D.G.Armour (Dept. of Electrical Engng., Univ. of Salford, Salford, England), J.B.A.England, N.R.S.Tait, D.W.L.Tolfree.
Nucl. Instrum. & Methods Phys. Res. (Netherlands), vol.213, no.2-3, p.517-23 (1 Aug. 1983).
Thermal deposition has been studied from thin films of carbon prepared by DC glow discharge in ethylene. The only gases released in significant quantities are hydrogen and methane. Both releases can be characterised by a continuum of activation energies but the methane release peaks at a lower temperature than that from hydrogen. The estimated total hydrogen release is compared with the hydrogen content determined by nuclear scattering experiments. Infrared studies suggest that the majority of CH_2 and CH_3 bonds can be ruptured by annealing at 300°C, a temperature well below the hydrogen and methane release rate maxima. Possible hydrogen bonding modes and desorption mechanisms are discussed. (28 refs.)

109155 Enhanced E-beam evaporation of tin. V.C.Marcotte, R.C.Martinson, K.Tautel (IBM Corp., Armonk, NY, USA).
IBM Tech. Disclosure Bull. (USA), vol.26, no.2, p.608-9 (July 1983).
The objective is to evaporate tin at a high angstrom per second rate. (no refs.)

109156 Phase composition and structure of thin praseodymium and dysprosium sulphide films. L.S.Palatnik, M.N.Naboka, A.P.Kulikov, V.Ya.Shevchenko, V.I.Sergienko, S.S.Borisova (Inst. of Chem., Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.11, p.1531-4 (Nov. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.11, p.1784-7 (Nov. 1982).
The optimum conditions for the formation of thin films of the sulfides Pr_3S_4 and Dy_2S_3 and epitaxial films of praseodymium and dysprosium monosulfides have been determined. At T_s=650-870K, praseodymium sulfide of the composition Pr_3S_4 is formed on NaCl, quartz and sapphire substrates; at $T_s\approx$670K, the layer on KCl is biphasic (Pr_3S_4+PrS); under the same conditions epitaxial layers of PrS are formed on NaCl. Biphasic layers of the

composition DyS+Dy_2S_3 are formed on KCl substrates at 620-670K. A hexagonal phase of the praseodymium oxysulfide Pr_2O_2S is formed at condensation temperatures of 870K and higher through interaction of the condensate with the residual gases (O_2 and H_2O). (12 refs.)

109157 Chemical conversion of surface and film formation techniques used together with vacuum deposition and ion implantation. M.Satou (Government Industrial Res. Inst., Osaka, Japan), F.Fujimoto.
J. Vac. Soc. Jpn. (Japan), vol.26, no.4, p.287-93 (1983). In Japanese.
An attempt was made to form a new surface layer on a substrate by concurrently performing deposition and ion injection. In this case, although the energy per ion atom was 10 to 20 keV, lower than in ordinary ion injection, the adhesion between the substrate and the new layer was excellent. This paper reports experimental conditions and results on aluminum nitride films formed using nitrogen molecular ions and aluminium as depositing atom. (13 refs.) *K.B.*

81.15H Chemical vapour deposition

109158 Hydrogenated amorphous silicon produced by laser induced chemical vapor deposition of silane. M.Meunier, T.R.Gattuso, D.Adler, J.S.Haggerty (MIT, Cambridge, MA, USA).
Appl. Phys. Lett. (USA), vol.43, no.3, p.273-5 (1 Aug. 1983).
The electronic properties of hydrogenated amorphous silicon (*a*-Si:H) produced by laser-induced chemical vapor deposition of silane are reported. Spin density and both optical gap and hydrogen content increased with decreasing substrate temperature. Electrical conductivities are reported. Film properties are superior to those produced by conventional chemical vapor deposition of silane. (22 refs.)

109159 Photodeposition of aluminum oxide and aluminum thin films. R.Solanki, W.H.Ritchie, G.J.Collins (Engng. Res. Center, Colorado State Univ., Fort Collins, CO, USA).
Appl. Phys. Lett. (USA), vol.43, no.5, p.454-6 (1 Sept. 1983).
Uniform films of Al_2O_3 have been photodeposited using an excimer laser operating at 248 nm (KrF) or at 193 nm (ArF) and trimethylaluminum and N_2O as the reactants. Deposition rates were typically 2000 Å/min and the physical, chemical, and electrical properties of the photodeposited Al_2O_3 films are comparable to films deposited using conventional techniques. Properties of photodeposited aluminum films are also presented. (22 refs.)

109160 AsH_3 to $Ga(CH_3)_3$ mole ratio dependence of dominant deep levels in MOCVD GaAs. M.O.Watanabe (Toshiba Res. & Dev. Center, Kawasaki, Japan), A.Tanaka, T.Udagawa, T.Nakanisi, Y.Zohta.
Jpn. J. Appl. Phys. Part 1 (Japan), vol.22, no.6, p.923-9 (June 1983).
Dependence of the 0.8 eV electron trap (so-called EL2) concentration on the As/Ga mole ratio during growth in MOCVD GaAs has been investigated by varying growth temperatures. It has been found that a demarcation exists in the growth temperatures, which divides two regions with different trap concentration-As/Ga mole ratio relationships. The trap concentration increases with the As/Ga mole ratio by the one-fourth power at growth temperatures of 630°C and 660°C, while it increases with the As/Ga mole ratio by the one-half power at 720°C and 740°C. Corresponding with this difference, there is a slight difference in activation energies between the materials grown at the lower temperatures and those grown at the higher temperatures. A possible explanation based on thermodynamic considerations is presented. (19 refs.)

109161 Degradation-free P-CVD SiN deposition on GaAs FETs. Y.Yamane, Y.Ishii, T.Mizutani (Musashino Electrical Communication Lab., Nippon Telegraph & Telephone Public Corp., Tokyo, Japan).
Jpn. J. Appl. Phys. Part 2 (Japan), vol.22, no.6, p.L350-2 (June 1983).
The plasma enhanced chemical vapour deposition (P-CVD) silicon nitride (SiN) effect on normally-off GaAs FETs was examined. It was verified that positive ion bombardment effect brings about GaAs FET degradation. A simple, improved method of successfully achieving damage free SiN deposition on GaAs FETs is proposed. (3 refs.)

109162 A simple reusable susceptor design for MOCVD. J.S.Roberts (Dept. of Electronic & Electrical Engng., Univ. of Sheffield, Sheffield, England).
J. Vac. Sci. & Technol. B (USA), vol.1, no.3, p.850-1 (July-Sept. 1983).
A popular research size reactor is the horizontal design described by Bass (1975) consisting of a quartz envelope and RF heated silicon carbide coated graphite susceptor. During deposition of GaAs and AlGaAs the susceptor surface and reactor walls become coated with polycrystalline material leaving a pattern of the slices on the surface of the susceptor. Subsequent growth with irregular shaped substrates invariably leads to staggering of the coated and uncoated regions of the susceptor, and multiple use results in thick uneven deposits of the residual material. Under such conditions the slice receives uneven radiative heating leading to temperature variations across the wafer. Since slice temperature is an important parameter for residual doping, dopant incorporation, and luminescence efficiency, the resulting epitaxial layer can have uneven properties. The problem of cleaning the susceptor in the absence of an HCl vapor etch has been overcome by using a specially designed susceptor with molybdenum inserts which can be easily removed and cleaned after growth. (1 ref.)

109163 Self-regulation of epitaxial growth of gallium arsenide in a chloride system. I.A.Frolov, B.L.Druz', V.E.Aver'yanov.
Inorg. Mater. (USA), vol.18, no.9, p.1241-3 (Sept. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.9, p.1456-8 (Sept. 1982). [received: Sept. 1983]
The authors have studied the characteristics of gallium arsenide eitaxy with the formation of a local polycrystalline deposit zone in the system Ga-$AsCl_3$-H_2 on the reactor walls. They observed the effect of self-regulation of the epitaxial process due to the change in the size of the gallium arsenide deposit zone on the reactor walls. (4 refs.)

109164 High conductive carbon films obtained by plasma CVD. Y.Onuma, Y.Kato (Faculty of Engng., Shinshu Univ., Wakasato, Nagano, Japan), H.Matsushima.
J. Vac. Soc. Jpn. (Japan), vol.26, no.6, p.563-70 (1983). In Japanese.
Carbon films have been prepared by RF plasma decomposition of benzene vapour, intending to obtain high conductive films at low decomposition temperature. The surface morphology, structure, IR absorption and electrical properties have been investigated. By this method, carbon films can be obtained at decomposition temperature range of 400~1000°C. Electron transmission microscopy and electron diffraction analyses show that carbon films consist of microfine particles and have graphite like structure. Increasing the decomposition temperature, the intensity of absorption corresponding to the vibration of C-H bonds tends to decrease and the resistivity of carbon films rapidly decrease, owing to the crystallization and evaporation of hydrogen. Conductivity of carbon films prepared at low decomposition temperature rapidly increasing the ambient temperature as like semiconductor. On the other hand, carbon films prepared at high decomposition temperature show weak dependence of conductivity on the ambient temperature like narrow gap semiconductors and have p type conduction. (20 refs.)

109165 Procedure of growing thin CdS specimens free from surface contamination for TEM observation. H.Iwanaga, T.Yoshiie.
Solid State Phys. (Japan), vol.18, no.5, p.265-6 (May 1983). In Japanese.
The essential points in producing clean vapor-grown crystals are (1) to utilize a one-side sealed quartz tube, (2) rapid cooling of the furnace and (3) evacuation of the growth zone after the growth. (4 refs.)

109166 Heteroepitaxial growth of CdTe on GaAs by laser assisted deposition. J.T.Cheung, M.Koshnevisan (Rockwell Internat. Sci. Center, Thousand Oaks, CA, USA), T.Magee.
Appl. Phys. Lett. (USA), vol.43, no.5, p.462-4 (1 Sept. 1983).
The heteroepitaxial growth of (111) CdTe on (100) GaAs substrates has been obtained by laser assisted deposition at 350°C. Films 5-14 μm thick were characterized by X-ray diffraction, UV reflectance measurement, and transmission electron microscopy. Results indicate good crystallinity with 10^5 cm^{-2} dislocation densities beyond a few microns from the CdTe/GaAs interface. (7 refs.)

109167 Preparation and oxidation of a thin Ba film. A.Shih, G.A.Haas, C.R.K.Marrian (Naval Res. Lab., Washington, DC, USA).
Appl. Surf. Sci. (Netherlands), vol.16, no.1-2, p.93-105 (May-June 1983). (3rd Tri-Service Cathode Workshop, Fort Monmouth, NJ, USA, 23-26 March 1982).
A method of determining the thickness of vapor-deposited thin Ba films is described. The thickness is expressed in terms of numbers of Ba monolayers which were defined and characterized on W (100) and Ir (100) substrates using low energy electron diffraction (LEED) and Auger electron spectroscopy (AES). The changes in the electronic properties of a 10-layer Ba film on Ir (100) during oxidation were studied using low energy electron reflectivity (LEER) measurements. When the oxidation of Ba was nearly complete (as shown by AES), the LEER patterns were similar to that found for a randomly oriented BaO layer with perhaps a partial layer of Ba on the surface. Additional O_2 exposure, however, resulted in the formation of a BaO crystal whose characteristic LEER patterns were similar to that found for a randomly oriented BaO layer with perhaps a partial layer of Ba on the surface. Additional O_2 exposure, however, resulted in the formation of a BaO crystal whose characteristic LEER patterns indicated a Fermi level position which suggested a high density of oxygen-vacancy donors and whose large electron affinity indicated nonstoichiometry at the surface. Further O_2 exposure resulted in a BaO-type surface dipole and oxygen vacancy donor densities more typical of BaO lattices. At this level of oxidation, a minimum work function of 1.4 eV was attained, which was identical to that of an active thin BaO film. Furthermore, AES indicated a Ba to O ratio identical to that of a BaO film. Any change from this stoichiometry through the addition of either oxygen or barium resulted in an increase in the work function. (15 refs.)

109168 Properties of plasma-deposited films using ethylene and fluoroethylenes as starting monomers. T.F.Retajczyk,Jr., P.K.Gallagher (Bell Labs., Murray Hill, NJ, USA).
Mater. Lett. (Netherlands), vol.2, no.1, p.23-6 (July 1983).
Some properties of plasma-deposited films using each of the members of the ethylene and fluoroethylene series of the general formula $C_2H_NF_{4-N}$ (N=0-4) as starting monomers, under otherwise identical deposition conditions, were determined as a function of the fluorine/carbon ratio of the starting monomer. These included film stoichiometry, deposition rate, film stress, hydrophobicity, dielectric constant ($\epsilon \approx 2.6$-3.7), dielectric strength (>200 V/μm), and thermal stability. (6 refs.)

109169 Production of layers of $A^{IV}B^{VI}$ compounds with specific parameters by quasi-closed-volume methods. D.M.Freik (Ivano-Frankovskii State Pedagogic Inst., USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1041-52 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1237-48 (Aug. 1982).
Layers of $A^{IV}B^{VI}$ compounds and their solid solutions are obtained by quasi-closed-volume methods ('hot-wall' and gas-dynamic vapour flow deposition) using an auxiliary chalcogen source. (32 refs.)

81.15L Deposition from liquid phases (melts and solutions)

109170 Liquid phase growth of epitaxial Ni and Co silicides. R.T.Tung, J.M.Gibson, D.C.Jacobson, J.M.Poate (Bell Labs., Murray Hill, NJ, USA).
Appl. Phys. Lett. (USA), vol.43, no.5, p.476-8 (1 Sept. 1983).
Epitaxial Ni and Co silicides have been fabricated using pulsed laser melting and ultrarapid solidification techniques. Interfacial instabilities and cell formation are suppressed during the liquid phase epitaxy by melting mono or disilicide layers. Single crystal $NiSi_2$ and $CoSi_2$ films have been grown on (100) and (111) Si. This method does not require ultrahigh vacuum deposition or reaction techniques. (10 refs.)

109171 High-efficiency GaP pure green light-emitting diodes of 555 nm fabricated by new liquid phase epitaxy method. T.Kawabata, S.Koike (Semiconductor Div., Matsushita Electronics Corp., Kyoto, Japan).
Appl. Phys. Lett. (USA), vol.43, no.5, p.490-1 (1 Sept. 1983).
A new liquid phase epitaxy (LPE) method, which can control impurity concentration by volatilization of impurities from the growth solution under reduced pressure, has been developed. Using this LPE method, high-efficiency GaP pure green light-emitting diodes, of which the peak wavelength is 555 nm, has been obtained. The average efficiency for an epoxy-encapsulated diode is 0.1% and the maximum efficiency is 0.14% at 16 A/cm^2. (5 refs.)

109172 Chemical deposition of SiO_2 on InP. P.A.Bertrand, P.D.Fleischhauer (Chem. & Phys. Lab., Aerospace Corp., El Segundo, CA, USA).
J. Vac. Sci. & Technol. B (USA), vol.1, no.3, p.832-6 (July-Sept. 1983).
Chemical deposition experiments were performed to determine how surface preparation and film deposition conditions influence the resulting insulator-semiconductor interface composition and chemical structure. Silicon dioxide layers were chemically deposited on indium phosphide by hydrolyzing silicon orthopropoxide. On unoxidized, etched surfaces, coverage was always patchy. On InP with approximately one monolayer of chemisorbed oxygen in a hydrated-phosphate like environment, a continuous, ~60-Å-thick SiO_2 film was formed at room temperature. SiO_2 attached to the substrate through about one monolayer of Si-O-P bonds. Heating to 50°C during hydrolysis resulted in a mixed Si-In-P oxide, owing to simultaneous hydrolysis and oxidation processes. (13 refs.)

109173 Growth of epitaxial $Cd_xHg_{1-x}Te$ layers from mercury solutions of Cd and Te. Ya.F.Dub, V.I.Ivanov-Omskii, V.K.Ogorodnikov (A.F. Ioffe Phys. Tech. Inst., Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1072-5 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.,* vol.18, no.8, p.1271-4 (Aug. 1982).
Epitaxial $Cd_xHg_{1-x}Te$ layers on CdTe substrates can be obtained by liquid epitaxy from mercury solutions. At high degrees of supersaturation of the solution ($\Delta t > 3$°C), the constitutional supercooling on the crystallisation front can be prevented by introducing a temperature gradient $Gl > 8$ deg/cm. The gradient of the composition across the thickness of a layer increases with increasing supercooling. The variation of the composition across the thickness of a layer is caused mainly by diffusion processes. (01 refs.)

109174 Choice of solvent for liquid-phase epitaxy of $Ga_xIn_{1-x}As_yP_{1-y}$ solid solutions. A.A.Selin, V.N.Vigdorovich, V.P.Batura (Inst. of Electronic Technol., Moscow, USSR).
Inorg. Mater. (USA), vol.18, no.9, p.1248-51 (Sept. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.,* vol.18, no.9, p.1464-7 (Sept. 1982). [received: Sept. 1983]
An examination of the heterogeneous equilibria in the Ga-In-As-P system has shown that crystallization of $Ga_xIn_{1-x}As_yP_{1-y}$ solid solutions can be brought about over practically the whole range of compositions, from melts having compositions corresponding to the In-GaAs-GaP-InAs-InP concentration pyramid. The growth of epitaxial layers of solid solutions isoperiodic with indium phosphide or gallium arsenide must be carried out from melts having compositions within the In-GaAs-InAs-InP concentration tetrahedron (with $x \geq 0.85$, in the case of isoperiodicity with gallium arsenide, the In-GaAs-GaP-InP concentration tetrahedron has to be used). (10 refs.)

109175 Production of high-strength nickel coatings by pulse electrolysis. V.A.Zabludovskiy, Yu.V.Krivusha, N.A.Kostin.
Russ. Metall. (GB), no.2, p.54-7 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.2, p.58 (1982).
The structure of galvanic nickel coatings obtained with a unipolar pulse current was studied; an increase in pulse-current amplitude density leads to formation of a defective structure. The change in structure greatly affects the physico-mechanical properties of the nickel coatings. (8 refs.)

109176 Experimental studies of laterally seeded recrystallized, polysilicon on silicon dioxide. S.Banerjee (Coordinated Sci. Lab., Univ. of Illinois, Urbana, IL, USA), B.G.Streetman.
UGIM-83 Proceedings. 1983 University/Government/Industry Microelectronics Symposium, College Station, TX, USA, 25-27 May 1983 (New York, USA: IEEE 1983), p.79-83
Zone melting recrystallization using a scanning graphite strip heater has been employed to prepare device quality single crystal silicon films on silicon dioxide covered silicon substrates. The films contain low angle grain boundaries at about 25 μm intervals. These have a negligible effect on dopant activation and carrier mobilities in ion implanted films. Planar p-n junctions fabricated in these films have slightly higher leakage than similar junctions in bulk silicon, apparently due to intersection of the low angle grain boundaries with the junction. The results indicate, however, that device quality films on insulating substrates can be conveniently grown by zone melting recrystallization. (9 refs.)

109177 Lateral epitaxial growth of thick polysilicon films on oxidized 3-inch wafers. G.K.Celler, McD.Robinson, D.J.Lischner, T.T.Sheng (Bell Labs., Murray Hill, NJ, USA).
Laser-Solid Interactions and Transient Thermal Processing of Materials, Boston, MA, USA, 1-4 Nov. 1982 (New York, USA: Elsevier 1983), p.575-80
In the technique of lateral epitaxial growth over oxide (LEGO), crystallization is initiated at seeding was in SiO_2 and propagates over the amorphous insulator, resulting in high structural quality of the grown film. Uniform and bow-free crystallization of complete 3-inch wafers occurs in <60 sec in a special furnace, with wafers placed between a bank of high intensity tungsten halogen lamps and a water cooled base. The authors provide further details of crystallization procedure and new structural characterization data. The mechanism of LEGO crystallization and its limitations are also discussed. (8 refs.)

81.20 OTHER METHODS OF PREPARATION OF MATERIALS

109178 Electrochemical synthesis of photoactive MoS_2. L.F.Schneemeyer, U.Cohen (Bell Labs., Murray Hill, NJ, USA).
J. Electrochem. Soc. (USA), vol.130, no.7, p.1536-9 (July 1983).
The growth of polycrystalline films and single crystals of molybdenum disulfide by electrolytic reduction of a sodium tetraborate-sodium fluoride melt containing molybdenum trioxide and sodium sulfate has been examined and physical properties of those deposits studied. Polycrystalline n-type MoS_2 is readily obtained from a melt at 800°C while larger single-crystals are obtained if the melt temperature is 900°C. MoS_2 is a semiconductor with bandgap well matched to the solar spectrum and with unusual resistance to photoelectrochemical corrosion. Electrochemically-grown single crystals and polycrystalline films were employed as photoanodes in aqueous iodide-triiodide electrolytes under ~40 mW/cm^2 tungsten-halogen illumination. Open-circuit photopotentials of ~150 mV were observed for polycrystalline MoS_2. For single crystal electrolytic MoS_2 an open-circuit photopotential of 210 mV and ~2 mA/cm^2 short circuit current were reached. The use of electrochemical methods to prepare these materials offers the advantages of relatively low growth temperatures, controlled thickness, and excellent adaptability to producing large-area films inexpensively. 81.20E Powder techniques, compaction and sintering

109179 Investigation of the sintering process of NiO from the point of view of its electronic structure. M.M.Ristich, D.Ch.Stefanovich, L.F.Pryadko.
Bull. Acad. Serbe Sci. & Arts Cl. Sci. Tech. (Yugoslavia), no.20, p.1-13 (1982). In Russian.
Investigates the changes in density, microstructure and electronic properties of NiO during pressing and sintering processes. The experimental studies were conducted in a wide interval of pressing pressure which influence the stoichiometry of NiO powder and which was studied by measuring the electrical conductivity of pressed samples. The experimental data were used to calculate the changes in the electronic structure of NiO during sintering. (23 refs.)
V.G.P.

109180 Particle growth mechanisms in fluidised bed granulation. I. The effect of process variables. P.G.Smith, A.W.Nienow (Dept. of Chem. & Biochem. Engng., Univ. Coll. London, London, England).
Chem. Eng. Sci. (GB), vol.38, no.8, p.1223-31 (1983).
Two types of product granule have been identified in an experimental study of batch fluidised bed granulation; agglomerates which consist of two or more, and usually several, initial particles; and layered granules, which consist of single primary particles with dried feed material adhering to the surface. Increasing the excess fluidising gas velocity, in the range $U\text{-}U_{mf}$=0.15-0.525 m s^{-1}, resulted in decreased particle growth rates and, depending upon the binder material, a change in product morphology from agglomerates to layered granules. Similar changes resulted from increasing the mean size of the starting material. Thus, a mechanism of particle growth is proposed in which the strength of inter-particle bridges and the extent of fluid drag and inertial forces on particles determine the equilibrium granule form and size. (21 refs.)

109181 Particle growth mechanisms in fluidised bed granulation. II. Comparison of experimental data with growth models. P.G.Smith, A.W.Nienow (Dept. of Chem. & Biochem. Engng., Univ. Coll. London, London, England).
Chem. Eng. Sci. (GB), vol.38, no.8, p.1233-40 (1983).
For pt.I see ibid., vol.38, p.1223-31 (1983). Growth data from batch granulation experiments have been fitted to simple geometrical models. Layered granule growth approximates to concentric coating of core particles with binder, although the actual mechanism of growth is different. In the case of agglomeration, a relationship is established between mean granule size and binder content. (5 refs.)

109182 Localized particle fracture during compression of materials expected to undergo plastic deformation. G.R.B.Down (Pharmacy Res. & Dev., Merck Frosst Canada Inc., Pointe Claire-Dorval, Quebec, Canada).
Powder Technol. (Switzerland), vol.35, no.2, p.167-9 (July-Aug. 1983).
When powders are compressed in a die during tablet making, various stages of compaction occur, starting with rearrangement of the powder to its closest packing, followed by eventual plastic deformation or brittle fracture. Scanning electron microscopy has been utilized to further characterize all stages of compression. It is shown that materials, such as sodium chloride, which undergo eventual plastic deformation undergo some form of fracture during

the earlier stages of compaction due to the creation of high localized stresses acting on individual particles. (5 refs.)

109183 Application of critical state to uniaxial compaction. N.G.Stanley-Wood, A.M.Abdel Karim (Postgraduate School of Powder Technol., Univ. of Bradford, Bradford, England).
Powder Technol. (Switzerland), vol.35, no.2, p.185-93 (July-Aug. 1983).
From the radial stress σ_R and the normal stress σ_A, measured continuously during uniaxial loading and unloading on three compactable (sodium chloride, polyethylene and tartaric acid) and two non-compactable (polypropylene and polystyrene plastics) materials, characteristic compaction profiles of $(\sigma_A-\sigma_R)$ versus $(\sigma_A+\sigma_R)$ can be observed. The uniaxial loading stress pathways for both compactable and non-compactable materials validated the assumption that the Coulomb yield criterion, which is usually applicable for the shear testing of soils, can be applied to the uniaxial compression of particulate materials. In addition, the unloading stress profiles for the compactable materials produced two characteristic parameters: a normal stress value at zero shear $(\sigma_A+\sigma_R)_0$ and a minimum shear stress value $(\sigma_A\text{-}\sigma_R)_{\min}$. (15 refs.)

109184 Dislocation-activated solid-phase sintering. W.Schatt, E.Friedrich (Tech. Univ. Dresden, Dresden, Germany).
Z. Metallkd. (Germany), vol.74, no.8, p.489-93 (Aug. 1983). In German.
The integral dislocation densities measured by means of the positron annihilation spectroscopy on compacts of electrolytic copper powder in dependence on the sintering temperature and sintering time as well as the shrinkage and shrinkage velocity evaluated under the same conditions on identical samples lead to the conclusion that the dislocation multiplication in the course of sintering (self-activation) constitutes a general phenomenon of one-component sintering. In the stage of intensive shrinkage obviously, it is a necessary condition for a rapid material transport which is effected by particle sliding at simultaneous shape accommodation. (14 refs.)

81.20G Specific metals and alloys (compacts, pseudoalloys)

109185 The metallurgy and applications of beryllium. C.V.Sundaram, C.M.Paul, B.P.Sharma (Metall. Div., Bhabha Atomic Res. Centre, Bombay, India).
Trans. Indian Inst. Met., vol.35, no.2, p.171-92 (April 1982). [received: Aug. 1983]
Beryllium metal by virtue of its unique combination of physical, mechanical and nuclear properties is an attractive choice for specific functions in selected areas of modern engineering. At the same time, on account of the limited ductility of cast beryllium, the effective harnessing of the metal for structural applications has posed a challenge to the metallurgists over the years. During the past decade, however, there has been considerable progress in beryllium metal technology, and new grades of beryllium having superior strength and ductility have been developed. Improvement in the purity and morphology of the metal powder through electrorefining and impact attritioning techniques, and the emergence of hot isostatic pressing technology have been the major breakthroughs. As a result powder metallurgy beryllium products close to theoretical density with reduced microporosity and good three dimensional ductility are now available for structural applications. Physical metallurgy developments have been concerned with optimising microstructural features—grain size, dislocation density and beryllium oxide particle size and volume fraction—through control of specific impurities, micro-alloy additions and thermomechanical treatments. For critical applications where toughness and ductility comparable to other light alloys are required, new beryllium-aluminium alloys have been developed. Considerable headway has also been made in the metal forming and joining techniques. (88 refs.)

109186 Microcrystalline iron-base alloys made using a rapid solidification technology. R.Ray, V.Panchanathan (Marko Materials Inc., North Billerica, MA, USA), S.Isserow.
J. Met. (USA), vol.35, no.6, p.30-6 (June 1983).
Initial results of investigation on selected iron-base alloys using a rapid solidification powder metal technology are reported. The various alloys studied include commercial precipitation hardenable (PH) stainless steels, iron-aluminide-base alloys and high-speed steels. These alloys were modified with specific amounts of boron and processed by melt spinning as rapidly solidified powders followed by hot extrusion. The consolidated alloys were subjected to various heat treatment procedures for optimum mechanical properties. A 30-35% improvement in tensile strength combined with good ductility has been achieved in boron modified PH stainless steel compared to the conventional alloys. Rapidly solidified Fe-Al-B alloys show high specific strength and modulus of elasticity in the temperature range 1000-1400°F. The other noteworthy attributes of the iron-aluminide-base alloys are outstanding oxidation resistance, good low-cycle fatigue strength and high thermal stability at elevated temperatures. Very high elongations, typically up to 280%, were achieved in these alloys at high temperatures (1600°F), indicating the possibility of superplastically hot forming these materials. A rapidly solidified boron-modified tool steel showed significant improvement in tool life in cutting (turning) tests, compared to its commercial counterpart. (6 refs.)

109187 Structure and properties of rapidly solidified 7075 P/M aluminum alloy modified with nickel and zirconium. P.K.Domalavage, N.J.Grant (Dept. of Materials Sci. & Engng., MIT, Cambridge, MA, USA), Y.Gefen.
Metall. Trans. A (USA), vol.14A, no.8, p.1599-606 (Aug. 1983).
Aluminum alloy 7075 was modified by additions of 1.1 wt.% nickel and 0.8 wt.% zirconium, rapidly solidified by ultrasonic gas atomization, canned, cold compacted, hot extruded, and evaluated in terms of structure and properties. Significant improvements in tensile strength (627 MPa YS and 680 MPa UTS) and crack growth rates were realized, along with a decrease in fracture toughness (23.7 MPa $\sqrt{m}$) while maintaining ductility (10% elong.) as compared to nominal I/M 7075 behavior. A variety of experiments was performed to evaluate effects on strength, ductility, and on structure. The variables were: power size distribution, extrusion ratio, extrusion profile, different size fractions from the same lot of powder, and different locations of test bars in the several extrusions. Tensile properties, toughness, and fatigue properties were not importantly influenced by the location of test bars in the cross section or length of rectangular extruded bars. A comparison of mechanical properties from extruded bars prepared from -53 μm powders vs. 53 to 250 μm powders showed a small loss of ductility and fatigue stress for 10^7 cycles for the fine poweder product. (13 refs.)

109188 Possibilities of deoxidation of molybdenum with manganese and metals of the iron group. A.M.Bogomolov, Yu.S.Kim, L.V.Navalikhin.
Russ. Metall. (GB), no.1, p.35-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.39-42 (1982).
Introducing up to 0.8 wt.% Mn into molybdenum reduces its hardness and lowers the total concentration of oxygen in specimens. On alloying molybdenum with manganese and metals of the iron group, only oxide phases of manganese with a composition close to MnO_2 can be formed in the matrix. For the deoxidation of molybdenum, alloying with manganese is preferable to alloying with metals of the iron group. (16 refs.)

109189 On the local grain growth in WC/Co cemented carbides. T.Schmitt, M.Schreiner, E.Lassner, B.Lux (Inst. fur Chem. Technol. Anorganischer Stoffe, Tech. Univ. Wien, Wien, Austria).
Z. Metallkd. (Germany), vol.74, no.8, p.496-9 (Aug. 1983). In German.
It was shown that coarse polycrystalline WC particles, present in fine-grained WC powders can induce local grain growth during sintering with cobalt. This phenomenon is illustrated by mixing fine-grained WC/Co powders with 4 wt.% coarse Mo_2C. Grain growth of the coarse particles was revealed by elemental distribution of Mo and W in the crystals and as a result of the different etching behaviours of coarse WC crystals with and without Mo. The mechanism was identified as a solution-reprecipitation process phenomenologically similar to Ostwald ripening. The actual grain growth process, preceded by particle disintegration, is succeeded by grain shape accommodation. (18 refs.)

81.20J Dispersion-,fibre-, and platelet-reinforced metal-based composites

109190 Metallic composite materials and microgravity. L.Froyen, A.Deruyttere (Dept. Metaalkunde, Katholieke Univ. Leuven, Leuven, Belgium).
Proceedings of the 4th European Symposium on Materials Sciences under Microgravity (ESA SP-191), Madrid, Spain, 5-8 April 1983 (Paris, France: ESA 1983), p.31-6
Interfacial phenomena such as wetting, formation of a compound, diffusion between the metallic matrix and the dispersed phase play a crucial role for the fabrication process and for the final product properties of metallic composite materials. Therefore the wetting behaviour of the material systems Al-SiC and Cu-SiC has been investigated. The interpretation of the TEXUS 6-samples and the concept of the forthcoming space experiments during the TEXUS 7 and SPACELAB 1 flights are based on these results. (9 refs.)

81.20L Ceramics and refractories

109191 Ceramics from polymer pyrolysis, opportunities and needs—a materials perspective. R.W.Rice (Naval Res. Lab., Washington, DC, USA).
Am. Ceram. Soc. Bull. (USA), vol.62, no.8, p.889-92 (Aug. 1983).
Past work on polymer pyrolysis is reviewed. The opportunities, as well as some of the needs, for making several important non-oxide ceramics by polymer pyrolysis are presented. Compositions already achieved, as well as others that may be feasible, are discussed, along with expected limitations due to density considerations. Possible applications and expected microstructures are also reviewed. (33 refs.)

109192 Special heat-resisting materials from organometallic polymers. S.Yajima (Tohoku Univ., Ibaraki-ken, Japan).
Am. Ceram. Soc. Bull. (USA), vol.62, no.8, p.893-8, 903, 915 (Aug. 1983).
From organometallic polymers special heat-resisting materials are obtained by heat treatment. Organometallic polymers made in the author's laboratory are two kinds of polycarbosilanes and two kinds of polyborosiloxanes. These polymers are converted into SiC ceramics by heat treatment. A polycarbosilane is formed into a fiber and it is heated up to 1300°C, so that a SiC fiber with high tensile strength is obtained. This polymer is also promising as a binder for sintered SiC powders. Various heat-resisting materials obtained using organometallic polymers and their characteristics are described. (22 refs.)

109193 Polysilastyrene: phenylmethylsilane-dimethylsilane copolymers as precursors to silicon carbide. R.West, L.D.David, P.I.Djurovich, H.Yu (Univ. of Wisconsin, Madison, WI, USA), R.Sinclair.
Am. Ceram. Soc. Bull. (USA), vol.62, no.8, p.899-903 (Aug. 1983).
Cocondensation of phenylmethyl-$SiCl_2$ and dimethyl-$SiCl_2$ with sodium metal in toluene leads to copolymers of the formula $[(Me_2Si)_x(PhMeSi)]_n$ where $x=0.6$ to 1.4 (polysilastyrene). Synthesis and some physical properties are described for the polymer, which can be molded, cast into films or drawn into fibers. Exposure of the solid polymer to ultraviolet light leads to crosslinking. The crosslinked polymer can be thermolyzed to silicon carbide by heating above 800°C in an inert atmosphere. (22 refs.)

109194 Polycarbosilane precursors for silicon carbide. C.L.Schilling,Jr., J.P.Wesson, T.C.Williams (Union Carbide Corp., Tarrytown, NY, USA).
Am. Ceram. Soc. Bull. (USA), vol.62, no.8, p.912-15 (Aug. 1983).
One-step preparations of tractable polycarbosilanes are achieved through silicon-carbon bond-forming reactions of vinylic or chloromethyl ($ClCH_2^-$) silanes. These polymers are directly convertible to silicon carbide compositions by atmospheric pressure pyrolysis. Backbone branching is recognised as essential for practical conversion of such polycarbosilanes to silicon carbide. (16 refs.)

109195 Preparation and properties of monolithic and composite ceramics produced by polymer pyrolysis. B.E.Walker,Jr., R.W.Rice, P.F.Becher, B.A.Bender, W.S.Coblenz (Naval Res. Lab., Washington, DC, USA).
Am. Ceram. Soc. Bull. (USA), vol.62, no.8, p.916-23 (Aug. 1983).
A survey of a number of available compounds showed a general trend for measurable-to-good ceramics yields from pyrolysis to more ofen be associated with cage, phenyl, unsaturated ring and unsaturated chain structures, than with precursors having saturated bonds and metal constituents contained mainly in side groups. More detailed studies were performed on selected polymers giving yields of compounds of interest, e.g. some giving ~60% yields of SiC. Retention of some structural integrity and measurable strengths especially in composites suggests that production of small pieces of bulk ceramics, and especially ceramic composites is feasible by such processing. Electron microscopy of pyrolysis products shows most porosity to be quite fine, e.g. 0.05 to 0.5 μm and grain structure to be also be very fine, e.g. 0.1 to 0.3 μm and possibly truly absent in some cases. (9 refs.)

109196 Hot isostatic pressing in ceramics. K.Hunold (Elektroschmelzwerk Kempten GmbH, Kempten, Germany).
CFI-Ceram. Forum Int. Ber. Dtsch. Keram. Ges. (Germany), vol.60, no.5-6, p.182-9 (30 July 1983). In German, English.
A survey of possible applications for hot isostatic pressing (HIP) in connection with ceramic materials is presented. Several sample applications are examined for the purpose of indicating the advantages and disadvantages of the process for the compaction of special ceramics and pointing out some economic aspects in a comparison with conventional manufacturing methods. (22 refs.)

109197 Preparation and strength of forsterite-zirconia ceramic composites. Shen Yangyun, R.J.Brook (Dept. of Ceramics, Univ. of Leeds, Leeds, England).
Ceram. Int. (Italy), vol.9, no.2, p.39-45 (1983).
Forsterite ceramics, toughened with zirconia inclusions, have been prepared by heat treating mixtures of zircon and magnesia. The ceramics have been sintered both with and without applied pressure. The extent of reaction, the fraction of tetragonal zirconia and the density of the product materials have been determined. The strength has been measured in 3 point bend tests. Owing to the fact that the rate of reaction is faster than the rate of pore removal during pressureless sintering suitable microstructures have not been prepared by this technique. However, hot pressing yields dense, fully reacted, materials with 35% of the zirconia present in the tetragonal form; these materials have strengths (>350 MPa) substantially greater than those of conventional forsterite ceramics. (10 refs.)

109198 Synthesis of alumina and zirconia fibers. P.A.Vityaz, I.L.Fyodorova, I.N.Yermolenko, T.M.Ulyanova (Powder Metall. Res. Inst., Minsk, Belorussian SSR).
Ceram. Int. (Italy), vol.9, no.2, p.46-8 (1983).
The results of investigations of conversions occurring during synthesis of aluminum oxide and zirconium dioxide porous fibres with alloying additions in the temperature range from 20 to 1300°C are presented. The analysis of the experimental results enabled features typical for pyrolitic conversion and sintering of aluminum oxide—and zirconium dioxide—base ceramic fibres to be revealed. (1 ref.)

109199 Densification of silicon nitride powder with various additives. S.K.Bhattacharya, A.C.D.Chaklader (Dept. of Metall. Engng., Univ. of British Columbia, Vancouver, Canada).
Ceram. Int. (Italy), vol.9, no.2, p.49-52 (1983).
Cold compaction behavior of a sub-micron size silicon nitride powder with additives has been studied at various loading rates up to about 450 MPa. Liquid lubricants are found to be more effective than the solid lubricants. A marked increase in relative density has been obtained with the aid of 10 weight percent polyethyleneglycol after surface treatment of the powder with a dispersant solution. The loading rate between 0.8 and 800 MPa per minute has no effect on the densification process. Results are analysed with various theoretical equations available in the literature. The Cooper and Eaton's equation (1962) and also its modified form are used to determine the mechanism of densification during cold compaction. (11 refs.)

109200 Influence of precipitation procedure on sinterability of Y_2O_3 prepared from hydroxide precursor. M.D.Rasmussen, G.W.Jordan, M.Akinc, O.Hunter,Jr., M.F.Berard (Dept. of Materials Sci. & Engng., Iowa State Univ., Ames, IA, USA).
Ceram. Int. (Italy), vol.9, no.2, p.59-60 (1983).
The sinterability of Y_2O_3 prepared from reverse strike hydroxide precursors was found to be highly dependent on final pH and precursor dewatering procedure, high pH recursors yielding poorly-sinterable oxides if oven dried, but quite sinterable oxides if dewatered either by acetone-toluene-acetone or controlled-humidity treatments. Direct strike hydroxide precursors yielded highly-sinterable Y_2O_3 regardless of final pH or dewatering procedure. (9 refs.)

109201 The use of molten magnesium chloride in the preparation of crystalline ceramic powders. E.I.Cooper, D.H.Kohn (Dept. of Chem., Technion-Israel Inst. of Technol., Haifa, Israel).
Ceram. Int. (Italy), vol.9, no.2, p.68-72 (1983).
The interaction of molten $MgCl_2$ with various oxides and oxide minerals is described. Within several hours, at temperatures of 700-1100°C, components such as oxides of Fe, K, Ca and—under proper conditions—Ti are largely converted into the corresponding chlorides, the more volatile of which evaporate, the others being extracted into the liquid phase. By proper choice of stoichiometry, crystalline cordierite, forsterite, enstatite and spinel could be prepared; they contained a total <0.2% of oxides of Na, K, Ca and Fe, and their average-diameter range was usually 1-10 μm (or larger for forsterite). The preparation of other microcrystalline powders in molten $MgCl_2$ is briefly discussed. (32 refs.)

109202 Synthesis of iron-dispersed carbons by pressure pyrolysis of divinylbenzene-vinylferrocene copolymer. S.-I.Hirano, T.Yogo, H.Suzuki, S.Naka (Synthetic Crystal Res. Lab., Nagoya Univ., Nagoya, Japan).
J. Mater. Sci. (GB), vol.18, no.9, p.2811-16 (Sept. 1983).
Versatile carbons with finely dispersed iron were synthesized by pressure pyrolysis of a copolymer prepared from divinylbenzene and vinylferrocene at temperatures below 680°C and pressures of 125 MPa. The pyrolysis conditions of the copolymer were found to influence the final morphology of carbons to give fibrils, spheres and polyhedra. The resulting carbons contained uniformly fine particles of cementite (Fe_3C) which were less than 30 nm in size, whereas the magnetite was dispersed in the carbon matrix by pressure pyrolysis in the presence of water. Highly dispersed cementite in carbon was found to decompose into metallic iron by further heat treatment above 850°C. Porous spherulitic carbons were also synthesized by heat treatment of magnetite containing carbon spherulites. (8 refs.)

109203 Preparation of Mn-Zn ferrites having a low temperature coefficient of permeability. P.K.Gallagher, E.M.Gyorgy, D.W.Johnson,Jr., M.Robbins, E.M.Vogel (Bell Labs., Murray Hill, NJ, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.C110-11 (July 1983).
Substitutions of Ge, and to a lesser extent Ga, for Zn in manganese-zinc ferrite were found to increase the initial permeability (μ) from ≈200 to ≈1000. The relative temperature coefficient of permeability is very low (<0.02%) over the range −40° to +80°C. These desired properties are achieved without controlling the atmosphere during sintering and subsequent cooling provided that the atmosphere contains ≥1 vol% O_2. (3 refs.)

109204 Effect of chemical composition on the sinterability of ultrafine SiC powders. J.Hojo, K.Miyachi, Y.Okabe, A.Kato (Dept. of Appl. Chem., Kyushu Univ., Fukuoka, Japan).
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.C114-15 (July 1983).
Ultrafine β-SiC powders with an average particle size of 0.01 to 0.06 μm were produced by CVD methods. When these powders contained enough carbon to remove impurity oxygen, sintered bodies with a relative density >95% were achieved at 2050°C in the presence of 1 wt% boron. The Vickers microhardness reached 21 to 25 GPa at a density of ≈95%. (6 refs.)

109205 Mechanism and kinetics of formation of ferrite in the solid phase in the CaO-Fe_2O_3 system [Mossbauer observations]. T.Ya.Malysheva, V.Ya.Lyadova, V.V.Korovushkin, I.V.Ostrovskaya.
Russ. Metall. (GB), no.1, p.5-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.6-9 (1982).
The authors' study of the kinetics and mechanism of ferrite formation in the solid state in the CaO-Fe_2O_3 system indicated that in a charge of any composition, the primary phase is monocalcium ferrite. Dicalcium ferrite is formed by the reaction between monocalcium ferrite and calcium oxide. That formed in charges at low temperatures and retention times is the reaction product of the heterogeneous charge where the reaction of ferrite formation is limited only by the diffusion of the substance in the solid state and is independent of the kinetics of sintering. In the temperature range studied (up to 900°C) semicalcium ferrite is not formed in the system. In the charge of the corresponding composition monocalcium ferrite and hematite are the only reaction products. (10 refs.)

109206 The effect of MnO_2 and La_2O_3 additions on the sintering of $Pb(Zr,Ti)O_3$ solid solutions. T.Kala (Res. Inst. of Electrotech. Ceramics, Hradec Kralove, Czechoslovakia).
Silikaty (Czechoslovakia), vol.27, no.3, p.193-8 (1983).
The study revealed a substantial effect of non-compensated charged defects resulting from the presence of heterovalent admixtures of MnO_2 and La_2O_3 oxides, on the final microstructure following the sintering of solid solutions based on $Pb(Zr,Ti)O_3$. Solid solutions of $PB(Zr,Ti)O_3$ containing excess of charged point defects were found to be capable of sintering up to about 98% of theoretical density. On the other hand, solid solutions based on $Pb(Zr,Ti)O_3$ free from heterovalent admixtures, or with electrically compensated admixtures of acceptor or donor type, showed extensive grain growth at sintering and were virtually uncapable of being sintered to an apparent density exceeding 95% of theoretical density. (15 refs.)

109207 Use of emanation thermal analysis in the evaluation of sinterability of ceramic powders. V.Balek (Inst. of Nuclear Res., Rez, Czechoslovakia).
Silikaty (Czechoslovakia), vol.27, no.3, p.257-69 (1983). In Czech.
Emanation thermal analysis (ETA) was used for characterizing the initial stages of sintering of ferric oxide (α-Fe_2O_3) and thorium dioxide. ETA, which is based on measuring the rate of release of radon from radioactive-labelled samples, was shown to follow sensitively in particular the changes in surface area during the initial stages of sintering, and changes in the microstructure of samples resulting from their densification at higher temperatures. The behaviour of thorium dioxide (ex-oxalate) during non-isothermal heating up to 1100°C in air is described. On the basis of ETA curves obtained from isothermal heating of powdered ThO_2 at 705, 735, 780 and 825°C, the kinetics of the changes in surface area has been characterized. The kinetics of sintering of powdered α-Fe_2O_3 during non-isothermal heating at the respective rates 2.5, 5, 10 and 16°C/min was characterized by means of ETA curves. The sintering process is characterized by decreasing emanating power E. The apparent activation energy of the sintering process, calculated from the experimental curves, is $Q=214.2$ kJ/mole. 109208 Corundum ceramics with reduced sintering temperatures. A.M.Cherepanov, T.V.Solov'eva, F.Ya.Kharitonov, I.V.Gorshkova, R.F.Tyrina (All-Union Inst. of Electrical Ceramics, USSR).
Glass & Ceram. (USA), vol.39, no.9-10, p.504-6 (Sept.-Oct. 1982). Translation of: *Steklo & Keram. (USSR)*, vol.39, no.10, p.19-20 (Oct. 1982).
Investigates a new composition for corundum ceramic with a reduced sintering temperature, possessing rather high physical and engineering properties, including corrosion resistance to molten aluminum. The main source of material consisted of technical alumina grade GK containing 90% α-Al_2O_3 (GOST 6912-74). Glass-forming additives in the form of fluorite (CaF_2) and talc from the Alguisk deposits were added. Analysis of the fired results showed that the best properties were possessed by specimens containing 7% glassy additive, fired at 1650°C. (3 refs.)

109209 Study of comparative characteristics of adhesional strength of epoxide resins on the basis of sulfone and bis-phenol A. R.K.Benzal, K.Keshav.
Vysokomol. Soedin. Ser. A (USSR), vol.25, no.8, p.1772-4 (Aug. 1983). In Russian. English translation in: *Polym. Sci. USSR (GB)*
Epoxide resins of various MM have been synthesized from epichlorohydrin and 4,4′-sulfonyldiphenol and from epichlorohydrin and bis-phenol A. These resins were cured at high temperature by four various crosslinking agents including aliphatic and aromatic amines. For each case the adhesional strength was measured. The adhesional strength of both types of epoxide resins was shown to be higher when curing by aromatic amines. The adhesional strength of sulfone-containing resin was lower than that of the resin obtained from bis-phenol A. (2 refs.)

109210 Adhesion of graphite fibres to epoxy matrices. I. The role of fibre surface treatment. L.T.Drzal (Air Force Wright Aeronaut. Labs., Wright-Patterson Air Force Base, OH, USA), M.J.Rich, P.F.Lloyd.
J. Adhes. (GB), vol.16, no.1, p.1-30 (1983).
The authors' study has combined fibre surface chemistry, morphology, interfacial strength measurements and fracture characterisation in order to elucidate the role of surface treatments. The results of this investigation lead to the conclusion that surface treatments designed to promote adhesion to epoxy matrix materials operate through a two-part mechanism. First, the treatments remove a weak outer fibre layer initially present on the fibre. Second surface chemical groups are added which increase the interaction with the matrix. (37 refs.)

109211 Carbon-reinforced thermoplastics: what they offer, how to process them. S.R.Gerteisen, S.D.Gerbig (Wilson-Fiberfil Internat., Neshanic Station, NJ, USA).
Plast. Eng. (USA), vol.39, no.1, p.39-42 (Jan. 1983).
Carbon-fiber-reinforced thermoplastics are emerging as engineering materials superior in key properties to glass-reinforced thermoplastics and no more difficult for experienced GRTP molders to process. With little doubt, CFRTPs will be a significant part of the molding trends of the 1980s. (no refs.)

81.30 PHASE DIAGRAMS AND MICROSTRUCTURES DEVELOPED BY SOLIDIFICATION AND SOLID-SOLID PHASE TRANSFORMATIONS

(see also 61. Structure of liquids and solids 64.70 Phase equilibria, phase transitions, and critical points)

109212 Cementite decomposition in steel under plastic deformation. G.N.Gridnev, V.G.Gavrilyuk (Inst. of Phys. of Metals, Acad. of Sci., Kiev, Ukrainian SSR).
Phys. Met. (GB). Translation of: Metallofizika, Kiev (USSR), vol.4, no.3, p.531-51 (1982). [received: Aug. 1983]
Investigations of the state of cementite in cold-worked pearlitic steel are reviewed and summarized. Thermomagnetic analysis, electron microscopy, and Mossbauer spectroscopy data point to a partial decomposition of cementite in steel subjected to plastic strain. The extent of decomposition may be as great as several tens of percent and depends on the interfacial area and the concentration of alloying elements. Thermodynamically, decomposition is attributed to the fact that the binding energy of carbon atoms and dislocations in ferrite exceeds the heat of solution of cementite. Possible mechanisms of decomposition are considered, and the largest contribution to the process is found to be due to the strain-promoted mass transport of carbon from the surface layers of cementite to dislocations at the interfae. The distribution of carbon among different types of defects is analyzed, and the effect of original structure on the magnetization-temperature curves is shown to be fairly well explicable on the assumption that in the process of cementite decomposition some of the carbon atoms get into microcracks and form graphite during subsequent heating. (58 refs.)

109213 Effect of repeated plastic deformation on the state of the carbide phase in steels. M.V.Belous, V.B.Novozhilov (Polytech. Inst., Kiev, Ukrainian SSR).
Phys. Met. (GB). Translation of: Metallofizika, Kiev (USSR), vol.4, no.3, p.552-6 (1982). [received: Aug. 1983]
The effect of repeated plastic deformation on the state of the carbide phase in steels was examined by thermomagnetic analysis and transmission electron microscopy. Preliminary plastic deformation and recrystallization annealing were found to prevent the carbide phase decomposition during subsequent plastic deformation. This is attributed to the formation of graphite film around retained carbide particles. (10 refs.)

109214 The high pressure disproportionation of Spinel $MgAl_2O_4$. R.A.Howald, A.Moe, B.N.Roy (Dept. of Chem., Montana State Univ., Bozeman, MT, USA).
High Temp. Sci. (USA), vol.16, no.2, p.111-21 (April 1983). [received: Sept. 1983]
The thermodynamic properties of prericlase, corundum, and spinel are known with sufficient accuracy to calculate equilibrium pressures for the reaction $MgAl_2O_4(c)=MgO(c)+2\ AlO_{1.5}$ (c, corundum) as a function of temperature. The shape of the calculated equilibrium line is quite sensitive to the details of the equations of state used for the various materials. The authors have tested a new computer program with calculations on this system, and find that it provides a good test for proposed equations of state. Murnaghan's logarithmic equation of state (1944) is satisfactory provided both the bulk modulus and its pressure derivative are functions of the temperature. Full equations of state are given in equations and tables for all three solids. The P-T phase diagram calculated with these values differs substantially from that of Liu (see High Temp. High Press., vol.12, p.217, 1980). Depending on the thermodynamic values selected for $MgAl_2O_4$, the equilibrium line is near $9000+1.11(T-1000)$ of $9700+1.50(T-1000)$. (33 refs.)

109215 A percolation model for the two-phase zone of alloys. V.A.Zhuravlev, V.V.Chetvertnykh, N.V.Fedorova, V.P.Podshivalov, S.R.Gallyamov.
Russ. Metall. (GB), no.2, p.117-20 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.131-3 (1982).
A percolation mode has been derived for the two-phase zone of alloys with random and correlated phase distributions in the zone, and a computer implementation is described. The presence of percolation thresholds in the zone was established, with a scaling dependence of the permeability. (4 refs.)

109216 Studies on copper-nickel-tellurium system. Mrityunjaya Singh, S.Bhan (Dept. of Metall. Engng., Inst. of Technol., Banaras Hindu Univ., Varanasi, India).
Trans. Indian Inst. Met., vol.35, no.6, p.548-51 (Dec. 1982). [received: Aug. 1983]
The ternary isotherm at 470°C in the copper-nickel-tellurium system has been worked out by X-ray diffraction technique. In the Ni-Te binary system only two intermetallic compounds viz. Ni_3Te_2 and $NiTe_{1+x}$, the latter with a large homogeneity range extending up to $Ni_{55}Te_{45}$, are found stable at the temperature of investigation. In the Cu-Te binary system only Cu_2Te phase is found stable at 470°C. In the ternary system the existence of two phases viz. $Cu_{55}Ni_5Te_{40}$ and another around the composition $Cu_{20}Ni_{42}Te_{38}$ has been established. The structure of $Cu_{55}Ni_5Te_{40}$ has been found related to (B8)Ni_2In type with $a=3.95_1$ Å and $c=10.72_3$ Å. The $Cu_{20}Ni_{42}Te_{38}$ phase has been indexed on the basis of a face centred cubic lattice with $a=11.54_6$ Å. Density measurements have indicated that the f.c.c. phase contains 80 atoms per unit cell. The $NiTe_2$ phase is found to have a large homogeneity range in the ternary system. (17 refs.)

109217 Kinetics of growth of phases by mutual diffusion in three-component multiphase metallic systems. V.I.Gryzunov, G.V.Shcherbedinskii, E.M.Sokolovskaya, B.K.Aitbaev, A.S.Sagyndykov (M.V. Lomonosov State Univ., Moscow, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.194-7 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The published phase diagrams of various three-component systems were considered, especially the phase diagram of Ti-Ni-Co alloys at 1000°C. A theoretical analysis of the results indicated that the dimensions of a growing phase depended on the mutual diffusion coefficients, relationships between these coefficients, and concentrations of various elements at the boundary of the new phase. (9 refs.) *A.T.*

109218 Phase equilibria in iron ternary alloys. X. Critical evaluation of constitution of cobalt-iron-vanadium system. G.V.Raynor, V.G.Rivlin (Dept. of Metall. & Materials, Univ. of Birmingham, Birmingham, England).
Int. Met. Rev. (GB), vol.28, no.4, p.211-27 (1983).
For pt.IX see ibid., vol.28, no.1, p.23 (1983). Available experimental evidence on the constitution of the Co-Fe-V system has been critically reviewed. A projection of the liquidus surfaces is recommended, involving primary separation of the γ-phase (solid solution of Fe and V in Co), the α-phase (solid solution of Co and V in the $\alpha\delta$Fe-phase of the Fe-V system), and the σ-phase. Isothermal sections, partial in some cases, are presented for temperatures ranging from 1300° to 900°C, and emphasize the importance of the σ-phase. No ternary compounds have been reported. In alloys with less than 20% V which are subject to the γ/α transformation on cooling or heating, an approach to equilibrium is only obtained after very long annealing treatments, and diagrams are therefore given for both equilibrium and non-equilibrium conditions at approximately 600°C. In view of its importance, the course of the γ/α transformation in alloys poor in V is also reviewed. (29 refs.)

109219 On the study of austenite stabilization in the Cr13%Ni4-6% steels. J.Svejcar, J.Hubackova, V.Cihal, K.Mazanec (VUT, Brno, Czechoslovakia).

Kovove Mater. (Czechoslovakia), vol.21, no.4, p.353-63 (1983). In Czech.

Deals with the study of chemical heterogeneity and structural stability of the phases, coexisting in the structure of the Cr13%Ni4-6% steels, during tempering in the intercritical temperatures region. From the evaluation of potentiokinetic polarization curves it follows that under the given conditions the microregions with a different content of basic alloying elements originate in the matrix. The electron microanalysis of the present phase proved the significant nickel enrichment of austenite with a simultaneous nickel content decrease in the martensitic matrix. No changes in the chromium content could be found. The structural stability of austenite, originating at the intercritical temperatures tempering is determined not only by its nickel enrichment, but also by its morphology and, particularly by the dimensions of the austenitic regions (their thickness should not be greater than 0.15-0.25 μm). (9 refs.)

109220 Phase equilibria and kinetics in the solid state reaction between silicon and NiCrAl. E.L.Hall, R.L.Mehan, M.R.Jackson (Corporate Res. & Dev. Center, General Electric Co., Schenectady, NY, USA).

Metall. Trans. A (USA), vol.14A, no.8, p.1549-60 (Aug. 1983).

The result of the solid state reaction of silicon with a model superalloy consisting of 70 at.% Ni, 20 at.% Cr, and 10 at.% Al at 900°C is examined using light microscopy, electron microprobe analysis, and analytical electron microscopy. Extensive reaction is observed, with the formation of seven distinct reaction zones. The crystallography and chemistry of the phases present in each zone are determined using the analytical electron microscope. The reaction paths are described with reference to binary and ternary phase equilibrium diagrams. The kinetics of the reaction are presented. The nature and extent of the reaction are compared with previous experiments in which silicon carbide and reaction-bonded Si-SiC were reacted with the model superalloy. (17 refs.)

109221 A correlation of the thermodynamic properties and phase diagram of the system lead-silver using a Gaussian plus subregular formalism. J.D.Esdaile, N.G.Siviour (Div. of Mineral Engng., CSIRO, Clayton, Victoria, Australia).

Metall. Trans. A (USA), vol.14A, no.8, p.1707-12 (Aug. 1983).

A method of correlating with precision the thermodynamic properties and phase boundaries of the lead-silver system is described. This employs a Gaussian plus subregular formalism for the liquid phase and uses Henrian behaviour for the solid phases, which have minor extents of solid solubility. The experimental liquidus data obtained by using the high shear technique of Esdaile and Siviour (see ibid., vol.10, p.382-4, 1979) are tabulated and also compared with the requirements of the phase diagram, leading to a mean temperature difference of 0.43K for the silver-rich side and 0.017K for the lead-rich side, between measured and calculated liquidus and solidus data. For the high temperature liquidus data of Heycock and Neville (1897) the mean temperature difference is 2.2K. The calculated compositions of the solid lead and silver phases below the eutectic point are also compared with the experimental measurements. (17 refs.)

109222 Nitrogen solutions in liquid iron alloys. L.A.Bol'shov.

Russ. Metall. (GB), no.1, p.22-5 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.1, p.23-5 (1982).

Interaction coefficients at constant concentration ratios, B_i^j, have been considered which correspond to concentrations expressed in mole fractions and the use of natural logarithms. A relation connecting the interaction parameters at constant concentration ratios, B_i^j and b_i^j has been obtained. Two methods for the theoretical estimation of interaction coefficients at constant concentration ratios have been proposed for nitrogen in iron alloys. Values of the B_N^j interaction coefficients at constant concentration ratios have been calculated for nitrogen with alloying transition metals (Ni, Co, Mn, Cr, Mo, W, V, Nb and Ta) in melts of Kh18N8 steel at 1600°C. (9 refs.)

109223 Activity of arsenic and tin in Fe-As-Sn melts. V.M.Chumarev, V.M.Sholokov, A.I.Okunev.

Russ. Metall. (GB), no.1, p.26-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.1, p.26-8 (1982).

The distribution of tin and arsenic between Fe-As-Sn melts and lead at 1623K has been studied. From the distribution data the activity coefficients of tin are calculated. The calculated vales of the activity of tin have large positive, and those of arsenic negative, deviations from Raoult's law. The interaction parameter ϵ_{Sn}^{As} was found to be 2.4. (11 refs.)

109224 Interaction of additions of vanadium and copper with admixture atoms of iron in α-Zr [Mossbauer observations]. V.V.Igrushkin, V.G.Kirichenko, I.A.Petel'guzov, V.V.Chekin.

Russ. Metall. (GB), no.1, p.74-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.1, p.87-91 (1982).

Analysis of the Mossbauer absorption spectra of iron containing phases of alloys based on α-Zr, containing up to 1% admixtures of Fe, Fe-V and Fe-V-Cu, state diagrams of binary Zr-Fe, Zr-V and Zr-Cu systems, coefficients of distribution of admixtures and crystal structures of intermetallides of these systems, leads to a conclusion that in the ternary Zr-Fe-V and quarternary Zr-Fe-V-Cu system, the iron containing intermediate phase forms on the basis of the intermetallide ZrV_2. (11 refs.)

109225 Examination of phase equilibrium in Ti-Al-Zr-W-Mo alloys. M.A.Volkova, T.T.Nartova, E.V.Meleshko.

Russ. Metall. (GB), no.1, p.114-16 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.1, p.130-2 (1982).

A partial polythermal section of the Ti-Al-Zr-Mo-W system with a constant content of 6% Al, 7% Zr and 3% W was constructed. The section is characterised by the presence of the α, β and δ(W) solid solutions. The alloys of the given section solidify as the β solid solution and one cooling from 1040°C and lower undergo transformation in the solid state associated with the $B \rightarrow \alpha+\beta \rightarrow \alpha+\beta+\delta(W) \rightarrow \alpha+\delta(W)$ transformation. (7 refs.)

109226 Solubility of various metals in solid sodium and potassium. B.N.Aleksandrov, N.V.Dalakova.

Russ. Metall. (GB), no.1, p.117-21 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.1, p.133-40 (1982).

A method of preparation of dilute alloys based on sodium in the range of concentrations 5×10^{-4}-1 at.% without carrying our a quantitative analysis, was developed. Using the method of the residual electrical resistance, the solubility limit C_{lim} was either determined (as for K, Rb, Cs, Cd, Hg, Inm Sn, Pb, Ti) or evaluated (as for Sr, Ca, Li) for 12 admixtures in solid sodium. It is shown that the solubility of K, Li, Tl, Rb, Hg in sodium is sufficiently high (0.75-0.05 at.%) and for the remaining metals is low (0.01-2×10^{-4} at.%); for Sn and Pb, C_{limit} increases with an increasing temperature of annealing and for Hg, Cd and Tl—it decreases. (20 refs.)

109227 Examination of quasibinary sections of the Mg-Al-Sr system. M.M.Makhmudov, A.V.Vakhobov, T.D.Dzjurayev.

Russ. Metall. (GB), no.1, p.122-4 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.1, p.141-3 (1982).

It has been shown that the Mg-Al-Sr ternary system contains five quasibinary sections. All the examined sections are eutectic with limited miscibility. (6 refs.)

109228 Construction of the T-P-N state diagram of the Co-C system at pressures up to 100 kbar. T.P.Ershova, D.S.Kamenetskaya, L.P.Il'ina.

Russ. Metall. (GB), no.1, p.130-7 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.1, p.153-61 (1982).

A thermodynamic calculation of the equilibrium lines of the T-P-N state diagram of the Co-C system, taking into consideration equilibria with diamond and carbide Co_3C, were carried out to a pressure of 100 kbar. The T-N cross-sections of the T-P-N state diagram of this system at pressures of 1 atm, 60 and 100 kbar, and projections of the temperatures and concentrations of the characteristic points of the diagram on to the T-P and N-P planes, were constructed. (15 refs.)

109229 The Zr-Fe phase diagram (0-66.6 at.% Fe). T.O.Malakhova, A.N.Kobylkin.

Russ. Metall. (GB), no.2, p.187-91 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.2, p.205-9 (1982).

Zr-Fe alloys containing from 0.2 to 66.6 at.% Fe were examined. The specimens were prepared from iodide zirconium of 99.68%. Examination of the system by X-ray phase and microstructural analysis confirms the existence of Zr_3Fe formed by the peritectoid reaction $\beta+Zr_3Fe \rightleftharpoons Zr_3Fe$; the temperature of formation of Zr_3Fe was also found, about 885°C. Zr_2Fe (tetragonal, $a=6.384$ Å, $c=5.598$ Å, $c/a=0.877$) decomposes eutectoidally: by the reaction $Zr_2Fe \rightleftharpoons Zr_3Fe+ZrFe_2$, at about 775°C. DTA was used to determine the $\alpha \rightleftharpoons \beta$ transformation temperature in alloys with 0-25 at.% Fe, the temperature of the eutectic $liq \rightleftharpoons \beta+Zr_2Fe$ and the peritectic $liq+ZrFe_2 \rightleftharpoons Zr_2Fe$ equilibria (928 and 974°C, respectively). The results from all three methods were used to plot the Zr-Fe phase diagram for 0-66.6 at.% Fe. (10 refs.)

109230 Thermodynamic properties of solid U-Sb alloys. V.A.Lebedev, V.I.Pyatkov, L.V.Khalturin.

Russ. Metall. (GB), no.2, p.192-4 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.2, p.210-12 (1982).

A new variant of the EMF method was used to determine the thermodynamic properties of solid U-Sb alloys in the range 750-900 Å. (6 refs.)

109231 The Nb-Ga-Cu phase diagram (superconducting compounds). V.M.Pan, V.I.Latysheva, O.G.Kulik, V.V.Gorskiy.

Russ. Metall. (GB), no.2, p.195-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.2, p.213-17 (1982).

The isothermal section of the Nb-Ga-Cu system was constructed for 800°C, and the phase equilibria were examined in cast and annealed alloys. The existence was confirmed of the ternary Laves phase NbCuGa and the ternary sigma phase Nb_2CuGa. A new ternary χ-phase was detected, composition 57 at.% Nb, 25 at.% Ga, 18 at.% Cu. (10 refs.)

109232 Structure and properties of rapidly cooled (superconductive) Pb-Bi alloys. E.M.Savitskiy, Yu.V.Efimov, G.Yenn, I.Shtapf.

Russ. Metall. (GB), no.3, p.84-7 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.,* no.3, p.93-9 (1982).

The microstructure, phase composition and certain properties of Pb-Bi alloys after their quenching from the liquid state are studied under various conditions. The amorphous state is not fixed when Pb-Bi melts are cooled at rates of 10^4-10^8 K/s from 423-1273 to 77-293K. Metastable compounds (X and Y), only formed with super-fast cooling to nitrogen temperatures, are not stable on tempering. Super-fast cooling to 293K leads to an increase in the mutual solubility of components, a shift of the ϵ-phase composition from 27-42 to 20-50 at.% Bi, a sharp refinement of the structural constituents and the change in properties associated with these manifestations (to a rise in T_k, J_k, χ and HV). (10 refs.)

109233 On the origin of increasing hydrogen pressures in the two solid phase regions of intermetallic compound-hydrogen systems. W.A.Oates (Dept. of Metall., Univ. of Newcastle, Shortland, NSW, Australia).

Scr. Metall. (USA), vol.17, no.8, p.983-6 (Aug. 1983).

A new and quite general explanation of 'sloping plateau pressures' in alloy-hydrogen systems is presented. Three possible transformation modes for the ternary Ab_x-H systems during the phase transformation from low hydrogen concentration (α-phase) to high hydrogen concentration (β-phase) are discussed. (11 refs.)

109234 Cu-Ti and Cu-Ti-Al solid state phase equilibria in the Cu-rich region. J.-Y.Brun (Inst. Nat. Polytech. de Grenoble, Grenoble, France), S.-J.Hamar-Thibault, C.-H.Allibert.

Z. Metallkd. (Germany), vol.74, no.8, p.525-9 (Aug. 1983).

Solid state phase equilibria of Cu-rich Cu-Ti and Cu-Ti-Al alloys have been determined by composition and structure analysis of the phases present in samples annealed at 850, 800, 700, and 600°C. Orthorhombic Cu_4Ti exists in equilibrium with a Cu solid solution, the Ti content of which largely increases with temperature. A low temperature Cu_4Ti structure modification is found to be tetragonal body centered. In Cu-rich ternary alloys, 4 phase domains are found: Cu solid solution, $Cu+Cu_4Ti$, $Cu+Cu_2TlAl$, and $Cu+Cu_4Ti+Cu_2TiAl$. The Ti limit content of the ternary Cu phase increases with temperature. Cu_4Ti does not extend in the ternary system. (24 refs.)

109235 Constitution of the binary Pd-Si system in the concentration range from 0 to 33.3 at.% Si. H.Langer, E.Wachtel (Max-Planck-Inst. fur Metallforschung, Stuttgart, Germany).

Z. Metallkd. (Germany), vol.74, no.8, p.535-44 (Aug. 1983). In German.

The palladium-silicon phase diagram has been newly established applying thermoanalytical (MTA, DTA), metallographic and X-ray methods. In the concentration range from 0 to 33.3 at.% Si, besides the stable and the glass system (MS-I), two further metastable systems can be characterized, the constituents of which are formed from melt as a consequence of well defined cooling rates. MS-I: $\dot{T}>10^4$ $Ks^{-1} \rightarrow$ amorphous state ($15<c_{Si}<23$ at.%). MS-II: $10^2<\dot{T}<10^4$ $Ks^{-1} \rightarrow$ the following intermetallic phases are occurring: $Pd_{5.25}Si$ (16 at.% Si) and $Pd_{4.5}Si$ (18.18 at.% Si). MS-III: $\dot{T}<10^2$ $Ks^{-1} \rightarrow$ the formation of the $Pd_{4.5}Si$ intermetallic phase is suppressed. In this concentration range, the Pd_5Si (16.67 at.% Si) and Pd_4Si (20 at.% Si) phases belong to the stable system. (49 refs.)

109236 Phase diagrams under irradiation. K.C.Russell (Dept. of Materials Sci. & Engng., MIT, Cambridge, MA, USA).

Alloy Phase Diagrams. Proceedings of a Symposium, Boston, MA, USA, Nov. 1982 (New York, USA: North-Holland 1983), p.365-74

The high intensity irradiation environments produced by advanced fast fission and proposed fusion reactors, high voltage electron microscopes, and heavy ion accelerators add a new dimension to materials science. Typical irradiations of alloys in these devices introduce the order of 10^8 J/mol displacement energy in the form of vacancy-interstitial (Frenkel) pairs. Although most of this energy is dissipated as heat during Frenkel pair recombination, significant amounts may be harnessed to produce microstructural change, hence changes in the phase diagram. The author discusses the various atomistic mechanisms available to convert irradiation energy to microstructural change and cites selected experimental observations where the various mechanisms are operative. (31 refs.)

109237 Effect of concentration gradient on phase stability. K.N.Tu, U.Gosele (IBM Thomas J. Watson Res. Center, Yorktown Heights, NY, USA).
Alloy Phase Diagrams. Proceedings of a Symposium, Boston, MA, USA, Nov. 1982 (New York, USA: North-Holland 1983), p.375-6
Summary form only given. A feature of thin film reaction that is different from the reaction in bulk samples is the tendency to form a single intermetallic compound rather than all of them which are allowed according to the equilibrium phase diagram. For example, in thin film silicide formation, Pd_2Si has been found to form along and to grow as a layer between Pd and Si. The silicide is stable over a wide temperature range of 100 to 700°C. The phenomenon of single intermetallic compound growth is not unique to silicide formation between transition metal films and silicon, but is also commonly observed in reactions between bimetallic thin films. The phenomenon indicates phase stability. Analysis of the kinetics of layered compound growth in thin film reactions follows more or less the same analysis which has been developed for bulk diffusion couples. The basic equation of growth can be represented by $\dot{x}=k_1f(\Delta G)$ where $\dot{x}$ is the growth rate, k_1 is the rate constant (or mobility) and $f(\Delta G)$ is the driving force which in general is a function of free energy change of the system. When the driving force is a first order gradient term across the layer, a parabolic growth is obtained and frequently it is observed in the so-called 'diffusion limited' growth. When the driving force is constant, a linear growth is obtained and observed in the so-called 'interface reaction limited' growth. (8 refs.)

109238 The Au-Pb phase diagram. D.S.Evans, A.Prince (Hirst Res. Centre, GEC plc, Wembley, England).
Alloy Phase Diagrams. Proceedings of a Symposium, Boston, MA, USA, Nov. 1982 (New York, USA: North-Holland 1983), p.383-8
The Au-Pb system has been redetermined using DTA, metallography and X-ray techniques. The compounds Au_xPb, $AuPb_2$ and $AuPb_3$ are generated by peritectic reactions at 434°, 253° and 221.5°C respectively. $AuPb_3$ and Pb form a eutectic at 84.8 at.% Pb and 212°C. It is confirmed that Au_2Pb is stable down to at least 200°C. (12 refs.)

109239 The In-Sn phase diagram. D.S.Evans, A.Prince (Hirst Res. Centre, GEC plc, Wembley, England).
Alloy Phase Diagrams. Proceedings of a Symposium, Boston, MA, USA, Nov. 1982 (New York, USA: North-Holland 1983), p.389-94
The In-Sn system has been redetermined using DTA, metallography and X-ray diffraction techniques. It is confirmed that the β and γ intermediate phases are formed by peritectic reactions, at 141.0° and 222.6°C respectively. β and γ form a eutectic at 47.4 at.% Sn and 119°C. The kink in the γ-phase solidus proposed by Heumann and Alpaut (see J. Less-Common Met., vol.6, p.108-17, 1964) is not confirmed. (9 refs.)

109240 Phase equilibria in the Ni-rich region of the Ni-Al-Zr system. C.S.Jayanth, P.Nash (Dept. of Metall. & Materials Engng., Illinois Inst. of Technol., IL, USA).
Alloy Phase Diagrams. Proceedings of a Symposium, Boston, MA, USA, Nov. 1982 (New York, USA: North-Holland 1983), p.395-8
Alloys from the Ni-rich corner of the Ni-Al-Zr system have potential for use in high temperature, high strength applications. Such applications require a detailed knowledge of the high temperature phase equilibria. In the case of the Ni-Al-Zr system no isothermal sections have been published although the existence of a monovariant eutectic valley between Ni_3Al and Ni_7Zr_2 has been established. An experimental determination of the phase equilibria in this system is being carried out using quantitative electron microprobe analysis (JEOL JSM-U3), X-ray diffraction and optical metallography. Partial isothermal sections are being determined for 1373K (1100°C) and 1273K (1000°C) and the resulting phase equilibria compared to that in the Ni-Al-Hf system determined previously. (10 refs.)

109241 Phase equilibria at 1173K in the Ni-Ti-Al system. W.W.Liang (Gas Res. Inst., Chicago, IL, USA), P.Nash.
Alloy Phase Diagrams. Proceedings of a Symposium, Boston, MA, USA, Nov. 1982 (New York, USA: North-Holland 1983), p.399-401
In order to provide some consistent data over a substantial range of composition an experimental determination of the phase equilibria at 1173K and from 0-50 atomic % Al is being carried out. The main experimental technique being used is quantitative electron microprobe analysis (JEOL 733) by wavelength dispersive X-ray spectrometry. In addition, X-ray diffraction is being used to establish the structures of phases present and optical metallography of cast structures to determine the fields of primary crystallization. In addition to establishing the phase equilibria at the temperature the composition range for the existence of the $AlNi_2Ti$ phase is being determined. The results thus far are compared with previous experimental data and calculated isothermal sections. (5 refs.)

109242 Cu-Pb-Sn ternary system: low Cu additions to Pb-Sn- binary system. V.C.Marcotte (IBM General Technol. Div., Hopewell, Junction, USA), K.Schroder.
Alloy Phase Diagrams. Proceedings of a Symposium, Boston, MA, USA, Nov. 1982 (New York, USA: North-Holland 1983), p.403-10
A portion of the Cu-Pb-Sn ternary diagram was determined experimentally. The investigation was concentrated on the high Pb corner and, to a lesser extent of alloys from Sn to the binary Pb-Sn eutectic. The experimental techniques used were thermal analysis, metallography, and electron microprobe analysis. A new technique for determining liquidus temperatures was used. For the high Pb region the proposed ternary eutectic at 0.06 Cu 0.02% SnPb (all compositions are in weight %) was not observed. For most alloys the primary crystallization phase was Cu_3Sn. It was shown the primary crystallization phase was Cu_3Sn. It was shown that Cu_6Sn_5 exists in the solid state; for high Sn alloys, it was observed that the addition of Pb reduced the decomposition temperature of Cu_6Sn_5. A ternary eutectic reaction near the binary Pb-Sn eutectic was confirmed, and the temperature of the ternary eutectic was 1K below that of the binary eutectic. (7 refs.)

109243 Modification of Al-Si microstructure—the Al-Si-Sr phase diagram from 0-20 wt.% Si and 0-5.0 wt.% Sr. M.D.Hanna, A.Hellawell (Dept. of Metall. Engng., Michigan Technol. Univ., Houghton, MI, USA).
Alloy Phase Diagrams. Proceedings of a Symposium, Boston, MA, USA, Nov. 1982 (New York, USA: North-Holland 1983), p.411-16
It is well known that the morphology of primary and eutectic silicon resulting from solidification is sensitive to minor impurity additions: 'modification' by alkali and alkaline earth metals is common foundry practice and the use of strontium is of recent and current interest because its effect is retained in liquid metal for relatively long times. The mechanism for modification remains obscure and is not necessarily the same from one elemental addition to the next, but it is essential to separate the equilibrium and kinetic influences if the phenomenon is to be better understood. Accordingly, the liquidus surface and eutectic reactions have been located in the relevant part of the Al-Si-Sr system by careful thermal analysis and the results correlated with the microstructure. Comparison is made with the parallel behavior of alkali metal additions. (11 refs.)

109244 Alloy chemical comparison of the refractory metal—noble metal phase diagrams T_5-T_{10} (T_5=V, Nb, Ta; T_{10}=Pd, Pt). R.Waterstrat (American Dental Assoc. Health Found. Res. Unit., NBS, Washington, DC, USA), B.C.Giessen.
Alloy Phase Diagrams. Proceedings of a Symposium, Boston, MA, USA, Nov. 1982 (New York, USA: North-Holland 1983), p.423-8
The six T_5-T_{10} metal alloy phase diagrams containing Pd or Pt have now all been established. The alloy phases occurring in these systems are tabulated and reviewed with respect to their structures. (10 refs.)

109245 The behaviour of a metallic dispersion under microgravity conditions. G.H.Otto (DFVLR, Inst. for Space Simulation, Koln-Porz, Germany).
Proceedings of the 4th European Symposium on Materials Sciences under Microgravity (ESA SP-191), Madrid, Spain, 5-8 April 1983 (Paris, France: ESA 1983), p.63-9
The metallic system gallium-mercury with a liquid state miscibility gap is used to perform a dispersion experiment under microgravity conditions. Unlike previous experiments the sample will not be solidified but cooled into the miscibility gap only. The resulting liquid/liquid dispersion and its development upon further cooling will be recorded by X-ray transmission photography. Three different cooling rates will be executed with the same sample which is designed to be recyclical. The influence of time and gradient dependent effects, like homogenization, droplet growth, Marangoni convection, or Stokes' sedimentation on the stability of the dispersion will be considered. The experiment is scheduled to be reflown on STS-7. (15 refs.)

109246 Low-gravity experiments on liquid phase miscibility gap (LPMG) alloys—materials experiments assembly (MEA). S.H.Gelles (S.H. Gelles Associates, Columbus, OH, USA), A.J.Markworth, C.E.Mobley.
Proceedings of the 4th European Symposium on Materials Sciences under Microgravity (ESA SP-191), Madrid, Spain, 5-8 April 1983 (Paris, France: ESA 1983), p.307-12
Four experiments planned for performance on future Space Shuttle flights are described. They are to be performed in the Materials Experiments Assembly (MEA) and are concerned with understanding the evolution of microstructure in liquid phase miscibility gap (LPMG) alloys especially the reasons for the occurrence of massive separation in the SPAR II and SPAR V experiments on Al-In Alloys. The experiments are as follows: 1. Gradient cool experiment on Al-90 wt.% In. 2. Isothermal experiment on Te-Tl alloys. 3. Plunger experiment on Al-90 wt.% In alloy in alumina. 4. Plunger experiment on Al-40 wt.% In alloy in SiC coated graphite. (13 refs.)

109247 Interactions of LiBr with calcite and calcium oxide powders. D.Deruto, G.Belleri, L.Barco (Istituto di Chimica, Facolta di Ingegneria, Univ. di Genova, Genova, Italy), V.Longo.
Ceram. Int. (Italy), vol.9, no.2, p.53-8 (1983).
The interactions of LiBr with calcite and calcium oxide powders have been studied with and without the calcite decomposition reaction, using DTA and TG analysis plus SEM and RX observations. Interactions in the LiBR-$CaCO_3$ system show two possible phase transformations at the temperature of 748K and 786K. The second one is due to the formation of an eutectic liquid phase in the LiBr-rich region. The rate of decomposition of calcite powders was measured in dry nitrogen and in a high partial pressure of CO_2 with and without LiBr. The addition of LiBr causes the decomposition reaction to occur at a lower temperature. The LiBr changes the mechanism of the reaction. The decomposition process occurs through a liquid-phase path given by the eutectic of LiBr-$CaCO_3$. The total rate of reaction as well as the temperature dependence are related to the liquid phase. The $CaCO_3$ powders obtained have a very dense structure with a high degree of crystallization. Probably the LiBr-CaO eutectic provides a solution path for CaO recrystallization. The effectiveness of salt addition in lowering the decomposition temperature of carbonates seems promising in saving energy, as well as in promoting changes in morphology of important commercial oxide powders. (13 refs.)

109248 Formation of solid solutions in vacuum condensed Al_2O_3-ZrO_2 systems. G.I.Batalin, V.D.Kushkov, O.V.Kachur, O.M.Zaslavs'kii, I.S.Kozlov.
Dopov. Akad. Nauk UkRSR. Ser. A (USSR), no.5, p.78-81 (1983). In Ukrainian.
X-ray phase analysis and X-ray microanalysis methods were used to study the Al_2O_3-ZrO_2 vacuum condensates obtained by electron-beam evaporation and vacuum condensation. Data are presented on the phase composition of vacuum condensates in a wide range of component concentrations and condensation temperatures. It is shown that the composition of solid zirconium oxide-base solutions formed in vacuum Al_2O_3-ZrO_2 condensates does not correspond to the component content in the samples. (9 refs.)

109249 $CuGaS_{2x}Se_{2(1-x)}$ solid solutions. I.V.Bodnar', A.P.Bologa (Inst. of Solid-State & Semiconductor Phys., Acad. of Sci., Belorussian SSR).
Inorg. Mater. (USA), vol.18, no.8, p.1060-4 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1257-61 (Aug. 1982).
As a result of the investigations carried out, the phase diagram of the system $CuGaS_2$-$CuGaSe_2$ has been constructed for the first time. For the system, the solidus and liquidus lines were calculated in the approximations of the theory of ideal and regular solutions. Monocrystals of the ternary compounds $CuGaS_2$, $CuGaSe_2$, and solid solutions $CuGaS_{2x}Se_{2(1-x)}$ were grown by the chemical transport reaction method and their dislocation structure studied. (19 refs.)

109250 Phase diagram of the PbSe-CdTe system. S.D.Raevskii, K.R.Zbigli, G.F.Kazak, M.D.Prunich (All-Union Sci.-Res., Structural-Engng. & Technol. Inst. of Current Sources, USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1068-71 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1267-70 (Aug. 1982).
The phase diagram of the PbSe-CdTe system has been studied by differential thermal, X-ray diffraction, and metallographic analyses. The system is not quasi-binary. The width of the region of solid solutions on the PbSe side is ~27.5 mole % CdTe at 880°C, and on the CdTe side it is less than 2.5 mole % PbSe at 850°C. The unit cell parameters of the solid solutions on the PbSe side vary with the composition as $\alpha=6.121-0.081x$ Å. In the $PbSe+CdTe \rightleftharpoons PbTe+CdSe$ system the equilibrium is shifted to the right. (11 refs.)

109251 Phase equilibria in the binary systems $Pb(PO_3)_2$-$PbMoO_4(PbWO_4)$ and $Pb_2P_2O_7$-$PbMoO_4(PbWO_4)$. G.A.Bukhalova, I.V.Mardirosova, N.P.Ocheret (Rostov Structural Engng. Inst., Rostov, USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1168-71 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1376-9 (Aug. 1982).
Phase equilibria in systems composed of lead phosphates and molybdates (tungstates) were studied by the methods of differential thermal, visual polythermal, and X-ray phase analysis. The phase diagrams of the systems $Pb(PO_3)_2$-$PbMoO_4$, $Pb(PO_3)_2$-$PbWO_4$, $Pb_2P_2O_7$-$PbMoO_4$ and $Pb_2P_2O_7$-$PbWO_4$ were found to be of the eutectic type; in two of the latter the formation of limited solid solutions based on the starting compounds was observed. (7 refs.)

109252 Interaction of phosphorus with zirconium and cobalt. Ya.F.Lomintskaya, Yu.B.Kuz'ma (I. Franko L'vov State Univ., L'vov, Ukrainian SSR).
Inorg. Mater. (USA), vol.18, no.8, p.1176-7 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1385-6 (Aug. 1982).
In the system Zr-Co-P, the compounds ZrCoP (structure of the TiNiSi type, $\alpha=0.6332$, $b=0.3698$, $c=0.7160$ nm), $Zr_2Co_4P_3$ ($Hf_2Co_4P_3$, $\alpha=1.210$, $c=0.3662$ nm), and $Zr_2Co_{12}P_7$ ($Zr_2Fe_{12}P_7$, $\alpha=0.8950$, $c=0.3557$ nm) and a solid solution of phosphorus in Zr_2Co, the boundary of which is described by the formula Zr_4CoP, are known. A systematic study of the interaction of phosphorus with zirconium and cobalt is presented. (12 refs.)

109253 Phase diagram of the systems $Cu_{2-x}S$-ZnS and $Cu_{2-x}Se$-ZnSe. I.B.Mizetskaya, G.S.Oleinik, L.N.Trishchuk (Inst. of Semiconductors, Acad. of Sci., Ukrainian SSR).
Inorg. Mater. (USA), vol.18, no.11, p.1538-40 (Nov. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.11, p.1792-4 (Nov. 1982).
The phase diagrams of the systems $Cu_{2-x}S$-ZnS and $Cu_{2-x}Se$-ZnSe have been investigated by the methods of DTA and microstructural analysis. It has been ascertained that the systems are of the peritectic type with restricted solubility in the solid state. The limits of existence of solid solutions based on the copper chalcogenides are 42 and 55 mole % of the zinc chalcogenides at 1185 and 1142°C, respectively, for the former and the latter system. Copper sulfoselenides can be used as solvents for obtaining single crystals of zinc sulfoselenides from solutions in a melt. (12 refs.)

109254 Phase equilibria in the Ag_2Se-ZnSe and Ag_2Se-CdSe systems. L.I.Trishchuk, G.S.Oleinik, I.B.Mizetskaya (Inst. of Semiconductors, Acad. of Sci., Ukrainian SSR).
Inorg. Mater. (USA), vol.18, no.11, p.1540-2 (Nov. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.11, p.1795-7 (Nov. 1982).
The phase equilibria in the Ag_2Se-ZnSe and Ag_2Se-CdSe systems have been investigated by the methods of differential thermal and microstructural analysis. It has been established that the phase diagram of the Ag_2Se-ZnSe system is of the eutectic type (a composition of 13.5 mole % ZnSe and a temperature of 850°C correspond to the eutectic point). The limiting solubility of zinc selenide in silver selenide at 850°C is 12 mole %. The phase diagram of the Ag_2Se-CdSe system is of the peritectic type (a composition of 62 mole % CdSe and a temperature of 970°C correspond to the peritectic point). Solid solutions based on Ag_2Se exist over the concentration range 0-68 mole % CdSe. The solubility in the solid state in both systems sharply decreases with falling temperature. The compound Ag_2Se can be used as a solvent in the cultivation of ZnSe and CdSe single crystals from solution in melt. (4 refs.)

109255 Phase equilibria of the Bi-Se-I system in the BiSeI-Bi and BiSeI-BiI sections. G.I.Chervenyuk, P.F.Babyuk, D.P.Belotskii, T.G.Chervenyuk (Chernovtsy State Univ., Chernovtsy, USSR).
Inorg. Mater. (USA), vol.18, no.11, p.1569-72 (Nov. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.11, p.1827-9 (Nov. 1982).
The phase diagrams of the BiSeI-Bi and BiSeI-BiI sections of the Bi-Se-I ternary system have been constructed. It has been shown that the BiSeI-Bi section is quasi-binary and that the BiSeI-BiI section is nonquasi-binary with phase separation on the BiI side extending to 17 mole % BiSeI. An increase in the selenium content in the alloys results in reduction of the separation of phases. (9 refs.)

109256 Reactions in the Cu_2Se-In_2Se_3-Se ternary system. T.I.Koneshova, A.A.Babitsyna, V.T.Kalinnikov (N.S. Kurnakov Inst. of General & Inorganic Chem., Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.9, p.1267-70 (Sept. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.9, p.1483-6 (Sept. 1982). [received: Sept. 1983]
As a result of the investigation of interaction in the Cu_2Se-In_2Se_3 binary system and in the Cu_2Se-In_2Se_3-Se ternary system a projection of the liquidus surface was constructed from the CuSe-In_2Se_3 and $CuInSe_2$-Se sections. It was confirmed that solid solutions based on the ternary compounds $CuInSe_2$ and $CuIn_3Se_5$ exist in this system. (12 refs.)

109257 The Tl_2Se-As system. V.V.Kirilenko, V.A.Samokhov, N.G.Velikova, R.N.Shchelokov, A.V.Medvedev (N.S. Kurnakov Inst. of Central & Inorganic Chem., Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.9, p.1270-2 (Sept. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.9, p.1487-8 (Sept. 1982). [received: Sept. 1983]
By means of differential thermal, X-ray phase, and microstructural analyses and microhardness measurements, the authors have investigated the phase diagram of the Tl_2Se-As cross section of the Tl-As-Se system. The cross section is quasi-binary. The chemical compound Tl_4AsSe_2, melting congruently at 658K, is found. The phase diagram is also characterized by the presence of a eutectic between Tl_4AsSe_2 and As and a continuous series of solid solutions between Tl_4AsSe_2 and Tl_2Se. (5 refs.)

109258 The $TlAsSe_2$-Tl system. V.V.Kirilenko, V.A.Samokhov, N.G.Velikova, R.N.Shchelokov, A.V.Medvedev (N.S. Kurnakov Inst. of General & Inorganic Chem., Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.9, p.1272-6 (Sept. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.9, p.1489-93 (Sept. 1982). [received: Sept. 1983]
By DTA and XPA methods, together with an investigation of the microstructure and measurements of the microhardness, the authors have studied the phase diagram of the $TlAsSe_2$-Tl system, which is quasi-binary. In the system they find three chemical compounds: Tl_4AsSe_2, which melts congruently at 658K; Tl_2AsSe_2, which melts congruently at 563K; and $Tl_6As_5Se_{10}$, which melts congruently at 491K. There are regions of homogeneity based on Tl_4AsSe_2 and Tl_2AsSe_2. The phase diagram is also characterized by the existence of a region of phase separation in the liquid state. The authors have determined the glass points of the amorphous alloys and have calculated Tg by the method adopted in the chemistry of high-molecular compounds. A structural model is proposed for the glass-forming compounds Tl_2AsSe_2 and $Tl_6As_5Se_{10}$. (8 refs.)

109259 The Tl_4AsSe_2-AsSe system. V.V.Kirilenko, V.A.Samokhov, N.G.Velikova, R.N.Shchelokov, A.V.Medvedev (N.S. Kurnakov Inst. of General & Inorganic Chem., Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.9, p.1277-81 (Sept. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.9, p.1494-9 (Sept. 1982). [received: Sept. 1983]
By means of DTA, XPA, microstructural investigations, and microhardness measurements the authors have investigated the phase diagram of the cross section AsSe-Tl_4AsSe_2. They show that this cross section is quasi-binary and is characterized by the presence of two new ternary chemical compounds, $Tl_8As_5Se_7$ and $Tl_8As_{13}Se_{15}$, formed by peritectic reactions at 565 and 513K, respectively. The interaction between $Tl_8As_5Se_7$ and $Tl_8As_{13}Se_{15}$ is eutectic, the composition of the eutectic is 70 mole% AsSe, and its melting point is 500K. Regions of homogeneity based on Tl_4AsSe_2 and $Tl_8As_5Se_7$ are found. The authors have made a triangulation of the ternary system Tl-As-Se into nine partial subsystems. They have determined the glass points of the amorphous alloys. To these they have applied the method of calculation of T_g(K) adopted in the chemistry of high-molecular substances. They show that this method can serve for a preliminary estimate of the character of the chemical interaction in glass-forming chalcogenide systems. (15 refs.)

109260 Crystal chemistry and phase relations in the system Li_2O-Fe_2O_3-TiO_2. Yu-Chyi Yau, J.M.Hughes (Dept. of Geology, Miami Univ., Oxford, OH, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.479-81 (July 1983).
Above 755°C, compounds along the spinel join $LiFe_5O_8$-$Li_4Ti_5O_{12}$ form a complete solid solution and below that temperature a two-phase region separates the ordered $LiFe_5O_8$ and the disordered spinel phase. At 800° and 900°C, cubic $LiFeO_2$ (*ss*) and monoclinic Li_2TiO_3 (*ss*) exist on the monoxide join $LiFeO_2$-Li_2TiO_3. The distributions of cations in both the spinel and monoxide structures were calculated as a function of equilibrium temperature and composition. Subsolidus equilibria in the system Li_2O-Fe_2O_3-TiO_2 at 800° and 900°C were determined for compositions containing ≤ 50 mol% Li_2O. (18 refs.)

109261 Revised phase diagram of the system ZrO_2-CeO_2 below 1400°C. E.Tani, M.Yoshimura, S.Somiya (Dept. of Materials Sci. & Engng., Tokyo Inst. of Technol., Yokohama, Japan).
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.506-10 (July 1983).
The phase diagram of the system ZrO_2-CeO_2 was reinvestigated using hydrothermal techniques. Cubic, tetragonal, and monoclinic solid solutions are present in this system. The tetragonal solid solution decomposes to monoclinic and cubic solid solutions by a eutectoid reaction at 1050° ± 50°C. The solubility limits of the tetragonal and cubic solid solutions are about 18 and 70 mol% CeO_2, respectively, at 1400°C, and about 16 and 80 mol% CeO_2, respectively, at 1200°C. Solubility limits of the monoclinic and cubic solid solutions are about 1.5 and 88 mol% CeO_2 at 1000°C, and 1.5 and 98 mol% CeO_2 at 800°C, respectively. The compound $Ce_2Zr_3O_{10}$ is not found in this system. (19 refs.)

109262 Solid solubility of GeO_2 in SnO_2. A.Watanabe, T.Kikuchi, M.Tsutsumi, S.Takenouchi, K.Uchida (Nat. Inst. for Res. in Inorganic Materials, Ibaraki, Japan).
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.C104-5 (July 1983).
Subsolidus equilibrium relations were reexamined in the SnO_2-rich portion of the system GeO_2-SnO_2 (60 to 98 mol% SnO_2). A limited solid solution based on SnO_2 was confirmed; ≈ 4 mol% GeO_2 dissolved in SnO_2 at 1250°C, and glass was formed on quenching over the compositional range above 4 mol% GeO_2. Phase relations in the system are discussed with reference to the polymorphism of GeO_2 and its glass-forming ability, and a possible phase diagram is given. (9 refs.)

109263 Thermochemistry of Na_2O-WO_3 system at 1065 to 1239K. R.Y.Lin (GTE Labs., Waltham, MA, USA), J.F.Elliott.
Metall. Trans. A (USA), vol.14A, no.8, p.1713-20 (Aug. 1983).
Physico-chemical properties of the Na_2O-WO_3 binary oxide system have been studied. The activity of Na_2O in Na_2O-WO_3 melts has been determined for temperatures from 1065 to 1239K and for the composition range of N_w (mole fraction of WO_3) from 0.5 to 0.84. It has been calculated that at 1200K and for $0.52<N_w<0.08$, the relative partial molar free energy of Na_2O is $G_N{}^M=95.10-347.2N_w$;(kJ/nole). For temperatures between 1065K and 1213K and compositions between $N_w=0.5$ and $N_w=0.8$, the relative partial molar enthralpy was found to be $H_N{}^M=-709.8+262.58/N_w$; (kJ/mole). The free energies of the compounds in this system were also estimated. (16 refs.)

109264 A molybdenum sulfur binary phase diagram. W.B.Johnson (Dept. of Metall. Engng., Ohio State Univ., Columbus, OH, USA), W.S.Hong, D.W.Readey.
Scr. Metall. (USA), vol.17, no.7, p.919-22 (July 1983).
An Mo-S binary phase diagram is proposed for compositions below 66.67 atom per cent sulfur based upon the evaluation of previously published results. (22 refs.)

109265 The occurence, effect, and control of twinned columnar growth in aluminum alloys. D.A.Granger, J.Liu (Alcoa Tech. Center, Alcoa Center, PA, USA).
J. Met. (USA), vol.35, no.6, p.54-9 (June 1983).
The cast structure known as twinned columnar growth (TCG) is characterized by large colonies of twinned columnar grains which are most likely to occur when conditions are unfavorable for the nucleation and growth of new grains during solidification. Casting methods and alloy systems that are most susceptible to TCG formation are identified, and the effects of the structure on mechanical properties are quantified for sections where remnants of the defect exist after fabrication processing. Observed loss in ductility is associated with planes of weakness which can be traced back to TCG structure in the ingot. Methods available to control ingot grain structure, and arrest the formation of TCG, through an understanding of the solidification process are discussed. (15 refs.)

109266 Impinging melt flow and metallic ribbon formation in the single-roll rapid solidification process. K.Miyazawa, T.Choh (Dept. of Metall. Engng., Nagoya Univ., Nagoya, Japan).
J. Jpn. Inst. Met. (Japan), vol.47, no.8, p.717-23 (Aug. 1983). In Japanese.
Metallic ribbon formation from a cylindrical melt jet in the single-roll rapid solidification process has been investigated to explore the dependence of ribbon geometry on the impinging melt flow on a rotating roll. Results of the experiment using round orifice nozzles and Pb-Sb eutectic alloy show that the spreading of melt on the roll increases with decreasing roll surface velocity and with increasing melt flow rate and melt temperature in the nozzle. Effects of the key process parameters on the ribbon geometry are discussed through considering characteristics of the flow. (28 refs.)

109267 Unidirectional solidification behaviors at high cooling rates in Al-Fe-Mn ternary eutectic alloys. Kang Yul Lee, Kwang Chae Choe, Hyun-Kee Cho.
J. Korean Inst. Met., vol.21, no.5, p.451-8 (May 1983). In Korean.
Unidirectional solidification experiments were conducted on Al-Fe-Mn ternary eutectic alloys at a temperature gradient 80°C/cm in the range of solidification rates of 1-38 mm/min in order to investigate the solidification and mechanical behavior. It has been established that the morphology of the composite structure changed from the plate type into the square pillar or rod type as the solidification rate increased. The chemical composition of fibers at low solidification rates was $Fe(Mn)Al_3$, and that at high solidification rates was $(FeMn)Al_6$. The faster solidification rate produced the higher ultimate tensile strength. But the ultimate tensile strength decreased by misalignment of fibers at very high solidification rates. The ultimate tensile strength of unidirectionally solidified and aged specimens have the same value as that of only unidirectionally solidified specimens. (12 refs.)

109268 A study on the modification of eutectic Al-Si alloys by Sr in permanent mold casting. Choon Sik Kang (Dept. of Metall. Engng., Coll. of Engng., Seoul Nat. Univ., Seoul, Korea), Seung Ho Ahn.
J. Korean Inst. Met., vol.21, no.5, p.500-6 (May 1983). In Korean.
Al-Si alloys have been modified by Na. However, because of the fading tendency of Na, modification of Al-Si alloys by Sr is currently being researched. Besides Na addition, a high cooling rate also results in modification. An experiment was performed to study the modification of Al-Si alloys by Sr in permanent mold casting and was focused on Sr content for complete modification, improvement of mechanical properties, thermal analysis and shrinkage. At 0.3% Sr, when the mold is preheated to 200°C, complete modification was accomplished and mechanical properties were considerably improved. The thermal analysis curve and shrinkage tendency may be used for determining the degree of modification in the permament mold casting. (22 refs.)

109269 Structural formation of high-speed steels during crystallization. P.F.Nizhnikovskaya, E.P.Kalinushkin, L.M.Snagovskii, G.F.Demchenko.
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.777-84 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.23-30 (Nov. 1982).
It is concluded that the $L+\delta\rightarrow\gamma$ peritectic transformation in tungsten-molybdenum high-speed steels goes to completion prior to the start of the eutectic reaction $(L\rightarrow\gamma+K)$, which may precede segregation of austenite from the liquid (with a high carbon content). In this case, the eutectic is crystallized on the base of the metastable M_2C carbide. Conditions for the formation of thermodynamically more stable MC and M_6C carbides are created during slow cooling characteristic for the central zones and upper horizons of an ingot. Eutectics based on these carbides begin to crystallize at comparatively high temperatures, when the peritectic transformation has yet to go to completion. In a certain temperature interval, these transformations occur simultaneously; in this case, they can be suppressed by the eutectic crystallization owing to the characteristic features of the peritectic transformation. As a result, δ-ferrite (the products of its decomposition) is present in the steel. (17 refs.)

109270 Structure and properties of alloys of the Al-Mn system quenched from the liquid state. V.M.Fedorov, T.I.Lebedeva (All-Union Inst. of Light Alloys, VILS, Moscow, USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.808-10 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.46-8 (Nov. 1982).
It was found that an increase in cooling rate during granule crystallization for the alloy system Al-Mn to 10^5 deg/sec makes it possible to move the boundary for anomalous supersaturation of manganese solid solution in aluminum in the direction of greater manganese concentration. The possibility of further increasing solid solution supersaturation provides an additional strengthening effect during its decomposition and an increase in strength properties for semifinished products made at room and elevated temperature. However, the maximum strengthening during decomposition moves in the direction of lower heating temperature, and solid solution decomposition proceeds more rapidly. Therefore, in order to obtain the maximum properties for semifinished products granule deformation should be carried out at the lowest possible temperature. (6 refs.)

109271 On the difference between 'baykovite' and finely dispersed ledeburite. A.A.Zhukov, A.N.Kokora, R.L.Snezhnoy.
Russ. Metall. (GB), no.1, p.78-81 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.91-4 (1982).
Baykovite is shown to a be a new structural component in iron carbon alloys, possessing a phase composition the same as ledeburite, but differing from it in its creation. Baykovite is formed from iron supersaturated cementite during the cooling process by the stratiation of its lattice predominantly along the (001) planes into plates of 'stoichiometric' cementite Fe_3C and austenite interlayers. The direction of baykovite banding is independent of heat outflow direction, whereas the structure of ledeburite is determined primarily by this factor. (10 refs.)

109272 Features of formation and breakdown of microcrystalline and amorphous phases in splat-cooled cerium-silver alloys. A.A.Yakunin, A.B.Lysenko.
Russ. Metall. (GB), no.1, p.125-7 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.144-9 (1982).
The quenching of liquid Ce-Ag alloys in various concentration ranges made it possible to synthesise X-ray amorphous phases of greatly differing nature, both amorphous and microcrystalline. The splat cooled alloys whose composition is similar to that of the low-temperature eutectic (10-35 Ag) had a truly amorphous structure. The X-ray amorphous phase formed in the quenching of the Ce+(5-6)%Ag alloys was a conglomerate of the microcrystals of α-Ce with a high concentration of stacking faults and of the BCC_m phase with around 8%Ag. (5 refs.)

109273 Form of growth of primary phases and micromorphology of controlled eutectics. D.G.Borshchevskaya, T.Ya.Evina.
Russ. Metall. (GB), no.2, p.172-5 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.189-93 (1982).
The eutectic alloys of various system combination with silver, Ag-Cu, Ag-Bi, Ag-Ge and Ag-Pb were used for the investigation. Silver crystals in all the eutectics have both rounded and flat faced forms of growth. In the Ag-Bi and Ag-Pb alloys, with a decreasing concentration and increasing degree of supercooling of the solution, a change in the mechanism of growth of silver crystals is observed (from layered to normal or vice versa). The morphology of directionally crystallised binary Ag-Cu, Ag-Si, Ag-Bi, Ag-Ge and Ag-Pb eutectics is determined by forms of growth and some kinetic features of the development of interlinked phases. (10 refs.)

109274 Investigation of the crystallisation of alloys in systems containing peritectic transformations. V.I.Psarev, V.G.Kiriy, A.V.Kuznetsov, I.V.Psareva, A.L.Ivanova.
Russ. Metall. (GB), no.2, p.175-82 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.193-200 (1982).
An investigation was undertaken in order to establish relationships in stable and metastable crystallisation of alloys in systems with peritectic transformations (Sb-Zn; Al-Mn, Sn-Au, Ge-Te and In-Te) at cooling velocities of the melts from 50 deg/h to 10^5 deg/sec. On the basis of established relationships, some additions were introduced into the phase diagrams of the systems which take some features of the metastable crystallisation of alloys into consideration. A retardation in restructuring the internal structure of melts on passing through the peritectic horizontal lines, shown on the state diagram of the Al-Mn system, can be one of the main causes of the two sided shifts of the peritectic transformations during heating and cooling of the melts. Intermediate compounds $AuSn_2$ and $AuSn_4$ of the Sn-Au system melt monocongruently, which prohibits the possibility of prolonging the liquidus line into the subcritical zone. Some corrections in the construction of the state diagram of the Sn-Au system were introduced. (14 refs.)

109275 Regularities in the precipitation of W-Re alloys from a mixture of their hexafluorides with hydrogen. Lakhotkin Yu.V., A.I.Krasovskiy.
Russ. Metall. (GB), no.3, p.25-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.3, p.27-31 (1982).
Investigation of the kinetics of precipitation of W-Re alloys from a mixture of their hexafluorides with hydrogen indicated that between 450-800°C the precipitation rate of rhenium in the alloys is controlled by the diffusion of rhenium hexafluoride to the substrate. It was established that on a simultaneous precipitation of tungsten and rhenium, the latter considerably increases the solidification rate of tungsten. The relative increase in the solidification rate of tungsten on its co-precipitation with rhenium increases with a decreasing substrate temperature, an increasing rhenium content in the alloy, and depends on the phase composition of the alloy. Investigation of the morphology of the surface of growth of the alloy indicated that separating the phases of the structural type A-15 in the matrix of the solid solution of the alloy containing 9% rhenium changes the acceleration mechanism of solidification tungsten. The mechanism of the kinetic acceleration of tungsten solidification during its co-precipitation with rhenium was proposed. (7 refs.)

109276 Ostwald ripening and solidification behaviour of near-monotectic Zn-Pb alloys. A.Kneissl, P.Pfefferkorn (Montanuniv. Leoben, Leoben, Austria), H.Fischmeister.
Proceedings of the 4th European Symposium on Materials Sciences under Microgravity (ESA SP-191), Madrid, Spain, 5-8 April 1983 (Paris, France: ESA 1983), p.55-61
Liquid hyper-monotectic Zn-Pb alloys are immiscible within a certain temperature range. The large difference in density between lead and zinc leads to rapid gravity segregation. The objective of the Spacelab experiment 1 ES 313 is to maintain a suspension of lead droplets in a zinc-rich liquid matrix and to study the rate of Ostwald ripening without disturbance by segregation. In preparation of the Spacelab experiment, this paper deals with the solidification behaviour and Ostwald ripening of near-monotectic Zn-Pb alloys under terrestrial conditions. It is shown that the experimental conditions during the Spacelab flight should allow measurements of coarsening by Ostwald ripening and should grant the solidification of the suspension without disturbance by the motion of the solidification front. 81.30H Constant-composition solid-solid phase transformations: polymorphic, massive, and order-disorder

(see also 64.70K Solid-solid transitions)

109277 The isothermal δ-γ transformation of ferritic-austenitic iron-chromium-nickel alloys. R.Mundt, H.Hoffmeister (Lab. fur Werkstoffkunde und Schweisstech., Hochschule der Bundeswehr Hamburg, Hamburg, Germany).
Arch. Eisenhuettenwes. (Germany), vol.54, no.7, p.291-4 (July 1983).
By quenching from ferritizing temperatures of 1350 and 1250°C, the isothermal δ-γ transformation of two iron-chromium-nickel alloys with 26.0% Cr, 6.9% Ni and 30.0% Cr, 7.05% Ni respectively, at temperatures between 700 and 1200°C is studied. Three different transformation stages are revealed indicating grain boundary diffusion controlled growth in the first and last stage while volume diffusion seems to act at least partially in the second stage. Isothermal TTT diagrams are established and activation energies calculated. (19 refs.)

109278 A continuum approach to transformation kinetics of metals. K.Tanaka (Dept. of Aeronautical Engng., Univ. of Osaka Prefecture, Osaka, Japan), R.Iwasaki, S.Nagaki.
Bull. Univ. Osaka Prefect. Ser. A (Japan), vol.31, no.1, p.1-9 (1982).
A continuum model for the solid-solid transformation kinetics of diffusion type is proposed. The theoretical procedure to figure the continuous cooling transformation diagram (C-C-T diagram) and the time-temperature-transformation diagram (T-T-T diagram) is discussed. Some numerical results are given for the austenite-pearlite transformation of steels. (16 refs.)

109279 Inhibition mechanism of the anatase-rutile phase transformation by rare earth oxides. S.Hishita (Dept. of Industrial Chem., Univ. of Tokyo, Tokyo, Japan), I.Mutoh, K.Koumoto, H.Yanagida.
Ceram. Int. (Italy), vol.9, no.2, p.61-7 (1983).
The effect of rare earth oxide additions on the anatase-rutile transformation in doped TiO_2 was investigated. Y_2O_3, La_2O_3, CeO_2, Nd_2O_3, Sm_2O_3, Gd_2O_3, Tb_4O_7, Ho_2O_3, Dy_2O_3, Er_2O_3, Tm_2O_3 and Yb_2O_3, were found to suppress the transformation. The transformation process occurs in three stages. In the first stage, rare earth metal ions dissolve into interstitial sites in anatase. The resulting decrease in oxygen vacancies caused by the solid solution suppresses the nucleation of the transformation. In the second stage, the activation energy of the transformation was found to be 124±3 Kcal/mol and 138±4 Kcal/mol for pure anatase and anatase with 1 mol% Dy_2O_3, respectively. The transformation mechanism of this stage is not necessarily affected by additives. The final stage is affected by the amount of rare earth oxide-titania compound phase. (22 refs.)

109280 Influence of plastic deformation on phase transitions during ageing of titanium alloy VTZ-1. M.V.Mal'tsev, N.I.Kashnikov (A.A. Zhdanov Polytech. Inst., Gorki, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.110-14 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of phase transitions occurring during ageing of alloy VTZ-1 quenched to give a structure containing a mechanically unstable β-phase deformed to different extent by compression. Plastic deformation produced α''-martensite with a preferential orientation. A unit cell of the β-phase, which did not undergo the transition, was distorted during deformation becoming tetragonal but retaining its initial volume. Such distortions were oriented relative to the deformation axis. Deformation after quenching accelerated stratification of the β-phase and transition of the depleted β-phase to the α''-modification. (3 refs.) *A.T.*

109281 Investigation of compounds of the type $(A_{0.5}^{2+}Bi_{0.5})(B_{0.5}^{2+}Nb_{0.5})O_3$. L.G.Kosyachenko, V.V.Kochetkov, A.G.Belous, V.V.Bogatko, Yu.N.Venevtsev (L.Ya. Karpov Sci.-Res. Phys. Chem. Inst., Moscow, USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1146-51 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1352-8 (Aug. 1982).
Phase transitions were observed in the perovskites $(Sr_{0.5}Bi_{0.5})(Mg_{0.5}Nb_{0.5})O_3$, $(Sr_{0.5}Bi_{0.5})(Zn_{0.5}Nb_{0.5})O_3$, $(Ba_{0.5}Bi_{0.5})(Mg_{0.5}Nb_{0.5})O_3$, and $(Ba_{0.5}Bi_{0.5})(Zn_{0.5}Nb_{0.5})O_3$. A series of data was presented which was evidence for the presence of a spontaneously polarized state in the indicated compounds. (12 refs.)

109282 Transformation behaviour of laser processed Fe-5%Cr, Fe-5%Ni and Fe-6%Cr-2%Ni alloys. P.A.Molian, W.E.Wood (Dept. of Materials Sci., Oregon Graduate Center, Beaverton, OR, USA).
J. Mater. Sci. (GB), vol.18, no.9, p.2555-62 (Sept. 1983).
The effects of rapid cooling of the order of 10^4°C sec^{-1}, achieved through the laser surface alloying process, on the transformation behaviour of Fe-5%Cr, Fe-5%Ni and Fe-6%Cr-2%Ni alloys have been investigated. The solidification structures and microstructures were characterized by optical and transmission electron microscopy. The significant findings are that Fe-5%Cr alloy undergoes a massive transformation to ferrite while Fe-5%Ni and Fe-6%Cr-2% Ni alloys undergo a transformation to a structure consisting of both ferrite and martensite. The substructures of ferrite and martensite were observed to contain essentially dislocations. These alloys also exhibited two carbide precipitations, namely epsilon carbide and cementite. Solidification studies revealed that cellular solidification structures were present in 5%Ni and 6%Cr-2%Ni alloys with a cell spacing of 3 μm but no solidification structures were observed in 5%Cr alloy. The influence of nature of solute and cooling rate on solidification behaviour, transformation mode and morphology of structures have been discussed. (25 refs.)

109283 Transformation structures and strengthening mechanisms of laser processes Fe-Cr alloys. P.A.Molian, W.E.Wood (Dept. of Materials Sci. & Engng., Oregon Graduate Center, Beaverton, OR, USA).
J. Mater. Sci. (GB), vol.18, no.9, p.2563-71 (Sept. 1983).
The microstructures and microhardness of laser processed Fe-Cr surface alloys were investigated as functions of composition (5 to 50 wt.% Cr) and melt penetration depth (100 to 1500 μm). The transformation structures were characterized by optical metallography and thin foil transmission electron microscopy. The microstructures were ferritic irrespective of compositions and melt depths. The alloys containing chromium up to 12% (within the γ-phase field) exhibited a massive ferritic morphology while the alloys containing chromium more than 12% (beyond the γ-phase field) showed an equiaxed ferritic morphology. Transmission electron microscopy studies revealed that the substructure of ferrite consisted of dislocations, the dislocation density increased with increased chromium content. Melt depth, unlike composition, did not have significant effect on the morphology and substructure of ferrite grains. Small amounts of ε-carbide and M_3C carbide phases were observed in these alloys. Both the carbides were found to decrease with an increase in the chromium of the fusion zone. (17 refs.)

109284 Austenitization of steel during chip formation. J.L.Hau-Bracamonte, M.L.H.Wise (Dept. of Metallurgy & Materials, Univ. of Birmingham, Birmingham, England).
Metall. Trans. A (USA), vol.14A, no.8, p.1743-5 (Aug. 1983).
The flow-zone structure of 0.4% C steel chips produced by turning at −196°C has been studied by a combination of microhardness measurements and optical, scanning, and tranmission electron microscopy. This has shown conclusively that pearlite can transform to austenite during cutting despite the extremely high heating rate (e.g. 6×10^5°Cs^{-1}) and short time (e.g. 1.5 to 5.5 ms) at temperature during which transformation can occur (e.g. ≥750°C). (15 refs.)

109285 On the possibility of the transfer of iron on a quasi-liquid state during polymorphic transformation in hydrogen [dynamic superplasticity]. V.I.Shapovalov, V.Yu.Karpov.
Russ. Metall. (GB), no.1, p.53-5 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.59-63 (1982).
A strong influence of hydrogen on the dynamic superplasticity of Fe in a wide range of pressures was detected. It consisted of an anomalous fall in yield point transforming the metal into a quasiliquid state. The phenomenon was observed of a directional spontaneous change in specimen shape when thermocycling in the temperature gradient zone in the presence of hydrogen. (6 refs.)

109286 On the phase transformations in samarium at temperatures 200-600°C. A.A.Spasskaya, V.V.Shishkov.
Russ. Metall. (GB), no.1, p.128-30 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.150-3 (1982).
The phase transformation in Sm in the temperature range 200 to 400°C is associated with the process of dissolution of the oxide phase. Transformation close to 600°C occurs at a constant temperature and is an allotropic transformation. The reason for the appearance of the transformation is discussed. (10 refs.)

109287 Process occurring in supercooled austenite before pearlitic transformation. A.V.Kulemin, S.Z.Nekrasova, R.I.Entin, V.A.Meshalkin.
Russ. Metall. (GB), no.3, p.63-5 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.3, p.68-70 (1982).
Processes preceding pearlitic transformation in variously alloyed steels 50G4 (0.5% C, 4.3% Mn), 50Kh3 (0.5% C, 3.1% Cr), and 45Kh2N4M (0.45% C, 2% Cr, 4% Ni, 0.3% Mo) were investigated using an ultrasonic method. The measurements were carried out in the lower branch of the pearlitic region, at which temperatures the kinetics of transformation is determined mainly by the diffusion mobility of atoms. (6 refs.)

109288 Influence of rapid cooling on the polymorphic transformations in pure metals. D.A.Mirzayev, V.G.Ul'yanov.
Russ. Metall. (GB), no.3, p.90-4 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.3, p.103-9 (1982).
A stepwise dependence of the temperature of the beginning of the polymorphic transformation on the cooling velocity was found in the fifth group of polymorphic metals (titanium, zirconium, iron, cobalt). In the case of titanium, zirconium and cobalt a specific morphology of the transformation products corresponds to each step. The experimental data for these metals are in agreement with the kinetic theory of polymorphic transformations. The stepwise kinetics of the polymorphic transformation in iron are partly due to the slowing down of the interphase boundary by interstitial impurities. (18 refs.)

109289 Effect of disorder on the martensitic phase transformation in Nb_3Sn. C.L.Snead,Jr., H.Kumakura, M.Suenaga (Metall. & Materials Sci. Div., Brookhaven Nat. Lab., Upton, NY, USA).
Appl. Phys. Lett. (USA), vol.43, no.3, p.311-13 (1 Aug. 1983).
Specimens of Nb_3Sn tape have been irradiated at ~380K with reactor-spectrum neutrons to fluences of 1.3×10^{19} n/cm^2 ($E>1$ MeV) and the internal friction and dynamic Young's modulus measured from 6 to 300K. The softening of the lattice with decreasing temperature is seen to decrease from 40% of the room-temperature value at 10K for unirradiated Nb_3Sn to 94% at a fluence of 1.3×10^{19} n/cm^2. The internal friction δ due to tetragonal domain-wall motion of the transformed material decreased with increasing fluence, being completely suppressed after $\sim4\times10^{18}$ n/cm^2. The transformation temperature T_m decreased from ~49K for the virgin specimen to 22K for a fluence of 3.8×10^{18} n/cm^2 with no evidence of any tetragonal transformation at all for higher fluences. The lattice-dynamical and electronic changes responsible for these effects are not known at this time, but are seen to be correlated with neutron-induced disorder. (18 refs.)

109290 The relation between the martensite retransformation rate and shape memory in Cu-12.4% Al alloy. Z.Bojarski, H.Morawiec, P.Matyja (Inst. of Phys. & Chem. of Metals, Silesian Univ., Katowice, Poland).
Cryst. Res. & Technol. (Germany), vol.18, no.7, p.K86-9 (1983).
The occurrence of shape memory effect in Cu-12.5% Al alloy was first reported by Nagasawa (1971). The quenched and deformed specimen, when rapidly heated to 450°C, almost completely recovered its original shape. The authors determine the influence of reheating rate and eutectoid decomposition on percentage shape recovery. (2 refs.)

109291 Internal friction in Cu-Al-Zn alloy in the region of a reversible martensitic transformation. Z.Bojarski, J.Ilczuk, H.Morawiec (Inst. of Phys. & Chem. of Metals, Silesian Univ., Katowice, Poland).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.123-7 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of the influence of a cyclic martensitic transformation on the temperature dependence of the internal friction in an alloy of the Cu-8.5 wt.% Al-14.5 wt.% Zn composition. These temperature dependences revealed a difference in the course of the reversible martensitic transition for a sample quenched from a high temperature and one subjected to the first heating-cooling cycle. (7 refs.) *A.T.*

109292 Influence of the texture, grain shape, and substructure of austenite after warm rolling on the martensite structure. V.I.Izotov (Inst. of Metall. & Phys. of Metals, Moscow, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.139-45 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
Optical and electron microscopy were used in a study of the influence of the crystallographic texture, shape, size, and substructure of grains in austenite deformed by warm rolling on the morphology of the 'cooling martensite' and on the deformation of 80N22 and 25Kh17N6F alloys. It was found that the degree of fragmentation of the martensite in flattened textured austenite grains depended on the nature of the martensite and was governed by the angle between the habit and texture planes. Such forms of the deformed austenite structure as double twins and fragments with large-angle misorientations caused fragmentation of crystals of the resultant martensite, and twins were found to retain the FCC lattice. (11 refs.) *A.T.*

109293 Characteristic features of the phase transformation in In-Hg alloys. Y.Koyama (Dept. of Metall., Tokyo Inst. of Technol., Tokyo, Japan), H.Suzuki, O.Nittono.
J. Jpn. Inst. Met. (Japan), vol.47, no.8, p.655-62 (Aug. 1983). In Japanese.
The FCC⇌FCT phase transformation in indium-(6.8, 7.0 at%) mercury alloys has been studied by means of X-ray diffractometry and a metallographic technique. The alloys when cooled from a high temperature, corresponding to FCC phase to a temperature above room temperature, undergo a phase separation from FCC to FCC+FCT($c/a>1$). On the other hand, when they are cooled to a temperature below room temperature at a cooling rate more than 0.1K/s, the FCC→FCT martensitic transformation takes place, and surfaces of the FCT alloys show a banded relief associated with the martensitic transformation. The shape memory effect is observed in the FCT→FCC reverse transformation on heating, and the amount and behavior of shape recovery are strongly influenced by the heating rate. The characteristic features of the phase transformation are well explained by considering the effect of atomic diffusion. The FCC⇌FCT martensitic transformation is analyzed on the basis of the Landau theory, and some physical quantities such as the second-order elastic constant and change in entropy are calculated. (16 refs.)

109294 Diffuse scattering of electrons in the alloy $Ti_{50}Ni_{46}Nb_4$ during the pre-precipitation of the X-phase. A.G.Khundzhua, M.I.Zakharova (Dept. of Solid State Phys., Moscow Univ., Moscow, USSR).
Moscow Univ. Phys. Bull. (USA), vol.37, no.6, p.94-7 (1982). Translation of: *Vestn. Mosk. Univ. Ser. 3 (USSR)*, vol.37, no.6, p.81-4 (1982).
The method of diffraction electron microscopy is used to study the fine crystalline structure of the B2 solid solution in the alloy $Ti_{50}Ni_{46}Nb_4$. During an isothermal anneal at 550°C the X-phase with the face-centered cubic structure and lattice constant $a_x=2\sqrt{7}a_{B2}=15.8$ Å precipitates. Immediately after hardening of the alloy of 1100°C the body-centered cubic B2 lattice contains regions with crystal structure close to the structure of the X-phase, which are responsible for the characteristic configuration of the intense diffuse electron scattering. (6 refs.)

109295 Direct observation of transformations during heating of steels in the column of an electron microscope. M.L.Bernshteyn, L.M.Kaputkina, S.D.Prokoshkin, N.A.Nikishov.
Russ. Metall. (GB), no.3, p.71-80 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.3, p.76-89 (1982).
The compositions of the investigated steels were chosen in such a way as to enable typical morphological varieties of martensite to be obtained in them through quenching, and also different T_A values on heating. The following combinations of the type of morphology of the original martensite and T_A level were obtained: (a) packet (block) martensite, low T_A (alloy N25); (b) lamellar marteniste, low T_A (60N20); (c) packet martensite, high T_A (38KhS); (d) lamellar martensite, high T_A (120Kh6); (e) mixed (lamellar+-packet) martensite, high T_A (U8, 80Kh5). (14 refs.)

109296 Stress-induced martensitic transformation in a Ti-Ni single crystal. F.Takei (Res. Inst. for Iron, Steel & Other Metals, Tohoku Univ., Sendai, Japan), T.Miura, S.Miyazaki, S.Kimura, K.Otsuka, Y.Suzuki.
Scr. Metall. (USA), vol.17, no.8, p.987-92 (Aug. 1983).
The stress-induced transformation in Ti-Ni single crystals, which have been solution-treated at a high temperature to obtain a single parent phase, is reported. (20 refs.)

109297 Effect of titanium on the grain boundary segregation of phosphorus in Fe-Ti-P and Fe-Ti-C-P alloys and on the embrittlement of steels. H.Erhart, H.J.Grabke, R.Moller (Max-Planck-Inst. fur Eisenforschung, Dusseldorf, Germany).
Arch. Eisenhuettenwes. (Germany), vol.54, no.7, p.285-9 (July 1983).
Presents the results of an investigation on equilibrium segregation of phosphorus at the grain boundaries of Fe-Ti-P and Fe-Ti-C-P alloys, and its reduction by binding with Ti, by displacement from the grain boundaries by C and by trapping at TiC precipitates. Finally, grain boundary segregation of P in deep drawing steels and the effects of C and Ti contents are discussed. (16 refs.)

109298 Time dependence at 550 and 700°C of $M_{23}C_6$ precipitate composition in AISI 304 stainless steel. A.Boeuf, R.Caciuffo, S.Crico, R.Rebonato, F.Rustichelli (Comm. of the European Communities, JRC, Ispra, Italy), J.P.Morlevat.
Mater. Lett. (Netherlands), vol.2, no.1, p.49-52 (July 1983).
The time dependence at 550 and 700°C of $M_{23}C_6$ precipitate composition in AISI 304 stainless steel has been investigated using the X-ray fluorescence induced by electron bombardment. By increasing the ageing time, $M_{23}C_6$ precipitates become enriched in Cr and depleted in Fe. (7 refs.)

109299 A study of antimony segregation in Fe-Ni alloys. L.S.Burmaka, V.Hajko, O.M.Ivasishin, Yu.N.Ivashchenko, V.Karel, V.G.Kostyuchenko, A.Kosturiak (Inst. of Phys. of Metals, Acad. of Sci., Kiev, Ukrainian SSR).
Phys. Met. (GB). Translation of: Metallofizika, Kiev (USSR), vol.4, no.3, p.566-72 (1982). [received: Aug. 1983]
Antimony segregation in Fe-30% Ni type alloys is examined using fractographic and chemical analysis, Auger electron spectroscopy and secondary-ion mass spectroscopy. Antimony is shown to segregate in a thin surface layer at the grain boundaries, the level of segregation and the layer structure being dependent on heat treatment conditions and responsible for the fracture behavior of the alloys. The presence of Fe_3Sb_2 precipitates at grain boundaries after long holding treatment increases the contribution of intercrystalline ductile fracture. (6 refs.)

109300 Characteristics of precipitation of a supersaturated solid solution in Al-Zn alloy. A.N.Baranovskii, R.R.Romanova, V.G.Pushin (Inst. of Metal Phys., Ural Sci. Centre, Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.146-54 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The fine structure of samples of Al-30 wt.% Zn alloy was investigated by electron microscopy after low- and high-temperature ageing. It was found that the metastable phases (rhombohedral α_R' and cubic α') precipitated in the alloy were due to a single isostructural process and they differed from one another by the degree of coherence with the matrix. This isostructural precipitation (Guinier-Preston zones$\rightarrow\alpha_R'\rightarrow\alpha'$) was a 'dead-end' process and had only an indirect influence on the formation of precipitates of the stable β-phase. The occurrence of two orientational relationships between the β-phase and the matrix was observed for the first time. The sequence of formation of phases during precipitation of the supersaturated solid solution in alloys of the Al-Zn system was analyzed. (16 refs.) *A.T.*

109301 Grain-boundary segregation in low-alloy titanium-vanadium alloys. G.I.Kolodkina, I.I.Kryukov, A.I.Rybnikov, S.S.Ushkov (I.I. Polzunov Sci.-Industrial Combine on Investigation & Design of Power-Industry Equipment, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.160-4 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
Two characteristic features were observed for these alloys after heat treatment and these features distinguished them from technical-purity titanium. Firstly, there was a strong reduction (and in the case of alloys with 1-2% V a complete absence) of embrittlement in the region of 500°C. Secondly, after ageing at 850°C the impact strength decreased considerably compared with that in the initial state and that found after heat treatment at 700 and 900°C. A very important result was that at moderate temperatures corresponding to the α-phase range the presence of vanadium slowed down precipitation from the α-matrix of such low-solubility elements as iron and nickel. Moreover, vanadium increased the thermal stability of the mechanical properties of titanium. (10 refs.) *A.T.*

109302 Homogeneous nucleation of a precipitating phase in ordering alloys with domain walls. V.D.Sukhanov, O.D.Shashkov (Inst. of Metal Phys., Ural Sci. Centre, Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.165-70 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
Homogeneous nucleation of a new phase was observed in several ageing and ordering alloys in the Cu-Pd-Ag and Cu-Pd-Fe systems, in spite of the existence in the ordered matrix of defects in the form of domain walls. It was established that the formation of three-dimensional networks of precipitates along domain walls in these alloys could occur during the particle coagulation stage. (11 refs.) *A.T.*

109303 On precipitation in rapidly solidified aluminium-silicon alloys. P.van Mourik, E.J.Mittemeijer, Th.H.De Keijser (Lab. of Metall., Delft Univ. of Technol., Delft, Netherlands).
J. Mater. Sci. (GB), vol.18, no.9, p.2706-20 (Sept. 1983).
The precipitation of silicon in rapidly solidified Al-Si alloys was studied. For alloys with 2.4 and 11.0 wt.% Si (2.3 and 10.3 at.% Si, respectively) the lattice parameters of the Al-rich and of the Si-rich phases were measured after ageing at 397, 425 and 448K. For alloys with 2.6 and 13.0 wt.% Si crystallite sizes and lattice strains were determined by analysis of the X-ray diffraction line broadening. After ageing the lattice parameters of the Al-rich and the Si-rich phases were influenced by the difference in thermal expansion between both phases. After correction for this effect the amount of silicon dissolved in the Al-rich phase was estimated as a function of ageing time. The behaviour of the lattice microstrains on ageing was explained as a result of the disappearance of stresses due to quenching and the introduction and subsequent dissipation of stresses due to precipitation. After completed precipitation stresses due to the difference in thermal expansion between both phases still exist at room temperature. (45 refs.)

109304 A preliminary study of precipitation in Ti^{4+}-doped polycrystalline alumina. R.A.Langensiepen, R.E.Tressler, P.R.Howell (Dept. of Materials Sci. & Engng., Pennsylvania State Univ., University Park, PA, USA).
J. Mater. Sci. (GB), vol.18, no.9, p.2771-6 (Sept. 1983).
Precipitation processes in two titanium-doped aluminas (0.14 and 0.60 cation % titanium) have been examined using a variety of analytical electron micro-

scopy techniques. The results strongly suggest that, for an ageing temperature of 1573K, rutile is the only precipitate formed in the 0.14 cation % titanium material. However, evidence for the precipitation of both rutile and β-Al_2TiO_5 (the latter at triple junctions) was obtained in the 0.60 cation % titanium sample. (11 refs.)

109305 Precipitation of $Mg_2Zr_5O_{12}$ in MgO-partially-stabilized ZrO_2. S.C.Farmer, L.H.Schoenlein, A.H.Heuer (Dept. of Metall. & Materials Sci., Case Inst. of Technol., Case Western Reserve Univ., Cleveland, OH, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.C107-9 (July 1983).
Decomposition of cubic, MgO-stabilized ZrO_2 solid solutions has been studied. Precipitates of the ordered compound, $Mg_2Zr_5O_{12}$, form, but only when a two-stage heat treatment involving nucleation at a low temperature followed by growth at a higher temperature is used. Other decomposition products are also present after such a heat treatment. (12 refs.)

109306 A study of a cellular phase transformation in the ternary Ni-Al-Mo alloy system. M.J.Kaufman, J.A.Eades (Dept. of Metall., Univ. of Illinois, Urbana, IL, USA), M.H.Loretto, H.L.Fraser.
Metall. Trans. A (USA), vol.14A, no.8, p.1561-71 (Aug. 1983).
Orthorhombic Ni_3Mo has been observed as a product of a cellular precipitation reaction occurring at grain boundaries in both Ni-12Al-15Mo and a ternary eutectic Ni-12.8 Al-22.2Mo (compositions in at.%) when heat treated at intermediate temperatures (600 to 850°C). Convergent beam electron diffraction and energy dispersive X-ray spectroscopy techniques have been employed to characterize the structure and composition of this phase in these alloys. Since this phase is usually heavily faulted, the diffraction symmetries are reduced, causing ambiguities in analysis. Therefore, a binary (nominally) stoichiometric Ni_3Mo alloy was produced and heat treated in a manner designed to minimize faulting. Convergent beam patterns obtained from this material exhibited symmetries that identify it as having the mmm point group; further analysis of the diffraction patterns led to the conclusion that the space group is Pmmm. These patterns were then used to aid in the interpretation of those taken from the ternary alloys. Orthorhombic Ni_3Mo was also observed within the grains of the ternary eutectic alloy following prolonged aging treatments; the orientation relationship between the Ni_3Mo and the FCC matrix was determined to be identical with that in the cellularly transformed regions. (18 refs.)

109307 Effect of the application of uniaxial stress on precipitation in an Al(Cu) alloy. S.Kawarazaki, N.Kunitomi (Faculty of Sci., Osaka Univ., Osaka, Japan), R.M.Nicklow, H.G.Smith.
Physica B & C (Netherlands), vol.120B+C, no.1-3, p.401-4 (May 1983). (Yamada Conference VI on Neutron Scattering in Condensed Matter, Hakone, Japan, 1-4 Sept. 1982).
The effects of uniaxial stress applied during the aging time for precipitation growth on the formation of GP zones in an Al-1.8% Cu alloy have been studied by means of neutron scattering. When a compression is applied along the [100] direction the precipitates grow preferentially on the (100) planes. Making use of this result, the effect of the formation of GP zones on the resonance anomaly in the [ζ00]T phonon branch previously observed in the alloy has also been studied with respect to the relative direction between the phonon wave vector **q** and the plane of the precipitate. The experimental result indicates that the precipitates perpendicular to **q** are more effective for the formation of the resonance anomaly than those parallel to **q**. (2 refs.)

109308 Conditions for combined precipitation of sulphide and nitride phases in silicon iron. B.M.Mogutnov, L.A.Shvartsman, A.A.Kononov.
Russ. Metall. (GB), no.2, p.90-5 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.104-9 (1982).
To obtain particles of sulphide inhibitor phase of the required dispersion in silicon iron the cooling rates in hot rolling must be the greater, the higher the temperatures (T_p) of complete solution of MnS; and rolling must be started at a temperature no lower than T_p. The volume fraction of inhibitor phases in the sulphide variant of inhibition can be increased by using the nitrogen dissolved in the steel and harmonising the thermodynamic conditions for MnS and AlN precipitation. For this purpose, steel of the optimal composition for this technology should be alloyed with not more than 0.030% aluminium. When boron nitride is used as the additional inhibiting phase iron boride can be formed at hot-rolling temperatures. Austenite formation at these temperatures somewhat lowers the temperature of complete BN solution. (13 refs.)

109309 Precipitation of metastable and equilibrium phases in the decomposition of the β-solid solution in zirconium alloys. M.I.Zakharova, A.A.Aminov, A.G.Khundzhua.
Russ. Metall. (GB), no.3, p.66-70 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.3, p.71-5 (1982).
Phase transformations in zirconium alloys with Nb, Mo, Al, V and Re in the decomposition of the high-temperature BCC solid solution, which is in the metastable state after quenching from 1100°C, were studied. (9 refs.)

109310 Precipitation of helium and its effects on mechanical properties of metals. H.Trinkaus (Inst. fur Festkorperforschung, KFA Julich, Julich, Germany).
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.312-18
A survey of the precipitation of He in metals is presented. Low temperature precipitation is associated with athermal processes like metal interstitial emission and loop punching. The related extremely high He densities and experimental techniques to study them are discussed. High temperature precipitation is presented as a typical example of a thermal two-component nucleation-process. It is shown that under certain conditions the evolution of a He bubble population can give information on the permeation of He. Finally, the effects of the formation of He bubbles on mechanical properties of metals is discussed. (33 refs.)

81.40 TREATMENT OF MATERIALS AND ITS EFFECTS ON MICROSTRUCTURES AND PROPERTIES

109311 Microindentation kinetics at premelting temperature. V.G.Kononenko, Chan Kueu Zung.
Ukr. Fiz. Zh. (USSR), vol.28, no.8, p.1198-203 (Aug. 1983). In Russian.
The microindentation kinetics is investigated at premelting temperature. Analysis of possible pit formation mechanisms shows that an experimentally observed anomaly of a rapid indentor dip may be connected with spontaneous generation of dislocation and anomaly of high dislocation mobility at premelting temperature. 109312 Development of a new grade of stainless maraging steel and its aging characteristics. P.P.Sinha, A.Natarajan, K.V.Nagarajan, B.K.Sarkar (Vikram Sarabhai Space Centre, Trivandrum, India).
Trans. Indian Inst. Met., vol.35, no.2, p.98-107 (April 1982). [received: Aug. 1983]
A new stainless maraging composition containing 8% Ni, 11% Cr, 5.2% Mo, 12.4% Co and 0.1% Ti has been developed to yield a maximum UTS of around 175 kg/mm^2 coupled with 6.8% elongation. The aging characteristics of this steel in the temperature range 350° to 600°C for durations up to 15 hours have been studied using hardness measurement and metallography techniques. The alloy shows age-hardening behaviour similar to conventional maraging steel. The precipitation reaction occurs by a pipe diffusion mechanism in the dislocation rich matrix. The basic strengthening precipitate has been identified as needles of Fe_2Mo. Also the Fe-Cr-Mo χ-phase having typical Widmannstatten structure has been observed to precipitate in highly segregated regions. The presence of χ-phase and banded structure has not been found to affect the tensile properties, but they impair the impact strength considerably. The aging reaction is also accompanied by reversion of martensite to austenite. (18 refs.)

109313 Precipitation hardening in surface layers of an aluminium-zinc-magnesium alloy. B.Jayakumar, N.K.Srinivasan (Dept. of Metall. Engng., PSG Coll. of Technol., Coimbatore, India).
Trans. Indian Inst. Met., vol.35, no.2, p.167-70 (April 1982). [received: Aug. 1983]
Experimental investigations relating to the response of precipitation hardening in the surface layers of an Al-Zn-Mg alloy are reported. Microhardness as well as bulk hardness measurements were made on specimens of varying thickness. During natural aging, thin specimens of 3.75 mm thickness failed to develop sufficient hardness in the surface layers, while the bulk hardness increased rapidly in the first few hours. Two stages were observed in the natural aging behaviour. For artificial aging, thicker specimens hardened at a lower rate than thin specimens. The results are interpreted in terms of vacancy losses and vacancy magnesium interaction in the surface layers. (16 refs.)

109314 On the theory of acoustic softening of low-carbon steel. I.K.Vagapov, S.A.Kirillov, V.V.Klubovich (Inst. of Solid State & Semiconductor Phys., Acad. of Sci., Minsk, Byelorussian SSR).
Phys. Met. (GB). Translation of: Metallofizika, Kiev (USSR), vol.4, no.3, p.557-65 (1982). [received: Aug. 1983]
The effect of acoustic softening of low-carbon steel was examined using the Gilman-Johnston dislocation model. Under the assumption of the superimposition of static and acoustic stresses, the stress-strain diagram was estimated

numerically for uniaxial tension of low-carbon steel by application of ultrasonics. Variation of the average velocity and density of mobile dislocations during ultrasonic-affected tension was investigated. A microscopic-level interpretation of the acoustic softening effect was provided and compared with experiment. (14 refs.)

109315 Investigation of 'reverse solution' in beryllium bronze. Kh.G.Tkhagapsoev (Kabardino-Balkarsk State Univ., USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.818-22 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.54-7 (Nov. 1982).
Short heating to 500°C of beryllium bronzes hardened and aged at 300-340°C and also aged after cold plastic deformation was found to lead to softening as the result of reverse solution. The efects of reverse solution were caused by the dispersion of the structure and did not depend upon the nature of the precipitate phases. Beryllium bronze acquired resistance to reverse solution if in aging the α-solid solution decomposition occurred according to the interrupted precipitation mechanism. Treatment for reverse solution at 500°C with a hold of 10 sec may be used as a method of softening of beryllium bronzes in place of the traditional intermediate hardening. (7 refs.)

109316 Increasing the operating life of BrB2 bronze bellows. I.G.Dobrovol'skii, T.M.Khonyak, V.S.Shlyakhovoi (Polytech. Inst., Belorussian SSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.822-4 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.58-9 (Nov. 1982).
A reduction in the hardening temperature of BrB2 bronze from 780 to 720°C was found to make it possible to increase the service life by more than 1.5 times as the result of grain refinement. The small decrease in tensile strength after low temperature hardening had practically no influence on the hysteresis of bellows. (no refs.)

109317 Precipitation hardening caused by a difference in shear modulus between particle and matrix. E.Nembach (Inst. fur Metallforschung, Univ. Munster, Munster, Germany).
Phys. Status Solidi a (Germany), vol.78, no.2, p.571-81 (16 Aug. 1983).
The interaction force between a spherical precipitate, whose shear modulus differs from the one of the matrix, and a dislocation is calculated numerically. From the maximum and the range of this interaction force, the critical resolved shear stress τ_c is derived. If the total precipitated volume fraction stays constant and the particle radius r_p is varied between 8 and 50 times, the Burgers vector, τ_c increases monotonously with r_p. This is in contrast to the findings published by other authors. Modulus hardening is weak compared with other mechanisms of precipitation strengthening. (18 refs.)

109318 Hardening by thermal vacancies and quenching strains in singly-oriented Pb single crystals. A.R.Yavari (Lab. de Thermodynamique et Phys.-Chimie Metall., Domaine Univ., St. Martin D'Heres, France).
Phys. Status Solidi a (Germany), vol.78, no.2, p.583-8 (16 Aug. 1983).
Yield strength measurements at 77K on singly-oriented Pb single crystals of easy glide orientation, quenched and reheated to various temperatures reveal a two stage evolution with increasing post-quenching annealing temperatures. The temperature of the two stages correspond to those obtained by resistivity measurements and are interpreted in terms of formation and annealing out of vacancy clusters. It is shown that the observed quench-hardening of up to 500% is well represented by a mechanism where moving dislocations must create jogs to pass through a random distribution of vacancy clusters. A large reproducible contribution of quenching strains to the hardening is isolated by treatments excluding thermal vacancy supersaturation. It is found that strain generated dislocations alone cannot account for this hardening, thus suggesting a large contribution from strain generated vacancies. (16 refs.)

109319 Toughening of structural ceramics. P.Boch (CNRS ENSCI, Limoges, France), G.Fantozzi, G.Orange.
Rev. Int. Hautes Temp. & Refract. (France), vol.19, no.3, p.119-57 (1982). In French.
The use of 'structural' ceramics to build high efficiency thermal engines is impeded by the brittleness of these materials, which explains the efforts to improve their toughness. Part one of this paper gives a short review of the ways which have been chosen: development of new compounds with high specific toughness, compressive loading of the pieces, fibrous composites and composites with dispersed phases. This latter case is studied on the example of zirconia based ceramics, mainly partially stabilised zirconia. Part two of the paper is devoted to the various mechanisms occurring in the zirconia based ceramics: constrained phase transformation from the tetragonal to the monoclinic phase and microcracking related to such a transformation. The present theories about the improvement of toughness are summed up and discussed. (90 refs.)

109320 Formation and thermal stability of an oxide dispersion in a rapidly solidified Ti-Er alloy. D.G.Konitzer (Dept. of Metall., Univ. of Illinois, Urbana, IL, USA), B.C.Muddle, H.L.Fraser.
Scr. Metall. (USA), vol.17, no.7, p.963-6 (July 1983).
It was found that the cooling rates associated with laser surface melting are sufficiently rapid to retain a supersaturated solid solution of Er in Ti at ambient temperature. Heat treatment of this rapidly solidified material at 973K leads to the formation of a refined dispersion of Er_2O_3 in Ti where the particle size is ~5-25 nm. Prolonged aging at 973K produces little change in the scale of the dispersion, and thus demonstrates a thermal stability that might well be exploited in design of alloys for elevated temperature applications. 109321 Hardness changes during ferrite recrystallization in microalloyed steels. P.Deb, V.Raghavan (Indian Inst. of Technol., New Delhi, India).
Trans. Indian Inst. Met., vol.35, no.5, p.461-5 (Oct. 1982). [received: Aug. 1983]
The hardness changes and the ferrite recrystallization kinetics have been studied for different thermomechanical treatments in three microalloyed steels and a reference C-Mn steel. The hardness decreases most rapidly in the first five minutes of the recrystallization anneal. The rate of change of hardness decreases continuously with increasing log (annealing time) in the C-Mn steel. In microalloyed steels, the hardness versus log of annealing time often enters a relatively flat region, before the hardness drop increases again. An approximate linear relationship is observed in all cases between the recrystallized volume fraction and the corresponding hardness. For all steels, the hardness is more for a given volume fraction of recrystallized ferrite, after annealing at a lower temperature. In addition, the hardness-versus-recrystallized fraction plots exhibit quite different slopes. The graphs corresponding to different annealing temperatures for the C-Mn-Nb-V steel show a diverging trend, as the recrystallized fraction increases. This behaviour is attributed to the additional softening effect resulting from coarsening of alloy carbide particles at the higher temperatures of the recrystallization anneal. (4 refs.)

109322 Structural and magnetic studies of pure and substituted gamma iron oxide. V.Prakash, V.Rao, S.Pramanik (Nat. Metall. Lab., Jamshedpur, India).
Trans. Indian Inst. Met., vol.35, no.5, p.513-15 (Oct. 1982). [received: Aug. 1983]
Gives a brief description of methods of preparation of pure and Co-substituted gamma iron oxide. Experimental characterisation of powders by X-ray diffraction, electron microscopic and magnetic studies have been described. Mossbauer studies have also been carried out. (12 refs.)

109323 Universal dependence of the metal hardening parameters on the intensity of shock action. A.A.Deribas, V.F.Nesterenko, T.S.Teslenko.
Combust. Explos. & Shock Waves (USA), vol.18, no.6, p.670-5 (Nov.-Dec. 1982). Translation of: *Fiz. Goreniya & Vzryva (USSR)*, vol.18, no.6, p.68-74 (Nov.-Dec. 1982).
On the basis of an analysis of available experimental results, the authors arrive at the deduction that the fundamental quantity governing the residual properties of materials after shock-wave landing is the pressure on the wave-front in a 1-10 μsec shock compression time range. (33 refs.)

109324 Influence of heat treatment conditions on recrystallization in Fe-3% Si alloy after critical deformation. L.D.Kurmaeva, B.K.Sokolov, L.V.Smirnov (Inst. of Metal Phys., Acad. of Sci., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.204-6 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of the influence of the size of the matrix grain on the critical strain ϵ_{cr} needed for the formation of a coarse-grained structure. An allowance was made for the existence of texture. An increase in the initial grain size increased the critical strain irrespective of the texture and the state of the second phase affected both ϵ_{cr} and the critical grain size. An increase in the degree of dispersion of particles of the second phase in samples with the same grain size and the same texture increased ϵ_{cr}. (8 refs.) *A.T.*

109325 Recovery in deformed copper and nickel single crystals. R.E.Cook, G.Gottstein, U.F.Kocks (Materials Sci. Div., Argonne Nat. Lab., Argonne, IL, USA).
J. Mater. Sci. (GB), vol.18, no.9, p.2650-64 (Sept. 1983).
The static recovery behaviour of copper and nickel single crystals deformed in multiple slip was investigated in mechanical tests and in HVEM in situ annealing experiments. Recovery of Type I, as previously identified in aluminium, was observed in both its microscopic and macroscopic features: a sharpening of the cell-wall structure without a change in substructure scale, correlated with a short transient in the strain-hardening behaviour during retesting. The substructure development with increasing recovery time and temperature is similar to that during dynamic recovery, i.e. with increasing strain in a continuous test. After longer recovery times or at higher annealing temperatures the specimens recrystallize; after larger strains they recrystallize dynamically. An intermediate stage akin to the Type II recovery found in aluminium was never observed, either in its macroscopic manifestation of a long reloading transient or as a general coarsening of the subgrain structure. Examples of local sub-boundary mobility and dissolution were, however, seen in situations close to static or dynamic recrystallization. (40 refs.)

109326 The quantitative representation of fiber- and sheet-texture in metals in cubic crystal system. I. Computer programs for texture analysis. Huhn Jun Kim, Chang Young Lee, Soon Chul KIM, Byung Chil Chun.
J. Korean Inst. Met., vol.21, no.5, p.459-68 (May 1983). In Korean.
Texture measurements by the neutron diffraction method are analyzed using Bunge's series expansion method and the effect of series truncation is studied for samples of various texture sharpness. Two computer programs, TXFIB and TXSHT, developed for the analysis of the respective fiber- and sheet-type texture, are described. Using these computer programs, the orientation distribution function can be expanded in the series of generalized spherical harmonics up to the 58th term from 6 experimental pole figures as input. Estimations of various errors involved in the texture analysis and texture sharpness index are also included in the programs. (18 refs.)

109327 On the recovery and annealing kinetics of cold-worked Ni-4.5 at% Cu alloy. A.R.Ali (Phys. Dept., Cairo Univ., Giza, Egypt), G.Said.
Phys. Status Solidi a (Germany), vol.78, no.2, p.463-7 (16 Aug. 1983).
The process of recovery in cold-worked Ni-4.5 at.% Cu alloy is investigated in the temperature range 25 to 1000°C by observing the associated changes in electrical resistance and magnetic susceptibility. Two annealing stages centred around 130 and 320°C are observed with corresponding activation energies of 1.1 and 1.5 eV, respectively. These are attributed to the release of interstitials trapped on impurity Cu atoms and to the migration of vacancies with the possible formation of vacancy-Cu pairs or complex aggregates, respectively. Above 550°C, the recovery process is examined by using both grain size and susceptibility measurements. At the start of the high annealing process the activation energy (E) is found to be 3.6 eV and the process is related to the climb motion of dislocations. The increase in E with the annealing process is climb motion of dislocations. The increase in E with the interpreted in terms of the initiation of another annealing reaction with complex kinetics and assigned to the formation of low-angle subgrain boundaries. (9 refs.)

109328 Solid solution hardening of Cd-Zn single crystals at 1.5, 2.8, and 4.2K. V.Navratil, M.Hamersky (Dept. of General Phys., J.E. Purkyne Univ., Brno, Czechoslovakia), P.Lukac, V.P.Soldatov, V.I.Startsev.
Phys. Status Solidi a (Germany), vol.78, no.2, p.633-8 (16 Aug. 1983).
Cd-Zn single crystals are deformed in creep at temperatures of 1.5, 2.8, and 4.2K. From the creep experiments the work hardening curves are constructed and the critical resolved shear stress is found to increase with $c^{2/3}$ where c is the atomic concentration of zinc as solute. The concentration dependence of the critical resolved shear stress can be explained according to the theory of Labusch (1972). (29 refs.)

109329 Application of the boundary value integral equations method to the investigation of press working of metals. P.I.Polukhin, V.P.Polukhin, N.F.Andrianov, A.V.Novikov.
Russ. Metall. (GB), no.1, p.153-6 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.179-84 (1982).
The possibility of employing a method involving boundary value integral equations in the investigation of press working of metals is substantiated. Application of this method makes it possible to reduce substantially computer time in the numerical investigation of such problems because the dimensionality is reduced. (13 refs.)

109330 Examination of the recrystallisation of copper deformed at high strains. A.V.Burov, S.D.Shevelkin.
Russ. Metall. (GB), no.1, p.145-7 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.169-72 (1982).
An increase in the total strain to 90% and in the initial strength of rolled copper strips is accompanied by an increase in the strength of the thermodynamic stimulus to recrystallisation. Consequently, the softening temperature of highly deformed copper decreases to 400°C. The higher recrystallisation susceptibility of highly deformed copper, hardened during ageing after working, makes it possible to reduce additionally the temperature of production annealing of copper strips to 300-350°C. (11 refs.)

109331 Conditions of closing pores and voids by working cast metal. V.M.Segal, D.A.Pavlik.
Russ. Metall. (GB), no.1, p.156-60 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.184-8 (1982).
An equation has been obtained for the change of porosity of cast metal during its plastic deformation. Criteria for the welding of microdefects by a hot working process are proposed. Distinctive features of welding of macrovoids by working the metal in nonuniform states of stress and strain are considered. The possibility of complete welding of voids by working cast metal in simple shear is shown. (4 refs.)

109332 Investigation of residual stresses in wire drawing. Yu.I.Nyashin.
Russ. Metall. (GB), no.1, p.160-3 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.188-91 (1982).
The nature of residual stress distribution in a real production process of cold drawing of a steel wire has been studied as well as the dependence of the stress distribution on the conditions in which the deformation process is carried out. Ways of improving the quality of the product by reducing the residual stresses are considered. (8 refs.)

109333 Dynamic recovery and dynamic recrystallization. L.N.Larikov.
Russ. Metall. (GB), no.2, p.62-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.69-76 (1982).
During the hardening with a high degree of perfection only those defects which appeared during hardening can be dynamically removed. In the case of real materials both the newly formed and the previously present lattice defects can be dynamically removed. The dynamic recovery includes: dynamic relaxation of point defects, annihilation of dislocations with opposite signs, dynamic polygonisation of three types and dynamic recovery with reorientation. Dynamic primary recrystallisation, dynamic collecting recrystallisation and dynamic secondry recrystallisation can occur depending on the type of material and the conditions of its deformation. Processes of dynamic recrystallisation seldom occur in the pure form; as a rule they are accompanied by dynamic recovery. (23 refs.)

109334 Properties of structural aluminium alloys in the recrystallised and polygonised states. V.I.Dobatkin.
Russ. Metall. (GB), no.2, p.68-72 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.76-81 (1982).
On the basis of the results of testing thermally hardened aluminium alloys with recrystallised and polygonised structures, the application of materials with a polygonised structure is recommended for all cases of comparatively short operating periods and in a majority of cases for articles with a higher resource. The limit factors for higher resource materials could be the lamination corrosion and long term strength at elevated temperatures. These characteristics should be experimentally checked in respect of the operating conditions of the structure. (9 refs.)

109335 The formation of vacancies during primary recrystallisation. S.S.Gorelik, M.S.Blanter.
Russ. Metall. (GB), no.2, p.79-82 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.90-4 (1982).
During the primary recrystallisation of metals and alloys, a considerable amount ($>10^{-4}$) of excess vacancies is formed. Apparently, this is due to annihilation of dislocations and absorption of dislocations by migrating boundaries. The 'recrystallisation' vacancies have a prolonged accelerating influence on the diffusion and some influence on other structurally sensitive phenomena and properties. This influence is manifested particularly strongly after high degrees of deformation and high velocities of the recrystallisation heating. A long effective 'time of existence' of the 'recrystallisation' vacancies and the influence of the velocity of heating on it, can be explained by the high probability of the formation of accumulations of these vacancies (vacancy, clusters, submicropores) and subsequent 'dissolution' of these accumulations by vacancies feeding the material. Excess vacancies formed during the recrystallisation after work hardening can be utilised for acceleration of some processes. (14 refs.)

109336 Effect of oriented aluminium nitride precipitates on the texture in 3% silicon iron. R.I.Malinina.
Russ. Metall. (GB), no.2, p.98-104 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.113-19 (1982).
The precipitation of AlN nitrides in 3% silicon iron and also the presence of other nonmetallic inclusions lead to an increase in the dislocation density in the already recrystallised metal. Consequently, grain refinement takes place during HTA at 800-900°C. The oriented precipitates of the AlN nitrides together with the quenching stresses result in the formation of a three-dimensional elasto-anisotropic stress state in the microregions which causes preferential growth of the nuclei with cubic orientation during HTA and consequently increases the proportion of the cubic component of the texture. (14 refs.)

109337 Influence of cold deformation on the structural stability and heat-resisting properties of 15Kh1M1F steel. M.B.Balakhovskaya, N.A.Khusainova, E.I.Gofman.
Russ. Metall. (GB), no.2, p.133-4 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.147-9 (1982).
15Kh1M1F steel was subjected to heat treatment involving normalisation and annealing at 1050°C, with subsequent high-temperature tempering at 750°C with holding for 10 h. This heat treatment resulted in two structure variants, high-tempered bainite and ferrite-carbide mixture. The metal was then subjected to cold plastic deformation by extension. The degree of deformation was 11-13%. Heat-resistance tests were carried out at 570°C. It was found that cold plastic deformation has a considerable influence on the stability of heat-resisting steel. The bainitic structure is the more stable under conditions of prolonged high-temperature heating of 15Kh1M1F steel subjected to cold plastic deformation, but for the undeformed steel the ferrite-carbide structure is more stable. (2 refs.)

109338 Effects of hardening and localization of strain in strain aging of technical purity iron. Yu.P.Gul', M.M.Ryabchii, V.V.Ryabchii, I.F.Kaminskaya (Dnepropetrovsk Metall. Inst., Dnepropetrovsk, USSR).
Strength Mater. (USA), vol.14, no.10, p.1381-5 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.82-5 (Oct. 1982). [received: Sept. 1983]
The hardening effect in strain aging of Armco was found to increase with an increase in the degree of preliminary strain by tension (by increasing the density of introduced dislocations) regardless of the character of strain distribution in the sample if the aging time was sufficient for occurrence of hardening according to the 'stopper' mechanism. With nonuniform strain distribution in the sample (completion of preliminary strain within the limits of 'geometric loss of strength'). Intensification of strain hardening in strain aging was accompanied by strengthening of the tendency of strain aged technical purity iron toward localization of strain. Equations were obtained making it possible to describe the influence of strain aging on localization of strain in uniaxial tension. (10 refs.)

109339 Rapid thermal annealing of Se and Be implanted InP using an ultrahigh power argon arc lamp. A.N.M.M.Choudhury, K.Tabatabaie-Alavi, C.G.Fonstad (Dept. of Electrical Engng. & Computer Sci., MIT, Cambridge, MA, USA), J.C.Gelpey.
Appl. Phys. Lett. (USA), vol.43, no.4, p.381-3 (15 Aug. 1983).
A 100-kW water-walled DC argon arc lamp has been used for the first time to post anneal ion-implanted InP samples. Temperatures as high as 925°C and short cycle times (3 and 10 s) are used for the process. Se and Be were ion implanted into room temperature and hot substrate InP samples. A sputter deposited SiO_2 layer, 120 mm thick, covering all wafer surfaces was used as an encapsulant during the lamp anneal. Hot substrate Se implants (400 keV, 1.8×10^{14} cm^{-2}, 200°C) show an average mobility of 1415 cm^2/Vs and an activation of ~63%, and room-temperature Be implants (50 keV, 3.35×10^{13} cm^{-2} and 150 keV, 5.74×10^{13} cm^{-2}) an average mobility of 88 cm^2/Vs and activation of ~45%. This annealing technique is straightforward and gives activations and mobilities comparable to, or better than, the best furnace anneals with shape profiles and simplified surface encapsulation. (12 refs.)

109340 Rapid thermal annealing of Be, Si, and Zn implanted GaAs using an ultrahigh power argon arc lamp. K.Tabatabaie-Alavi, A.N.M.Masum Choudhury, C.G.Fonstad (Dept. of Electrical Engng. & Computer Sci., MIT, Cambridge, MA, USA), J.C.Gelpey.
Appl. Phys. Lett. (USA), vol.43, no.5, p.505-7 (1 Sept. 1983).
The use of a 100-kW water-walled DC argon lamp to anneal ion-implanted GaAs is reported. Annealing cycles of 3 and 10 s and peak temperatures from 950 to 1200°C have been used to anneal Be, Si, and Zn implanted, following

representative implant schedules of technological importance. It is demonstrated that this technique is superior to conventional furnace anneal techniques in terms of the doping profiles, peak carrier concentrations, activation efficiencies (particularly at high doses), and mobilities achieved. The annealing technique should be applicable to large volume GaAs integrated circuit production and 100-mm-diam wafers can be annealed in a single exposure with better than 2% temperature uniformity (Si data). (12 refs.)

109341 Banding in the microstructure of hot strip of HSLA steel. R.Kaspar, Q.Chen, A.Streisselberger (Max-Planck-Inst. fur Eisenforschung, Dusseldorf, Germany).
Arch. Eisenhuettenwes. (Germany), vol.54, no.7, p.273-6 (July 1983). In German.
Presents results of simulation of hot rolling by plane strain compression tests. Finishing temperatures, cooling rate and coiling temperature as important parameters are discussed. The elimination of banding due to activation of ferrite formation is also discussed. (10 refs.)

109342 Influence of heat treatment on structure and properties of a HSLA steel. Z.A.Chaudhury, D.S.Sarma (Dept. of Metall. Engng., Banaras Hindu Univ., Varanasi, India).
Trans. Indian Inst. Met., vol.35, no.2, p.119-25 (April 1982). [received: Aug. 1983]
The influence of annealing, normalizing, oil quenching and water quenching treatments on the microstructure and mechanical properties of a high strength low alloy steel containing 0.1% C, 1% Cr, 1.5% Mn, 0.2% V and 0.003% B has been studied. The annealed steel shows a banded structure of ferrite and pearlite while the normalized steel exhibits a mixture of ferrite and granular bainite. Transmission electron microscopic studies show that the granular bainite structure in this steel is similar to that of upper bainite. The oil-quenched and water-quenched steels possess the lath martensite structure with effects of autotempering in the former. In the normalized condition the steel has yield and ultimate tensile strengths of 609 and 788 MPa respectively with 28% elongation, properties typically observed for bainitic steels. (10 refs.)

109343 Thermomechanical treatment of a commercial purity Al-Mg-Si alloy. S.V.S.Narayana, C.S.Harendranath, A.K.Mallik (Indian Inst. of Technol., Bombay, India).
Trans. Indian Inst. Met., vol.35, no.5, p.421-31 (Oct. 1982). [received: Aug. 1983]
A study has been made on the influence of thermomechanical treatments on the ageing response of a commercial purity Al-Mg-Si alloy. While cold working prior to ageing (T8 treatment) reduced the ageing response of the alloy, cold working after a preageing treatment (T10 treatment) resulted in certain beneficial effects on the ageing behaviour of the alloy. The T10 treatment also resulted in slightly improved tensile properties. Heat treatment was found to have no effect on the low-cycle fatigue response of the alloy. Dislocation substructures studied around the fatigue fracture region showed variation with heat treatment. The alloy, in the conventionally aged condition, compared well with a superpure alloy in so far as ageing behaviour and tensile properties are concerned. However, low cycle fatigue behaviour was found to be poor. (19 refs.)

109344 On the microstructure of quenched, normalized and full-annealed, copper-modified 4340 steel. F.H.Samuel (Metall. Div., Nat. Res. Center, Cairo, Egypt), A.A.Hussein.
Trans. Indian Inst. Met., vol.35, no.6, p.615-23 (Dec. 1982). [received: Aug. 1983]
Presents a collection of some significant microstructural features that have been observed in a Cu-modified 4340 steel heat treated according to four schedules: brine quench, oil quench, normalizing and full annealing. By analogy to Cu-free 4340 steel, a lower extent of retained austenite was observed in the oil quenched state and none at all in the normalized state. The role of this retained austenite in temper embrittlement is discussed. In addition, cementite and not ϵ-carbide is the product of autotempering in the oil quenched state. A new feature of the so called 'granular bainite' was observed in the normalized state. This state consists of carbide-embedded bainite granules dispersed in a matrix of massive ferrite supersaturated with carbon. The full-annealed microstructure exhibits ferrite areas which were revealed as bainitic laths, and another part consisting of relatively thick cementite plates in another ferrite matrix. Such cementite is crystallographically oriented with respect to ferrite via the Bagaryatski relationship. (22 refs.)

109345 Proposed model for degradation of Gunn diodes as observed from study of the I-V characteristics. R.Gulati, I.Chandra, B.L.Sharma (Solid State Phys. Lab., Delhi, India).
Def. Sci. J. (India), vol.33, no.2, p.113-17 (April 1983). [received: Aug. 1983]
The effect of heat treatment on functional Gunn diodes has been investigated in the temperature range of 200-300°C. The influence of electric field during heat treatment has also been studied. The simple variations in I-V characteristics with annealing time have been utilized to interpret the contact behaviour. (8 refs.)

109346 An electron-microscopic examination of low-alloy steel fine structure after controlled rolling and direct quenching. V.I.Bolchakov, K.F.Starodubov (Acad. of Sci., Ukrainian SSR), I.V.Kuksenko.
Dopov. Akad. Nauk UkRSR. Ser. A (USSR), no.8, p.76-8 (1983). In Ukrainian.
Low carbon steel (alloyed by manganese with small additions of niobium and vanadium) quenched directly after controlled rolling is studied for mechanical properties and structure. The plates were water-quenched directly after controlled rolling at 800°C. The effect of quenching rate is also shown. Such a treatment permits yield strengths up to 800 MPa to be obtained under satisfactory impact strength. Mechanical properties of the steel after conventional controlled rolling are studied and presented for comparison. Fine structure of the steel was studied by means of transmission electron microscopy. (5 refs.)

109347 Influence of two-stage ageing on the spatial distribution of γ'-phase particles and on the mechanical properties of alloys with different elastic-distortion fields. E.V.Ugarova, N.T.Travina (Inst. of Metall. & Phys. of Metals, Moscow, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.134-8 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of Ni-Al-Cr alloys and of a refractory alloy EI661. A statistical analysis was made of electron micrographs obtained for alloys with different elastic-distortion fields. The relationships governing the formation of spatial distributions of particles after ageing in one and two stages were determined. The parameters of the spatial distribution of particles were compared with the mechanical properties of samples deformed by uniaxial tension. It was found that two-stage annealing was not suitable for improvement in the plasticity. The best properties were obtained when the average elastic distortions (strains) in the matrix were $\sim$0.2-0.5%. (4 refs.) *A.T.*

109348 Nature of new X-ray diffuse scattering effects in ageing Al-Zn alloys. E.T.Emirbekov, G.V.Kleshchev (Pedagogical Inst., Chelyabinsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.202-4 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
The number, shape, orientation, and size of diffuse scattering regions of a new type were determined. It was concluded that the various shapes of these regions represented superpositions of basic cylindrical regions and these were identified with microcavities $\sim$2.38 Å thick associated with the vacancy loops. It was therefore concluded that diffuse scattering of a new type, observed during the zone stage of precipitation represented scattering of X-rays by vacancy loops. (4 refs.) *A.T.*

109349 Thermal stabilisation of beryllium bronzes. N.Vasil'ev, Yu.A.Kaplun, Zh.P.Pastukhova.
Izv. VUZ Mashinostr. (USSR), no.7, p.140-3 (1983). In Russian.
A study is made of the thermal stabilisation of a beryllium bronze following strengthening ageing. Thermal stabilisation at 100-200°C is shown to cause a reduction in the level of residual stresses and an increase in the structural stability of the alloy. Thermal stabilisation under conditions in which the alloy is influenced by stresses generated by an external load causes a substantial rise in the elasticity limit and relaxation resistance of the alloy, thus permitting an improvement in the stability characteristics of the elastic components. (2 refs.) *L.M.H.*

109350 Effect of heat treatment temperature (HTT) on density, weight and volume of glass-like carbon (GC). B.N.Mehrotra, R.H.Bragg, A.S.Rao (Dept. of Materials Sci. & Mineral Engng., Univ. of California, Berkeley, CA, USA).
J. Mater. Sci. (GB), vol.18, no.9, p.2671-8 (Sept. 1983).
Room temperature measurements have been made of the density, weight and linear dimensions of glass-like carbon (GC) that was heat treated in the temperature range of 1000 to 2700°C for three hours in inert gas atmosphere. The density of GC decreased with increase in heat treatment temperature (HTT), reaching a maximum decrease of 12.4% at 2700°C; and the weight loss increased with increasing temperature to a maximum of about 1.9%. The volume increased and showed a quadratic dependence on the HTT, reaching a maximum value of about 10.2%. Subsequent application of hydrostatic pressures up to 1551 MPa (225000 psi) produced only a small increase in bulk density. It is concluded that the weight loss is not the major cause of the density decrease, instead the volume expansion of pores is mainly responsible for this behaviour. The weight loss is suggested to be due to the release of the last vestiges of hydrogen and the volume expansion is shown to be due to two different mechanisms operating in different temperature regimes. A gas pressure mechanism is predominant up to the HTT of 1600°C and at greater HTT thermal stress mechanism predominates. (32 refs.)

109351 The workability of molybdenum arc-melted with the group III transition metals. S.Morozumi (Res. Inst. for Iron, Steel & Other Metals, Tohoku Univ., Sendai, Japan), T.Komuro, S.Suzuki.
J. Jpn. Inst. Met. (Japan), vol.47, no.8, p.710-16 (Aug. 1983). In Japanese.
Compacts of molybdenum powder mixed with various amounts of holmium, lanthanum mischmetall, scandium and yttrium, were arc-melted under an argon atmosphere. Button-like ingots were chemically analyzed for carbon, oxygen and added elements in the ingots, tested for the warm workability, and examined by metallography. As it was found that scandium had an excellent effect on the workability of molybdenum, ingots melted with various amounts of scandium up to 0.5 percent were tested further for the workability and tensile properties at temperatures from 203 to 353K. (19 refs.)

109352 Heat treatment of the Cu-Ni-Sn alloys. P.Kratochvil, J.Mencl, M.Saxlova (Univ. Karlovy, Praha, Czechoslovakia).
Kovove Mater. (Czechoslovakia), vol.21, no.4, p.453-60 (1983). In Czech.
Supersaturated solid solution (Cu-9Ni)-Sn decomposes spinodally during appropriate annealing treatment. Spinodal decomposition predetermines the spacing and the degree of order of the (meta)stable precipitates that originate during prolonged annealing in the matrix. Alloys with 2, 4, 4.5 and 6 wt.%Sn annealed at 573K, 623K and 673K have been studied. Dependence of the proof stress R_p 0.2 and ductility A_5 on the time of annealing is presented. Microstructure development after precipitation annealing causes the increase of the proof stress and the simultaneous decrease of ductility. Results can be used in processing technology. (10 refs.)

109353 Further observations on the formation mechanisms of precipitate-free zones in an aged Al-16 wt pct Ag alloy. S.M.Merchant, M.R.Notis, D.B.Williams (Dept. of Metall. & Materials Engng., Lehigh Univ., Bethlehem, PA, USA).
Metall. Trans. A (USA), vol.14A, no.8, p.1745-8 (Aug. 1983).
It is shown that solute diffusion effects can adequately describe the presence of asymmetric solute concentration profiles and symmetric PFZ around grain boundaries in an aged Al-16 wt.% Ag alloy. These effects are also responsible for the lack of precipitate (γ') coarsening at the edge of the GPFZ and cause reprecipitation within the WPFZ formed during the initial conventional aging treatment. (10 refs.)

109354 Effect of electrothermal treatment on the carbide phase in die steel 8Kh4V2S2MF. A.S.Kholin, A.N.Chekhovoi, A.I.Abramov, V.B.Yakovlev.
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.798-800 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.38-40 (Nov. 1982).
The morphology of the carbide phase after electrothermal treatment and after conventional heat treatment with heating in a salt melt was investigated. The volumetric portion and size of the carbides were investigated under an electron microscope using statistical analysis. The carbide phase in complex-alloy die steel 8Kh4V2S2MF was appreciably broken up on increasing the temperature of electric heating for quenching from 1000 to 1200°C (a heating rate of 20 deg/sec in the region of the phase transformations). Electrothermal treatment ensured a finer carbide phase than heat treatment in accordance with the optimal regime with heating in a salt melt. (2 refs.)

109355 Effect of normalizing on the structure and properties of cast iron with spheroidal graphite for rolls. V.I.Vakula, S.I.Rudyuk, V.V.Korobeinik (Sci.-Res. Inst. of Metals, Kiev, Ukrainian SSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.801-5 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.41-4 (Nov. 1982).
In order to determine the efficiency of using high-temperature treatment and to develop optimum normalizing schedules a study was made of the effect of austenitizing conditions on the properties of high-strength cast iron (2.97% C; 1.44% Si; 0.54% Mn; 0.36% Cr; 0.85% Ni; 0.07% Mg; 0.03% P; 0.02% S) for section mill rolls of the design SShKhN48 (TU 14-2-158-74) with a barrel diameter and length of 320 and 800 mm, respectively. The properties of cast iron in the cast condition and after annealing at 650°C were determined for comparison. (8 refs.)

109356 Heat treatment and diamond burnishing of gray cast iron. L.A.Khvorostukhin, N.A.Bystrova, L.I.Belykh (Moscow Aviation Technol. Inst., Moscow, USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.805-7 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.44-5 (Nov. 1982).
Results are given of a study of the effect of burnishing schedules and heat treatment on elasticity and wear resistance of piston rings made of cast iron KhNV. Heat treatment was carried out by three schedules: (1) Oil quenching from 850°C+tempering at 350-600°C (in 50°C intervals) for 2 h. (2) Normalizing at 850°C. (3) Isothermal hardening with heating to 850°C and isothermal soaking for 2 h at 350°C. (4) The same with isothermal soaking for 2 h at 550°C. Burnishing was carried out at a load of $P_y=100$-300 N and a feed of 0.05 mm/rev for three passes ($i=3$) of a diamond tip with a radius of the spherical part $R_{sp}=2.0$ mm. (2 refs.)

109357 Change in structure and properties in stepped aging of V95 aluminum alloy plates. I.N.Firdlyander, V.S.Sandler, S.N.Borovskikh, I.I.Vlaskina.
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.811-14 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.49-52 (Nov. 1982).
It is concluded that stepped aging of V95 alloy, leading to a decrease in the yield strength of not less than 9-12% (T2 condition) and 15-20% (T3 condition) in comparison with the Tl condition, provides a change in corrosion characteristics of not less than $\sim$85 and 100%, respectively, of the possible change in these properties. A decrease in the hardening rate within the investigated limits leads to a decrease in the maximum of the tensile and yield strengths by 20-30 MPa and makes it possible to reduce the aging time until reaching the maximum in these characteristics by $\sim$2 h. In addition, the strength characteristics in overaging, the investigated corrosion characteristics, and the electrical resistance do not change but the character of precipitates in aging does change. (4 refs.)

109358 Twinning in heating of cast oxygen-free copper. E.I.Krupnikova-Perlina, V.G.Osintsev, V.A.Bliznyuk, A.F.Morozov (State Sci.-Res. & Design Inst. for Alloys & Treatment of Nonferrous Metals, USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.815-17 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.52-4 (Nov. 1982).
Investigates the structure of cast MOb 99.992-99.995% pure oxygen-free copper ($<5\times10^{-4}$ Sb, $<2\times10^{-4}$ As, $<4\times10^{-4}$ Mn, $<2.5\times10^{-3}$ Ni, $<2\times10^{-4}$ Sn, $<1\times10^{-4}$ Cr, $<5\times10^{-4}$ Pb, $<1\times10^{-4}$ Mg, $<5\times10^{-4}$ Si, $<1\times10^{-4}$ Bi, $<1\times10^{-3}$ Zn, $<1\times10^{-3}$ O, 1-3×10^{-4} Rem) and the character of its fracture in bending. The electrical conductivity of the copper at 20°C is 60 MS/m and the density 8.94×10^3 kg/m^3. The copper was melted and cast in a unit with a mixer under a layer of roasted charcoal in an atmosphere of generator gas. It is concluded that in the heating of cast oxygen-free copper to 300-600°C recrystallization occurs with the formation of acicular twins, which leads to the appearance of cracks in the copper ingots. (11 refs.)

109359 Changes in the properties of β brass having a shape-memory effect in the process of aging. T.V.Vozhdai, G.Z.Zatul'skii, V.K.Larin (Kiev Polytech. Inst., Kiev, Ukrainian SSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.824-7 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.59-61 (Nov. 1982).
It is concluded that the Cu 23.7% Zn 4.55% Al alloy has good technological and special properties after quenching. Prolonged aging of the alloy at 100° does not induce noticeable changes in the properties because of SME. With rising aging temperatures the initial and final temperatures of the reverse martensitic transformation drop, the initial deformation of the samples under constant stress decreases, and the deformation not removed during heating in the temperature range of the reverse martensitic transformation also increases. The effect of aging on the properties of β brass exhibiting SME is due to decomposition of martensite, which is responsible for the increase in stability in the course of prolonged operation at temperatures above 100°. (4 refs.)

109360 Determining distortion of steel structural materials. G.A.Adoyan, Yu.S.Aldoshin, A.M.Gerchikov, S.A.Shevchuk (Experimental Sci.-Res. Inst. of Machine Tools, USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.863-5 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.12, p.49-50 (Dec. 1982).
The described device makes it possible to determine under laboratory conditions the distortion of steel machine parts induced by relaxation of residual stresses. If a part made of steel 35 is distorted only due to relaxation of residual stresses at standard temperature then the distortion can be prevented by heating to low temperature ($\sim$100-150°C) for 3-4 h. When the sample is heated at successively higher temperatures and the distortion is determined after heating each time then the distortion decreasees noticeably in the temperature range of 200-350°C. (2 refs.)

109361 An investigation into the kinetics of migration of ferrite grain boundaries in a low-carbon steel during decarburisation. V.I.Movchan, N.A.Grudeva, N.V.Podobedova.
Russ. Metall. (GB), no.1, p.86-9 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.99-101 (1982).
An investigation of a low-carbon steel during the process of decarburisation allowed the calculation of the kinetics of boundary migration, an experimental determination of the kinetic coefficient expressed in the form of grain boundary diffusion and the determination of the activation energy for the process. (4 refs.)

109362 Thermodynamics and kinetics of steel decarburisation in annealing. Yu.M.Lakhtin, Ya.D.Kogan, G.A.Solodkin, E.Ya.Timoshenko.
Russ. Metall. (GB), no.1, p.101-5 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.115-19 (1982).
A thermodynamic assessment is given of the decarburising effect of nitriding atmospheres under different process conditions, which enables the compositions of atmospheres suppressing decarburisation during annealing to be predicted. Atmospheres of ammonia diluted by methane and 100%-cracked ammonia are considered. The influence of the composition of the atmosphere on the carbon potential is analysed. The composition of atmospheres preventing decarburisation during nitriding are calculated for various temperatures. A kinetic analysis is carried out of the change in decarburised-layer depth in relation to the process parameters. (4 refs.)

109363 Features of the formation of the $M_{23}C_6$ phase in pearlitic class steels during tempering. M.M.Sandomirskiy, T.V.Belyayeva, G.D.Pigrova.
Russ. Metall. (GB), no.1, p.108-11 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.123-6 (1982).
Repeated prolonged heating of pearlitic steels in the subcritical-temperature region, accompanied by acclerated cooling after each treatment cycle favours the occurrence of the carbide transformation with formation of the $M_{23}C_6$ phase. In chromium steels the $M_{23}C_6$ phase can be formed during tempering with chromium and iron present in roughly equal atom fractions, and even with somewhat smaller chromium contents. An elevated silicon content in pearlitic steel retards formation of $M_{23}C_6$ phase. A certain amount of silicon is dissolved in the $M_{23}C_6$ carbide phase formed during tempering of pearlitic steel. (13 refs.)

109364 Recrystallisation of Al-Sc alloys. M.E.Drits, L.S.Toropovam, Yu.G.Bykov, L.B.Ber, S.G.Pavlenko.
Russ. Metall. (GB), no.1, p.148-52 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.173-8 (1982).
The formation of anomalously supersaturated solutions with a higher concentration of scandium than the corresponding maximum solubility (about 0.4%) was detected in cast Al-Sc alloys. The temperature range of recrystallisation of Al-Sc alloys depends on the degree of dispersion of $ScAl_3$ particles in the starting deformed state and on changes in the degree of dispersion during recrystallisation heatings. During the heating of hardened alloys at temperatures 200-300°C decomposition occurs which hinders the recrystallisation. The high stability of the non-recrystallised structure of Al-Sc alloys is due to the formation on decomposition of the solid solution of fine spherical and uniformly distributed coherent particles of $ScAl_3$. (9 refs.)

109365 Relationships governing structure formation in the hot working of austenite in alloy steels. M.L.Bernshteyn, L.M.Kaputkina, S.D.Prokoshkin, S.V.Dobatkin.
Russ. Metall. (GB), no.2, p.82-90 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.94-104 (1982).
In hot working at strains of up to 7-10%, the austenite of the alloy steels is characterised by the development of rapid strain hardening which leads to the formation of a hot hardening structure, characterised by a higher density of dislocations distributed uniformly or a cellular-type substructure. An increase in strain (to ϵ_{max} which corresponds to the establishment of dynamic equilibrium between the hardening and softening processes) results in the development of softening (dynamic polygonisation), although hardening still predominates. Directional polygonal sub-boundaries appear and subgrains with a higher density of free dislocations form. An increase in strain (to ϵ_{max}) is accompanied by an increase in the volume fraction of the polygonised regions, the fraction of the equiaxed subgrains increases, the sub-boundaries are improved and the density of free dislocations decreases. On reaching strains slightly higher than ϵ_{max}, the steady state stage is characterised by the formation of a stable equiaxed polygonised substructure whose mean parameters remain constant during subsequent deformation changes and are controlled by repolygonisation. (24 refs.)

109366 Spontaneous recrystallisation of the steel matrix near non-metallic inclusions. S.I.Gubenko.
Russ. Metall. (GB), no.2, p.96-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.110-13 (1982).
Spontaneous steel-matrix recrystallisation due to non-metallic inclusions is local in character. The reason for its appearance are the volume effects arising in consequence of transformations in inclusions and leading to stress concentrations in the matrix and local plastic shear. The conditions for it to occur and the character of the structure produced depend on the temperature to which the steel is heated and those at which transformations occur in the inclusions, the heating or cooling rates and the magnitudes of the stresses arising in the transformations. These stresses, in their turn, are determined by the temperature and the difference in the packing density of the crystal lattices of the various inclusions or the modifications of one inclusion. Spontaneous recrystallisation of the matrix near inclusions can occur at the transformation temperature in the inclusion, or on subsequent heating, which affects the mechanism and rate of the recrystallisation. The effects considered occur during heating of steels before hot deformation or during heat treatment, and also during cooling after deformation or annealing, and promote formation of a heterogeneous steel structure. (no refs.)

109367 Structural changes and strengthening in strain aging of austenitic steel. V.R.Baraz, V.V.Pokachalov.
Russ. Metall. (GB), no.2, p.104-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.119-23 (1982).
Cold drawing of 13Kh18N10G3S2M2 steel produces intensive strain aging and is accompanied by partial decomposition of γ-solid solution. Post-deformation heating at 500 and 700°C reinforces this process. Aging at 500°C produces an additional increase in steel strength, the main increment being observed with brief holding (1 min) and explained by the occurrence of strain aging. At 700°C strength-loss, associated with depletion of the γ-solid solution, carbide-particle coagulation and the development of recovery and recrystallisation have a great influence. Aging at this temperature is characterised by anomalous growth of electrical resistivity, which is observed in the range in which primary recrystallisation occurs. This effect can be due to the increase in excess-vacancy concentration, and also matrix-grain refinement due to occurrence of primary recrystallisation. (7 refs.)

109368 Influence of temperature and the degree of deformation on the structure and properties of medium-carbon steel. A.A.Baranov, A.A.Minayev, V.P.Gorbatenko, I.N.Lad'yanov.
Russ. Metall. (GB), no.2, p.108-13 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.123-8 (1982).
High-temperature heating of 35 and 33GT steels promotes stabilisation of austenite, with a consequent retardation of its diffusion decomposition during cooling. Hot plastic deformation accelerates diffusion decomposition of supercooled austenite in the steels studied. The structure and properties of the steels investigated depends, in a complicated way, on the rolling temperature and deformation parameters. This is governed by the conditions under which the strengthening and strength-loss processes of hot-deformed austenite develop, and by the character of the structure and substructure formed in it. (4 refs.)

109369 Anomalous grain-size distributions during continuous grain growth. J.S.Distl, P.I.Welch, H.J.Bunge (Inst. fur Metallkunde und Metallphys., Tech. Univ. Clausthal, Clausthal, Germany).
Scr. Metall. (USA), vol.17, no.8, p.975-8 (Aug. 1983).
The texture and grain size distribution of solution treated and precipitation treated AlMn1 alloy after a final annealing treatment. The two peaks observed on the distribution curves are considered to be due to grains of the growing and disappearing texture components. (7 refs.)

109370 Effects of prior tempering on the strain aging of a continuously annealed 0.05% C dual phase steel. P.H.Chang (Res. Engng., Inland Steel Res. Labs., East Chicago, IN, USA).
Scr. Metall. (USA), vol.17, no.8, p.1009-14 (Aug. 1983).
The effect of different tempering treatments on the subsequent strain aging behavior of a 0.05% C plain carbon dual phase steel was studied. It was found that the strength (tensile and yield) of the strain aged specimens can be either increased or decreased. These results were explained in terms of the complex interplay of strain aging of ferrite, tempering of martensite and replacement of ϵ-carbides (if present) by cementite. For the 0.05% C dual phase steel, a 100°C tempering, even up to 1200 sec, does not stabilize ferrite

and martensite, consequently the subsequent strain aging resulted in significant martensite softening and replacement of ϵ-carbides by cementite. This led to an overall decrease in tensile strength and a negative dependence of yield strength increase ($\Delta\gamma$) on aging time. (9 refs.)

109371 Structural irregularities in solid $(Pb_{1-x}Sn_x)_{1-y}Te_y$ solutions after annealing in a temperature gradient. T.T.Dedegkaev, D.Kh.Lagkuev, V.A.Moshnikov, D.A.As'kov (A.F. Ioffe Physicotech. Inst., Acad. of Sci., Leningrad, USSR).
Sov. Phys.-Tech. Phys. (USA), vol.28, no.2, p.252-3 (Feb. 1983). Translation of: *Zh. Tekh. Fiz. (USSR)*, vol.53, no.2, p.404-6 (Feb. 1983). [received: Sept. 1983]
Microscopic irregularities in crystals cause a serious deterioration in the performance of devices using such crystals. In solid solutions of $(Pb_{1-x}Sn_x)_{1-y}Te_y$, there is a finite probability that microscopic inclusions will form whether the crystals are grown from a melt (due to concentration supercooling) or subjected to long-term isothermal annealing (due to retrograde behavior of the T-y state diagram). For this reason there is definite practical interest in investigating whether the microscopic uniformity of $(Pb_{1-x}Sn_x)_{1-y}Te_y$ solid solutions can be improved. The authors report experimental findings on how annealing in a temperature gradient affects the microscopic uniformity of undoped $(Pb_{1-x}Sn_x)_{1-y}.Te_y$ crystals containing an excess of tellurium. (4 refs.)

109372 Rapid isothermal annealing of Si implanted semi-insulating GaAs by means of high frequency induction heating. A.Cetronio, M.Bujatti, P.D'Eustacchio, S.Ciceroni (Res. Labs., Selenia SpA, Rome, Italy).
Laser-Solid Interactions and Transient Thermal Processing of Materials, Boston, MA, USA, 1-4 Nov. 1982 (New York, USA: Elsevier 1983), p.641-6
Experimental results obtained by rapid isothermal annealing of Si implanted semi-insulating GaAs are presented and compared with results obtained by electron-beam and conventional furnace annealing. For high Cr-doped material, the problem of redistribution cannot be avoided, and for undoped material, this technique yields very good activation (near 100%) and high mobility (approximately 4400 $cm^2/V.sec$). (7 refs.)

109373 Thermal pulse annealing of $Hg_{1-x}Cd_xTe$. K.C.Dimiduk, W.G.Opyd, M.E.Greiner, J.F.Gibbons, T.W.Sigmon (Stanford Electronics Labs., Stanford, CA, USA).
Laser-Solid Interactions and Transient Thermal Processing of Materials, Boston, MA, USA, 1-4 Nov. 1982 (New York, USA: Elsevier 1983), p.671-6
Thermal pulse annealing has been used to modify the near surface of $Hg_{1-x}Cd_xTe$. Using anneals of approximately 260°C for seven seconds, the crystal quality of epitaxial HgCdTe surfaces can be improved as observed by MeV He^+ ion channeling. Similar anneals have also been used to repair the damage resulting from a 250 keV, 10^{15} $^{11}B/cm^2$ implant into HgCdTe held at LN_2. For higher temperatures and/or longer anneals, surface Hg loss is observed. Rutherford back-scattering measurements are used to measure this loss. The resulting loss rate data is described by $N_{\square}=A \exp(-\Delta E/kT)$ where A and ΔE depend on the material composition with $A=10^{29}$, $\Delta E=1.8$ eV and $A=10^{36}$, $\Delta E=2.6$ eV for $x=0.23$ and 0.4, respectively. (7 refs.)

109374 New quenching experiments with high purity and carbon doped iron. H.Wever (Inst. fur Metallforschung, Tech. Univ., Berlin, Germany), O.Seydel, G.Frohberg.
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.512-15
In α-Fe with C- and N-contents below 1 at.ppm a recovery stage is observed between 380 and 600K which can be associated with the annealing of vacancies, partly via C-vacancy-pairs. In C-doped α-Fe there are different precipitation characteristics of ϵ-carbide according to three different ranges of quenching rates. (10 refs.)

109375 Quenching and annealing experiments on high-purity iron with and without carbon. S.Takaki (Res. Inst. for Iron, Steel & Other Metals, Tohoku Univ., Sendai, Japan), H.Schultz, H.Kimura.
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.516-19
The first successful repeated quenching and slow cooling experiment with one specimen was performed with a high-purity iron. High purity iron specimens doped with small amounts of carbon were quenched and isochronally annealed in ultra-high vacuum to minimize contamination during heating. The rate and the fraction of recovery of the quenched-in resistivity are much smaller in specimens with about 20 at.ppm carbon than in specimens with more than 100 at.ppm carbon. The recovery characteristics of the undoped high-purity iron is similar to that in specimens with about 20 at.ppm carbon. At present, the authors cannot separate the effect of quenched-in vacancies from that of carbon. (13 refs.)

81.40J Elasticity and anelasticity

(see also 62.20D Elastic constants, 62.40 Anelasticity, internal friction, and mechanical resonances)

109376 Size effects and micromechanics of a porous solid. R.S.Lakes (Div. of Materials Engng., Coll. of Engng., Univ. of Iowa, Iowa City, IA, USA).
J. Mater. Sci. (GB), vol.18, no.9, p.2572-80 (Sept. 1983).
The rigidity of rods of a polymeric foam in bending and torsion is measured as a function of diameter. The dependence of rigidity upon specimen size is found to be inconsistent with a classically viscoelastic continuum model. The Cosserat continuum, which admits additional degrees of freedom associated with rotation of the microstructure, describes the foam more accurately than the classical continuum. Evidence is presented that additional degrees of freedom, associated with the deformation of the microstructure, must be incorporated in a complete continuum model of foamed materials. (28 refs.)

109377 Young's modulus of Fe-, Co-, Pd- and Pt-based amorphous wires produced by the in-rotating-water spinning method. A.Inoue, H.S.Chen, J.T.Krause, T.Masumoto, M.Hagiwara (Bell Labs., Murray Hill, NJ, USA).
J. Mater. Sci. (GB), vol.18, no.9, p.2743-51 (Sept. 1983).
Presents the Young's modulus of $Fe_{100-x-y}Si_xB_y$, $Fe_{100-x-y}P_xC_y$, $Co_{100-x-y}Si_xB_y$, $Pd_{77.5}Cu_6Si_{16.5}$, $Pd_{48}Ni_{32}P_{20}$ and $Pt_{60}Ni_{15}P_{25}$ amorphous wires determined from the Young's modulus sound velocity measurement. With increasing metalloid content, the Young's modulus increases from 1.58×10^{11} to 1.87×10^{11} N m^{-2} for Fe-Si-B, from 1.40×10^{11} to 1.52×10^{11} N m^{-2} for Fe-P-C and from 1.73×10^{11} to 1.75×10^{11} N m^{-2} for Co-Si-B systems. The increase in Young's modulus with the amount of metalloid elements is the largest for B, followed by Si, C and then P. The Young's modulus of Fe and Co-Si-B amorphous wires increases significantly with the replacement of iron or cobalt by IV-VII group transition metals. It was recognized that there existed a strong correlation between Young's modulus (E) and tensile fracture strength (σ_f); the ratio of σ_f to E is approximated to be 0.02 for all the amorphous wires investigated. These results imply that the Young's modulus is dominated mainly by the structural and compositional short-range orderings due to the strong interaction between metal and metalloid atoms which hinders the internal displacements. (31 refs.)

109378 Internal friction in 3NiCrMoV steel. J.Jurek, J.Krumpos, Z.Trojanova, P.Lukac (Katedra Fyziky Kovu Matematicko-Fyzikalni Fakulta UK, Praha, Czechoslovakia).
Kovove Mater. (Czechoslovakia), vol.21, no.4, p.439-44 (1983). In Czech.
Two peaks of internal stress in 3NiCrMoV steel samples are observed at 160K and at temperatures between 230 and 250K. The temperature of the first peak is independent of most experimental conditions. The position and height of the second peak depends on thermal working of the material. Interaction between dislocations and carbon and nitrogen interstitials seems to be responsible for these two peaks. (15 refs.)

109379 Dynamic mechanical properties of a polycarbonate/polystyrene copolymer: effects of casting solvent. G.C.Eastmond, K.Haraguchi (Donnan Labs., Univ. of Liverpool, Liverpool, England).
Polymer (GB), vol.24, no.9, p.1171-9 (Sept. 1983).
Dynamic mechanical properties of three polycarbonates, of polystyrene and of a blend and a copolymer of polystyrene with one polycarbonate have been investigated. While the properties of the blend were found to be a simple combination of those of the constituent homopolymers, modified α-relaxation behaviour was found for the polystyrene chains in the copolymer. The modifications, dependent on the casting solvent and thermal treatments used in sample preparation, were found to correspond to enhancement of the segmental motions in polystyrene chains, in spite of their attachment to more rigid polycarbonate. The modifications have been attributed to incorporation of excess free volume during solvent casting. A mechanism is proposed which correlates the excess free-volume fractions with the solubility parameters of the casting solvents. (30 refs.)

109380 Examination of the structure, magnetic and elastic properties of single crystals of alloy Fe-25% Co-30% Cr-3.4% Mo. A.E.Kolchin, B.G.Livshits, I.B.Sidorova.
Russ. Metall. (GB), no.3, p.95-7 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.3, p.110-13 (1982).
Crystals of alloy Fe-25% Co-30% Cr-3.4% Mo are elastically anisotropic with the anisotropy factor. A considerably larger than one at the temperature of isothermal thermomagnetic treatment. It was confirmed that in this alloy there are significant relative differences in the lattice parameters of the phases after both the final optimum heat treatment and the isothermal thermomagnetic treatment. The microstructure which determines the optimum magnetic properties of the alloy is obtained if the magnetic field during isothermal thermomagnetic treatment is in the (100) direction. Deviation from this direction causes the a_1 ferromagnetic phase to emerge oriented with its longitudinal axes or the axes of several particles in the direction intermediate between the direction of the magnetic field and (100). (8 refs.)

109381 Mechanical relaxation effects of self-interstitial-atoms in molybdenum. H.Jacques, K.-H.Robrock (Inst. fur Festkorperforschung, KFA Julich, Julich, Germany).
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.159-62
Careful elastic after effect measurements have been performed in Mo after electron irradiation at 5K and after isochronal annealing in search for a reorientation process of ⟨110⟩-dumbbell self-interstitial-atoms. It was found, that this process does not occur, neither as a rotation in place nor during the free migration of the ⟨110⟩-dumbbells. It is proposed to attribute this observation to a two dimensional migration of the ⟨110⟩-dumbbell during which the orientation of the dumbbell axis is conserved. This particular jump explains also the complex behaviour of resistivity recovery observed in earlier studies. (10 refs.)

109382 Elastic modulus change in Mo due to Frenkel defects. S.Okuda, H.Mizubayashi (Inst. of Materials Sci., Univ. of Tsukuba, Ibaraki, Japan).
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.163-6
Diaelastic polarization of self-interstitial atom (SIA) in Mo and Ag was studied by measurements of elastic modulus change after fast neutron irradiation at about 5K. The modulus changes per unit concentration of the defects due to this effect were obtained as follows: For Mo, $-\Delta E\langle100\rangle/cE\langle100\rangle\simeq56\sim24$, and $-\Delta E\langle111\rangle/cE\langle111\rangle\simeq18\sim12$. For Ag, $-\Delta E\langle100\rangle/cE\langle100\rangle\simeq45$ and $-\Delta E\langle111\rangle/cE\langle111\rangle\simeq45$. These values mean that $-\Delta C_{44}\langle-\Delta C'$ for Mo and $-\Delta C_{44}\rangle-\Delta C'$ for Ag. The results are in agreement with the model of ⟨110⟩ split SIA in Mo and of ⟨100⟩ split SIA in Ag. (11 refs.)

109383 Interstitial interaction in W observed by relaxation measurements. H.Mizubayashi, S.Okuda, T.Arai (Inst. of Materials Sci., Univ. of Tsukuba, Ibaraki, Japan).
Point Defects and Defect Interactions in Metals. Proceedings of the Yamada Conference V, Kyoto, Japan, 16-20 Nov. 1981 (Amsterdam, Netherlands: North-Holland 1982), p.167-70
In previous experiments, the relaxation peak due to rotational motion without migration of ⟨110⟩-split type self-interstitials in neutron irradiated W was observed at 5.5K ($\tau\simeq2$min) and at 8K ($f\simeq500$ Hz), and it showed the strong deviation from the $1/T$ law in its relaxation strength. Here, this deviation from the $1/T$ law is studied from the view point of interstitial interactions. (8 refs.)

109384 Determination of minimum bending radii for bending of round wires and bars. R.Kopp, W.Knott (Inst. fur Bildsame Formgebung, Rheinisch-Westfalischen Tech. Hochschule Aachen, Aachen, Germany).
Arch. Eisenhuettenwes. (Germany), vol.54, no.7, p.277-84 (July 1983). In German.
Describes the crack testing method applied and gives the derivation of the equations for the minimum bending radius. The correlations between minimum bending radius, yield point, tensile strength, yield point/tensile strength ratio and hardness of various steel grades are discussed. A simple correlation between minimum bending radius and percentage reduction of area after fracture is developed. A discussion of this correlation on the basis of viscoplastic results is presented. (no refs.)

109385 Extension of the notion of foundry alloy accommodation limit. J.Boutault, C.Fromont, E.Plenard.
Fonderie - Fondeur d'Ajourd'hui (France), no.26, p.31-42 (June-July 1983). In French.
The authors describe the different means of determining the accommodation limit. They discuss the practical value of a complementary and new notion making it possible to guarantee a casting to be both accommodated and have a total deformation smaller than a threshold acceptable for a given use in mechanics. (3 refs.)

109386 Extended ductility in Al-Zn-Mg alloys. V.D.Kodgire, A.M.Rao, A.K.Mallik (Indian Inst. of Technol., Bombay, India).
Trans. Indian Inst. Met., vol.35, no.5, p.443-7 (Oct. 1982). [received: Aug. 1983]
High temperature uniaxial deformation behaviour of Al-6Zn-1Mg and Al-6Zn-2.3Mg alloys with small additions of titanium was investigated. The alloys were suitably processed to give final grain sizes of 24 and 20 μm, respectively. Tensile tests on strip samples using a screw driven machine were conducted over a temperature range of 673-773K (400-500°C) and at strain rates between 1.11×10^{-4} to 2.2×10^{-2}. A sigmoidal relationship between the

flow stress and strain rate was observed. Measurement of the strain rate sensitivity index as a function of strain rate and temperature showed good correlation with total elongation obtained. The maximum elongations obtained under constant crosshead velocity testing were ~80% and 120% respectively for the two alloys. Cavitation, which was observed at the grain boundaries increased with increasing strain and temperature but decreasing strain rate. Failure was associated with the growth and interlinkage of the cavities. (19 refs.)

109387 Deformation studies on Al-Mg-Zr alloy. J.Mukhopadhyay, A.M.Rao, A.K.Mallik (Indian Inst. of Technol., Bombay, India).
Trans. Indian Inst. Met., vol.35, no.5, p.451-5 (Oct. 1982). [received: Aug. 1983]
Al-Mg alloys are reported to be superplastic. The aim of the present investigation was to study the deformation behaviour of Al-5% Mg alloy with a small addition of zirconium (0.3%) as grain refiner. Grain size of about 26 μm was produced by an appropriate thermomechanical treatment. Investigations were carried out under uniaxial and biaxial state of stress over wide ranges of temperature and strain rate. The optimal temperature and strain rate for obtaining maximum elongation (~92%) were determined to be 573K (300°C) and 1.4×10^{-3} S^{-1} respectively. High temperature 573K (300°C) forming limit diagram shows that the limiting strain at this temperature increases three fold compared to that obtainable at room temperature. (15 refs.)

109388 On the role of Bauschinger effect in tensile tests following torsional prestrain. M.K.Rao (School of Engng., Univ. of Pittsburgh, Pittsburgh, PA, USA), G.S.Murty.
Trans. Indian Inst. Met., vol.35, no.6, p.543-7 (Dec. 1982). [received: Aug. 1983]
A comparative study of the (i) torsional prestrain effect on the subsequent tensile behavior and (ii) tensile prestrain effect on the subsequent compressive behavior has been made on mild steel, copper and aluminum with a view to assess the role of Bauschinger effect in explaining the observed region of high strain hardening rate in tension following torsional prestrain. While the lowering of flow stress due to change in the mode of testing from torsion to tension is less than that in tension-compression tests, the initial strain hardening rate in the former type of test is significantly higher than that due to stress reversal in tension-compression tests. These results are incompatible with the interpretation that the region of high strain hardening rate in tension following torsional prestrain is a consequence of Bauschinger effect. (5 refs.)

109389 Microstructure-property correlation in alloy Ti-6.5Al-3.3Mo-1.6Zr-0.3Si. D.Mukherjee, D.Banerjee, R.L.Saha (Defence Metall. Res. Lab., Hyderabad, India).
Trans. Indian Inst. Met., vol.35, no.6, p.583-94 (Dec. 1982). [received: Aug. 1983]
Ti-6.5Al-3.3Mo-1.6Zr-0.3Si is a $\alpha+\beta$ titanium alloy with good creep properties. A wide variety of microstructures were developed in this alloy through heat treatment in the $\alpha+\beta$ and β region following $\alpha+\beta$ processing. The prior β grain size in β- heat treated samples and the primary α volume fraction in $\alpha+\beta$ heat treated samples was characterised quantitatively. Tensile and creep rupture data were obtained for the nine microstructure generated and fracture surfaces of the tensile tested samples examined by SEM. The results indicate that β_{-} heat treated samples possess superior creep properties but somewhat poorer tensile ductility than $\alpha+\beta$ heat treated samples. The yield strength decreases with cooling rate from heat treatment temperatures for both $\alpha+\beta$ and β treated samples. The property variation with microstructure can be explained with the existing understanding of the effect of microstructure on properties in titanium alloys. (7 refs.)

109390 Plastic deformation behavior of mild steel along spiral strain trajectory. Y.Ohashi, E.Tanaka, T.Ueno (Dept. of Mech. Engng., Nagoya Univ., Nagoya, Japan).
Mech. Mater. (Netherlands), vol.2, no.2, p.111-22 (Aug. 1983).
An experiment was performed on the deformation of mild steel along a series of three-dimensional bilinear strain trajectories with each of 18 kinds of spiral part consisting of various combinations of constant curvatures and torsions of strain trajectory. Combined loadings of axial force, torque and internal pressure were applied to thin-walled tubular specimens of initially isotropic material by means of an automatic combined loading testing machine. The hypothesis of local determinability is discussed and its practical usefulness is examined in light of the experimental results. A simple constitutive relation is established by means of the hypothesis and its accuracy is discussed. (12 refs.)

109391 Influence of dislocation density on microchemical inhomogeneity of the thermal influence zone of welded Nb alloys. E.A.Asnic, R.I.Barabash, O.V.Bilots'kii, M.M.Nerodenko, O.V.Polenur.
Dopov. Akad. Nauk UkRSR. Ser. A (USSR), no.5, p.75-8 (1983). In Ukrainian.
Plastic deformation of the heat-affected zone in the process of niobium alloy welding increases dislocation density in this zone and concentration of interstitial impurities (nitrogen and oxygen). An increase of impurity concentration may induce failure in this zone. (9 refs.)

109392 Interrelationship between twinning and slip in single crystals of heterophase alloys with a low energy of stacking faults. Yu.I.Chumlyakov, V.F.Esipenko, L.S.Bushnev, A.D.Korotaev (V.D. Kuznetsov Siberian Physicotech. Sci.-Res. Inst., State Univ., Tomsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.171-8 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
Crystals of the Cu-12% Al-2.3% Co (at.%) alloy with a specific orientation were hardened by particles of noncoherent phases. The mechanism of plastic deformation was studied as a function of the dispersion of the particles. Critical parameters of the dispersion, ensuring twinning beginning directly from the yield stress, were found. When the particle size was increased, the conditions for a change in the plastic deformation mechanism from slip to twinning were attained during slip. A model was developed to describe the change in the plastic deformation, which preceded twinning, as a function of the energy of stacking faults in the matrix and as a function of dispersion of the particles. The predictions of the model were checked experimentally. (19 refs.) *A.T.*

109393 Strength and plasticity of two-phase ferrite martensitic steels. B.M.Bronfin, M.I.Gol'dshtein, A.A.Emel'yanov, A.Z.Shifman, V.P.Shveikin (S.M. Kirov Ural Polytech. Inst., Sverdlovsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.179-85 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
A study was made of the influence of microstructure parameters on the strength and plasticity of low-carbon two-phase steels with the ferrite martensitic structure. Relationships were obtained for the time dependence of the breaking strength and for the uniform elongation as a function of the ferrite grain size and of the volume fraction of martensite in the steel structure. Nomograms were constructured for the prediction of the ferrite grain size and of the amount of martensite in a structure of a steel needed to achieve specified values of the strength and uniform elongation. (13 refs.) *A.T.*

109394 The effect of superconducting transition on slipping and twinning in indium and its alloys. I.N.Kuz'menko, S.V.Lubenets, V.V.Pustovalov, L.S.Fomenko.
Fiz. Nizk. Temp. (USSR), vol.9, no.8, p.865-72 (Aug. 1983). In Russian. English translation in: *Sov. J. Low Temp. Phys. (USA)*
Single crystals of pure indium and In-Pb alloys (6 and 8 at.%Pb) are tested for compression with the constant rate $\dot{\epsilon}=10^{-5}\div10^{-4}$ sec^{-1} at temperatures 0.48 and 1.7K, and the effect of sample state on yield point and twinning stress as well as the effect of *N-S* transition on flow stress under slip and twinning are considered. The effect of an electron subsystem state on the parameters of plastic strain under slip (monotone or jump-like) is found to be appreciable. For the In-Pb alloys which up to $\epsilon=6\%$ are deformed only due to twinning, neither twinning stress nor flow stress is dependent on sample state. (12 refs.)

109395 High temperature ductility of iron and some steels. C.J.Rosa (Dept. of Materials Sci., Univ. of Cincinnati, Cincinnati, OH, USA).
High Temp. Sci. (USA), vol.16, no.2, p.69-81 (April 1983). [received: Sept. 1983]
Hot-torsion results, from C-Mn steels and low-C alloy steels, obtained under a shear strain rate of 11.8 s^{-1} indicate that the optimum hot-ductility temperature range lies between 1500 and 1550K. It is shown that the evaluated surface shear stress varies linearly from 66 to 39 MPa with increasing temperature from 1339 to 1477K. These data are useful for rotary piercing of billets in the production of seamless pipes. (20 refs.)

109396 Effect of swaging on the 1000°C compressive slow plastic flow characteristics of the directionally solidified eutectic alloy γ/γ'-α. J.Daniel Whittenberger (NASA, Lewis Res. Center, Cleveland, OH, USA), G.Wirth.
J. Mater. Sci. (GB), vol.18, no.9, p.2581-8 (Sept. 1983).
Swaging between 750 and 1050°C has been investigated as a means to introduce work into the directionally solidified eutectic alloy γ/γ'-α (Ni-32.3 wt.%Mo-6.3 wt.%Al) and increase the elevated temperature creep strength. The 1000°C slow plastic compressive flow stress-strain rate properties in air of as-grown, annealed, and worked nominally 10 and 25% materials have been determined. Swaging did not improve the slow plastic behaviour. In fact large reductions tended to degrade the strength and produced a change in the deformation mechanism from uniform flow to one involving intense slip band formation. Comparison of 1000°C tensile and compressive strength-strain rate data reveals that deformation is independent of the stress state. (12 refs.)

109397 Effect of intercritical quenching on microstructure and tensile properties of steels 15 and 15Mn2Nb. D.-Z.Yang, X.-W.Sun, T.-C.Lei (Dept. of Metals & Technol., Harbin Inst. of Technol., Harbin, China).
J. Mater. Sci. (GB), vol.18, no.9, p.2727-31 (Sept. 1983).
The microstructure and tensile properties of steels 15 and 15Mn2Nb after quenching from intercritical ($\gamma+\alpha$) temperatures were studied. It was shown that steel 15 has an 'island-type' dual-phase structure (ferrite plus martensite) after intercritical quenching, while the steel 15Mn2Nb has the 'lamellar' structure with alternatively arranged ferrite and martensite needles. Such a lamellar dual-phase structure obviously has improved strength and ductility and is suggested as one of the effective methods in developing high strength dual-phase steels. (4 refs.)

109398 An experimental study of the effect of prestressed loose carbon strands on composite strength. Zhifan Chi (Northwestern Polytech. Univ., China), Tsu-Wei Chou.
J. Compos. Mater. (USA), vol.17, no.3, p.196-209 (May 1983).
The strength behavior of composites reinforced with prestressed fiber strands is determined. A theoretical analysis of the feasibility of strength enhancement by fiber prestressing has been demonstrated previously (see ibid., vol.17, p.26, 1983). Fiber prestressing is achieved by bending of the loose bundles and the weak points of the fibers are thus eliminated. The experimental results show that after prebending the fibers to an appropriate level the strength of composites can be enhanced. Although the increase in composite mean strength is small, the variation of composite strength is greatly reduced, and the strength at high survivability level is enhanced most significantly. (6 refs.)

109399 On the mechanical properties of the heat treated and cold drawn low carbon steel wire. Won Tae Kim (Seoul Nat. Univ., Seoul, Korea), Tong Hoon Kim.
J. Korean Inst. Met., vol.21, no.5, p.482-8 (May 1983). In Korean.
Tensile test and microstructural analysis were performed to investigate the effects of dual phase heat treatment and cold drawing so as to promote the mechanical properties of 0.07% C steel wire. The strength of the dual phase steel wires varied with volume fraction, shape and size of martensite and grain size of ferrite. The strength of the dual phase steel wire was approximately proportional to a reciprocal of square root of mean free path. The elongation of dual phase steel wires varied with volume fraction, distribution, and size of martensite. The carbon content in martensite changed the strength of martensite, which affected the elongation of the specimens. Low carbon steel wire of 1257 MPa in tensile strength and 4 percent in elongation was obtained, when low carbon steel rod with 475 MPa and 38% in tensile strength and elongation, respectively, was heat treated and cold drawn. (13 refs.)

109400 Cyclic stress-strain behaviors of carbon steel and Cr-Mo steel. K.Kanazawa, K.Yamaguchi, K.Kobayashi (Nat. Res. Inst. for Metals, Tokyo, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.605-9 (June 1983). In Japanese.
Cyclic stress-strain curves were obtained by the incremental step method for a carbon steel SB 49 and a chromium-molybdenum steel SCMV 4. The temperature and strain rate dependences of the cyclic stress-strain curves were discussed and the curves were compared with those obtained by the companion specimens method. Cyclic hardening and cyclic softening behaviors were observed for SB 49 and SCMV 4, respectively. The cyclic stress-strain curve lay at the higher stress level side than the monotonic stress-strain curve for SB49; for SCMV 4 it was the other way. The cyclic stress-strain curve depended on strain rate. With decreasing strain rate, the stress amplitude for SB49 increased at 200 and 300°C, but decreased at 400 and 500°C. Similar dependences were observed in SCMV 4 steel. The cyclic stress-strain curve can be expressed very well by the experimental equation as $\Delta\epsilon_T/2=(\Delta\sigma/2)/E'+\{(\Delta\sigma/2)/K'\}^{1/n'}$. (9 refs.)

109401 Study on elastic-plastic deformation analysis using a cyclic stress-strain curve. T.Igari, K.Setoguchi, M.Yamauchi (Nagasaki Tech. Inst., Mitsubishi Heavy Industries, Ltd., Nagasaki, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.610-14 (June 1983). In Japanese.
Presents the results of the elastic-plastic deformation analysis using a cyclic stress-strain curve with an intention to apply this method for predicting the

low-cycle fatigue life. Uniaxial plastic cycling tests were performed on $2^1/_4$Cr-1Mo steel to investigate the correspondence between the cyclic stress-strain curve and the hysteresis loop, and also to determine what mathematical model should be used for analysis of deformation at stress reversal. Furthermore, a cyclic in-plane bending test was performed on a flat plate to clarify the validity of the cyclic stress-strain curve-based theoretical analysis. The cyclic stress-strain curve corresponds nearly to the ascending curve of hysteresis loop scaled by a factor of $^1/_2$ for both stress and strain. Therefore, the cyclic stress-strain curve can be determined from the shape of hysteresis loop, for simplicity. (7 refs.)

109402 Effects of V-addition and welding method on the change of microstructure during creep process for 308 type stainless weld metals. T.Zaizen, Y.Otoguro, S.Aoki, K.Suzuki, S.Bando (Products Res. & Dev. Labs., Nippon Steel Co., Sagamihara, Japan).

J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.625-9 (June 1983). In Japanese.

The microstructure and the fractography were determined by transmission and scanning electron microscopies on Tp 308 and Tp 308-V stainless steel weld metals made by GTAW and SAW methods. In the early stage of the creep process, dislocations are multiplied in austenite and locked by fine precipitates formed in austenite. Besides, the precipitates formed in δ derrite grow up to 0.05μ diameter. The formation of cell structure in austenite and the growth of precipitates in δ ferrite proceed during the creep process. (4 refs.)

109403 Transient creep in iron at low stresses and homologous temperatures 0.40-0.54. J.Novotny, J.Fiala, J.Cadek (CSAV, Brno, Czechoslovakia).

Kovove Mater. (Czechoslovakia), vol.21, no.4, p.397-411 (1983). In Czech.

Transient creep of high purity iron at low stresses (0.1 to 3.5 MPa) and at homologous temperatures 0.40 to 0.54 was investigated using the technique of helicoid specimens. At intercept grain sizes less than $\sim 123\ \mu m$ (Region 1), at which Coble creep operates, the transient creep strain increases with increasing applied stress linearly and with temperature monotonously. The transient creep period length t_t does not depend on applied stress and increases exponentially with decreasing temperature. The transient creep strain is caused primarily by the bowing-out of links of the three dimensional dislocation network and by the release and motion of some of these links. The relative importance of the second of these processes increases with temperature. The climb of the links is most probably dislocation core diffusion controlled. At intercept grain sizes greater than $\sim 123\ \mu m$ (Region 2), at which Harper-Dorn creep operates, the transient creep strain ϵ_t increases with applied stress linearly; however, the influence of testing temperature is eventually overlapped by the effects of mechanical and thermal treatment before the creep exposure. This applies to transient creep period length t_t as well. The same processes as in Region 1 were suggested to be responsible for transient creep in Region 2. (23 refs.)

109404 High temperature creep in a Cu-2%Fe alloy. K.Kucharova, F.Dobes, A.Orlova, K.Milicka, J.Cadek (SAV, Brno, Czechoslovakia).

Kovove Mater. (Czechoslovakia), vol.21, no.4, p.412-24 (1983). In Czech.

Results of an investigation of creep in Cu-2wt.%Fe alloy strengthened by coherent gamma-iron particles in a temperature and stress region of 673 to 873K and 10-95 MPa, respectively, are presented and discussed. The discussion leads to the conclusion that, most probably, at very low stresses, the Coble diffusion deformation mechanism associated with a threshold stress dominates. As another possible mechanism controlling the steady state creep rate in the whole investigated region of experimental conditions, the thermally activated cutting of gamma-iron particles dependent on the creation of an interface boundary was suggested. (25 refs.)

109405 Variations in density of movable dislocations in the zone of microplastic strain. S.A.Golovin, D.M.Levin (Tulsky Polytech. Inst., Tula, USSR), A.Puskar.

Kovove Mater. (Czechoslovakia), vol.21, no.4, p.445-52 (1983). In Slovak.

The measurement of internal damping for gradual increase of strain amplitude $\delta(\uparrow\gamma)$ and following gradual decrease of strain amplitude $\delta(\downarrow\gamma)$ after reaching selected limit values γ_m made it possible for the authors to determine their difference which is the result of energy scatter on the dislocations which were formed during gradual increase of γ up to the value γ_m. The experiments performed with Cu-9.2 at.% Al and Cu-13.8 at.%Al alloys have shown that with the increase of γ_m $\Delta\delta$ also increases which is connected with the increase in the density of 'fresh' dislocations ρ_p in the material. The experimental results obtained can be processed by the use of the model developed by Golovin and Levin (1982). On the basis of the analysis it can be concluded that in the initial stage of microplasticity $\rho_p \sim \gamma_p{}^3$ and during its following $\rho_p \sim \gamma_p{}^{3/2}$, up to the start of microplastic strain, i.e. up to reaching the yield point of material. (20 refs.)

109406 Control of superplastic cavitation by hydrostatic pressure. C.C.Bampton, M.W.Mahoney, C.H.Hamilton, A.K.Ghosh (Rockwell Internat. Sci. Center, Thousand Oaks, CA, USA), R.Raj.

Metall. Trans. A (USA), vol.14A, no.8, p.1583-91 (Aug. 1983).

It has been shown that the application of hydrostatic gas pressures during superplastic deformation of fine grained 7475 Al can entirely prevent the intergranular cavitation normally encountered at atmospheric pressure. A critical ratio of hydrostatic pressure to flow stress may be defined for each superplastic forming condition above which virtually no cavitation occurs. In superplastic deformation conditions where intergranular cavitation plays a significant part in final tensile rupture, the superplastic ductility may be improved by the application of hydrostatic pressures. Similarly, detrimental effects of large superplastic strains on service properties may be reduced or elimited by the application of suitable hydrostatic pressures during superplastic forming. In this case, superplastically formed mateiral may have the same design allowables as conventional 7475 Al sheet. (14 refs.)

109407 Development of forming limits for superplastic formed fine grain 7475 Al. M.W.Mahoney, C.H.Hamilton, A.K.Ghosh (Rockwell Internat. Sci. Center, Thousand Oaks, CA, USA).

Metall. Trans. A (USA), vol.14A, no.8, p.1593-8 (Aug. 1983).

Forming limits in conventional sheet metal forming are given by strain levels obtainable prior to the onset of a localized neck or tear in the sheet. While the external appearance of such a neck is not observed in superplastic metals until strains become quite large, the formation of internal cavities could dictate the tolerable levels of strain in formed components. These useful strain limits for a superplastic 7475 Al alloy have been explored. The approach used was to establish the influence of strain state (uniaxial, plane strain, and balanced biaxial) on the inception and growth characteristics of cavities and to correlate the extent of cavitation with material properties. Based on these data, it was then possible to establish strain states for which little or no loss in properties was observed, and thereby to define forming limits for superplastic forming this material. These results, coupled with comparisons against strains developed in actual parts as well as analytically predicted strains, show that a wide range of structural parts can be superplastically formed within the constraints of the recommended forming limits. (15 refs.)

109408 Deformation processing of an aluminium alloy containing particles: studies on Al-5 pct Si alloy 4043. K.P.Rao (Dept. of Metallurgy, Indian Inst. of Technol., Madras, India), S.M.Doraivelu, H.M.Roshan, Y.V.R.K.Prasad.

Metall. Trans. A (USA), vol.14A, no.8, p.1671-9 (Aug. 1983).

Al-5 wt.% Si alloy is processed by upset forging in the temperature range 300K to 800K and in the strain rate range 0.02 to 200 s^{-1}. The hardness and tensile properties of the product have been studied. A 'safe' window in the strain rate-temperature field has been identified for processing of this alloy to obtain maximum tensile ductility in the product. For the above strain rate range, the temperature range of processing is 550K to 700K for obtaining high ductility in the product. On the basis of microstructure and the ductility of the product, the temperature-strain rate regimes of damage due to cavity formation at particles and wedge cracking have been isolated for this alloy. The tensile fracture features recorded on the product specimens are in conformity with the above damage mechanisms. A high temperature treatment above $\approx$600K followed by fairly fast cooling gives solid solution strengthening in the alloy at room temperature. (8 refs.)

109409 Plastic flow phenomenology of 304 L stainless steel. S.L.Semiatin, J.H.Holbrook.

Metall. Trans. A (USA), vol.14A, no.8, p.1681-95 (Aug. 1983).

The isothermal plastic flow behaviour of annealed 304 L austenitic stainless steel in uniaxial compression and torsional modes of deformation has been established over a wide range of temperatures and strain rates. In uniaxial compression, it was found that high rates of strain hardening, which persist to large strains (≥ 0.7) at cold-working temperatures, are found only at small values of strain (≤ 0.2) at hot-working temperatures because of the influence of dynamic softening processes. The effect of deformation heating on flow behaviour, which occurs primarily at high strain rates, was most significant at cold-working temperatures. Deformation heating was observed to result in flow stress maxima and flow softening. A method of estimating high-strain rate, isothermal-flow curves in such instances was derived. Shear stress-shear strain curves derived from torsion tests exhibited dependences on temperature and strain rate similar to those observed in compression data. (35 refs.)

109410 Mechanical properties of large sections of low-carbon steel microalloyed with vanadium, cerium, and niobium. M.Ya.Belkin, V.P.Krivosheev, V.M.Belkin, V.T.Alekseenko, L.L.Litvinenko (Novo-Kramatorsk Machine Construction Factory, Kramatorsk Industrial Inst., USSR).

Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.756-9 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.7-10 (Nov. 1982).

Results are given from studies of the mechanical properties in various zones of large forgings of low-carbon steel from an ingot weighing 68 tons. It was found that microadditions of niobium, vanadium, and cerium improve the combination of mechanical properties—the ultimate tensile strength and particularly the proof stress increase substantially and the ductility also increases. Microadditions have an especially favorable effect on the proof stress and fracture toughness of the steel; these properties are quite uniform through the section. It should also be noted that the anisotropy of the properties is lower for the steel with microadditions, and the evenness of the properties through the section is much higher than for the steel without additions. (6 refs.)

109411 Effect of chromium content and heat treatment on creep of chromium bronze. D.K.Figurovskii, A.K.Nikolaev, V.M.Rozenberg (State Sci.-Res. & Design Inst. of Alloys & Treatment of Nonferrous Metals, USSR).

Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.828-31 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.61-3 (Nov. 1982).

Investigates the effect of heat treatment (which determines the stability of the structure) on the creep resistance of bronze containing 0.51 and 0.83% Cr (by weight). The bronze was water quenched from 980-1000°C and aged at 500 and 600° for 1 h. The structural changes were investigated using the Tesla BS-513 electron microscope. Creep tests were made in the range of 300-600°C under constant load on samples with a reduced section 100 mm long and 8 mm in diameter. The temperature was maintained within limits of ±1.5°. At testing temperatures below 0.5 T_m the structure of the alloy affected the creep resistance in the same way as during tensile strength tests. The more dispersed (but less stable) structure ensured higher strength and a lower steady creep rate. At temperatures above 0.5 T_m the less dispersed (but more stable) structure of the bronze was responsible for the lower creep rate. (8 refs.)

109412 Theoretical and experimental study of the plastic deformation of aluminium single crystals. II: Partially imposed plane compression. A.Skalli, J.H.Driver (Dept. Materiaux et Ingenierie, Ecole des Mines de Saint-Etienne, Saint Etienne, France), M.Wintenberger.

Mem. & Etud. Sci. Rev. Metall. (France), vol.80, no.6, p.293-302 (June 1983). In French.

For pt.I see ibid., vol.80, p.241, (1983). The method of Renouard and Wintenberger (1980) is applied to the case of large amplitude deformation in plane compression of FCC crystals under mixed conditions. The state of stress of slip amplitudes, crystal rotations and non-imposed deformations are calculated. (12 refs.)

109413 A structural study of the tensile drawing behavior of poly(ethylene terephthalate). S.R.Padibjo, I.M.Ward (Dept. of Phys., Univ. of Leeds, Leeds, England).

Polymer (GB), vol.24, no.9, p.1103-12 (Sept. 1983).

A study of single stage and two-stage drawing of poly(ethylene terephthalate) has been undertaken. Measurements of the modulus of the drawn films were combined with a range of structural measurements, including refractive index, X-ray diffraction and infrared spectroscopy. The development of molecular orientation during drawing is discussed in terms of the deformation of a molecular network, and reasons for the differences between single stage and two-stage drawing are proposed. The relationships between different measures of molecular orientation are considered with the aim of obtaining an understanding of the factors which influence the modulus values. It appears that the modulus relates primarily to the molecular chains which are in the extended trans conformation, irrespective of crystallinity. (15 refs.)

109414 Static and dynamic deformation mechanisms of a high-density polyethylene having row-nucleated crystalline texture of *a*-axis orientation as observed by orientation distribution function of crystallites. K.Shiro, K.Fujita, S.Suehiro, H.Kawai (Dept. of Polymer Chem., Kyoto Univ., Kyoto, Japan).

Polymer (GB), vol.24, no.9, p.1113-27 (Sept. 1983).

The rheo-optical properties of a high-density polyethylene having a row-nucleated crystalline texture of *a*-axis orientation were investigated in the machine direction (MD) and transverse direction (TD) of fabricating the specimen. The tensile complex dynamic compliance function J^* displays two dispersions designated as the α_1 and α_2 mechanical retardation processes with activation energies of about 21 and 35 kcal mol^{-1}, respectively, for both MD and TD specimens, and the complex dynamic stress-optical coefficient function M^* exhibits a single discrete dispersion designated as the α optical retardation process with an activation energy of about 24 kcal mol^{-1} for both specimens over the same frequency and temperature ranges as those covered for the dynamic mechanical measurements. The real and imaginary components of M^* converge from positive values to almost zero at the highest frequencies and lowest temperatures covered for both specimens, with the exception of the real component of the MD specimen which converges to a small but definitely negative value. The analysis of this anomalous behaviour of the MD specimen in terms of the optical retardation time spectrum has ascribed the negative convergence to a negative form birefringence that arises from a dynamic lamellar splaying or bending process responding in phase with the dynamic bulk stress. The dynamic X-ray diffraction studies have revealed the α optical dispersion and possibly the α mechanical dispersion to be mostly attributed to the crystal orientation dispersions involving intralamellar shearing processes, i.e. detwisting and tilting processes of the lamellar segments for the MD and TD specimens, respectively. (34 refs.)

109415 Influence of current-pulse duration on the rate of creep of zinc crystals. O.A.Troitskiy, V.I.Stashenko, V.I.Spitsyn.
Russ. Metall. (GB), no.1, p.141-4 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.164-8 (1982).
The creep of zinc crystals at the non-steady stage of 78K under the effect of current obeys the logarithmic law. The effect of pulsed currents is equivalent to applying additional effective stresses to the crystals. The deformation due to the current pulses of 110 to 240 μs durations (with $I_m=250$ A/mm^2 and $F=100$ Hz) increases; this effect is absent for pulses shorter than 100 μs. (7 refs.)

109416 Dependence of the long-term ductility of a Cr-MoV steel on changes in the structure. L.D.Mischenko, S.S.D'yachenko, V.P.Tarabanova.
Russ. Metall. (GB), no.1, p.172-5 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.202-5 (1982).
Under the long-term effect of temperature and stresses, two main processes causing structural changes take place in the structure of the steel: carbide coalescence and recrystallisation. The dependence of long-term ductility on the time factor for the heats of all the structural groups is governed by a common law. The δ-τ curves have a minimum. The time at which the curves passes through the minimum and the level of δ depends on the type and stability of structure formed in the steel. (3 refs.)

109417 Diagrams of structural states and maps of aluminium alloy structures. Yu.M.Vaynblat.
Russ. Metall. (GB), no.2, p.73-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.82-9 (1982).
It is shown that earlier proposed diagrams of structural states for a steady state stage of hot deformation of aluminium alloys form a basis for the control of the structure of semis; the diagrams are suppplemented with quantitative data on the structure and the deforming stress. The diagrams constructed in coordinates 'temperature of deformation—velocity of deformation' can serve as maps of mechanisms of deformation, the characteristic ranges of which are separated by lines of various values of the Zener-Holomon parameter. Division of diagrams into types, depending on the nature of the alloy, is proposed. Some examples of typical diagrams of structural states are given. (19 refs.)

109418 Estimation of the yield point of textured polycrystals (with computer calculation of the yield point of titanium). N.D.Reymer, R.A.Adamesku, P.V.Gel'd.
Russ. Metall. (GB), no.2, p.121-7 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.134-40 (1982).
A method has been devised for calculating the yield point of polycrystalline materials with arbitrary atomic structure and crystallographic texture. The results show the model of microplastic deformation and the method of calculating the yield point to be valid for materials with a hexagonal close-packed lattice. The type of crystallographic texture and its scatter in these materials make a decisive contribution to the yield point. In calculating $\sigma_{0.2}$ it is important to incorporate the second stage of microplastic deformation, since in this case there are a considerable number of grains that are plastically deformed. (12 refs.)

109419 Structure and properties of deformed alloys of the tungsten corner of the W-Mo-Re-Hf-C system. E.M.Savitskiy, K.B.Povarova, Yu.O.Tolstobrov, P.V.Makarov, E.K.Zavarzina, L.S.Kosachev, S.S.Semiletov, V.A.Balashov.
Russ. Metall. (GB), no.2, p.198-204 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.217-23 (1982).
Establishes the basic relationships of structure formation and the changes in mechanical properties during deformation of vacuum-melted low-alloy tungsten-base alloys in the W-Mo-Re-Hf-C system in which solid solution alloying (with molybdenum and rhenium) was employed and dispersion-hardened carbides of hafnium and tungsten were introduced. The introduction of up to 0.2 at.% Hf and up to 0.15 at.% C into tungsten-base solid solutions permits the formation of a dislocation structure during deformation, which is stabilised by the dispersed HfC particles, and the mechanical properties are improved. During hot and, in particular, during warm deformation a fibrous structure forms which gradually lowers the temperature of the ductile-brittle transition, and on reaching an overall reduction above 95% (for roads and wires of diameter below 3 mm) almost all the alloys were ductile at room temperature. (8 refs.)

109420 An investigation of the properties of internally oxidised Cu-Al-Ti-Hf alloys. V.L.Solopov, E.P.Daneliya, G.V.Daneliya, O.P.Lebasova.
Russ. Metall. (GB), no.3, p.98-103 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.3, p.114-20 (1982).
Internally oxidised Cu-Al-Ti-Hf alloys have higher strength properties with an insignificant increase in the specific electrical resistance compared with internally oxidised Cu-Al alloys known in the literature (1978). The best combination of the physico-mechanical properties is attained at small contents of titanium (0.01-0.05%) and hafnium (0.01-0.1%). (5 refs.)

109421 Effect of composition and structure on the hot ductility of CrMn corrosion-resisting steels. Ya.E.Gol'dshteyn, O.A.Bannykh, V.G.Mizin, A.E.Shelest, N.S.Khismatullina.
Russ. Metall. (GB), no.3, p.107-11 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.3, p.123-9 (1982).
The dependence of the hot ductility of the steel based on CrMnN austenite on its composition and phase transformations taking place during hot working has been examined. If the chromium content is higher than 16% and the manganese content exceeds 20%, the hot ductility of the steel greatly decreases. The reduction in the hot ductility of this steel is determined not as much by the amount of the alpha phase in the structure of worked metal as by the stability of the alpha phase and its susceptibility to breakdown with the precipitation of the sigma phase. The special features of failure of the sigma phase with the formation of colonies of microcracks which act as a basis for the subsequent development of macrodefects has been examined. The effect of nitrogen on the structure and properties of the steel is ambiguous. (5 refs.)

109422 Mechanism of hardening of high-molybdenum content maraging steel. Yu.E.Busalov, I.M.Kop'yev, H.Paul.
Russ. Metall. (GB), no.3, p.116-19 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.3, p.134-9 (1982).
Investigations were conducted into the dependence of the mechanical properties of the N9K20M14 maraging steel on the conditions of heat treatment after the preliminary working of wires with high reductions (96-99%). The optimum ageing temperature (approx. 500°C) at an ageing time of 2 h was determined. The mechanical properties of this steel after high-temperature, high-speed ageing (800°C, 0.75-1.5 s) have been examined, and show that the high-temperature ageing conditions result in a sharp rise in ductility (to 4%) compared with the low-temperature ageing conditions (δ=0.5-1%), and the high tensile strength is retained (410-420 kgf/mm^2). (4 refs.)

109423 Deformation-mechanism maps for silicon carbide. P.M.Sargent, M.F.Ashby (Engng. Dept., Cambridge Univ., Cambridge, England).
Scr. Metall. (USA), vol.17, no.7, p.951-7 (July 1983).
The maps summarise available data on the hardness, compressive strength and creep strength of hot pressed silicon carbide. (35 refs.)

109424 Orientation dependence of creep behavior of single crystal γ' (Ni_3Al). D.M.Shah (Materials Engng. & Res. Lab., Pratt & Whitney Aircraft Group, Middletown, CT, USA).
Scr. Metall. (USA), vol.17, no.8, p.997-1002 (Aug. 1983).
It is shown that qualitatively the creep anisotropy of single phase γ' is similar to nickel-base superalloys and can be quantitatively normalized in terms of a linear superposition of shear strains on either octahedral or cube or both slip systems. (25 refs.)

109425 Scalar and vector properties of anisotropic materials in a complex stressed state. II. Plastic deformations of anisotropic materials under simple loading. B.I.Koval'chuk, V.V.Kosarchuk, A.A.Lededev (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.8, p.1129-38 (Aug. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.8, p.114-21 (Aug. 1982).
For pt.I see ibid., vol.14, no.3, p.25 (1982). Examines small plastic deformations of anisotropic materials under a simple loading. Aluminum alloys D16T, Amg6, and AMtsS—were selected as test materials for the investigations. The tests were conducted at normal temperatures by loading thin-wall tubular specimens with an axial force and internal pressure with the realization of radial paths in real-stress space. It is demonstrated that the alloys under investigation are transversally isotropic with a plane of isotropy perpendicular to the Z axis of the specimen. The difference of the yield points in tension and compression for alloys D16T and AMg6 does not exceed 7%. For alloy AMtsS, the yield point in compression is lower than that in tension by 12%. (20 refs.)

109426 Effect of stacking-fault energy on the parameters of high-temperature creep of nickel-cobalt alloys. L.M.Nerodenko, E.V.Dabizha (E.O. Paton Inst. of Electric Welding, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.10, p.1331-7 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.40-6 (Oct. 1982). [received: Sept. 1983]
The authors investigated, with regard to the structural model, the effect of stacking faults on dislocation parameters which determine creep resistance in the steady-state stage. These parameters include the size of subgrains L, the spacing of steps on screw dislocations *l*, the microscopic elasticity limit, the mobile dislocation density, and the dislocation rate inside the subgrains and during crossing of the subgrain boundary. Two alloys of the nickel-cobalt system (Ni-25% Co and Ni-65% Co) were investigated. The analysis showed that the dependence of parameter n as a coefficient of retardation of mobile dislocation by the subboundaries on the size of the SFE is determined, apparently, by a change in the character of the subgrain boundaries caused by variation of the SFE in Ni-Co alloys. (39 refs.)

109427 Influence of pulsed current peak on the creep rate of zinc crystals. V.I.Stashenko, O.A.Troitskii (Phys. Chem. Inst., Acad. of Sci., Moscow, USSR).
Strength Mater. (USA), vol.14, no.10, p.1337-41 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.46-9 (Oct. 1982). [received: Sept. 1983]
An investigation was made of the creep of zinc crystals in the nonsteady stage at 78K under the action of pulsed currents of different peaks. The thermal portion of the current action was isolated. It was established that the creep of crystals in the mechanism of the electron-plastic effect is described by a logarithmic relationship as in normal deformation. The effective stresses caused by the drifting electrons entrapping the dislocations were determined. They were equal to $(1.7\text{-}7)\times10^4$ Pa with different values of L_m. The strain hardening exponents of crystals deformed with and without a current were also determined. (6 refs.)

109428 Rules of the plastic behavior of metal in deformation. V.S.Biront (M.I. Kalinin Krasnoyarsk Inst. for Nonferrous Metals, USSR).
Strength Mater. (USA), vol.14, no.10, p.1341-4 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.49-53 (Oct. 1982). [received: Sept. 1983]
An approach is proposed for determining the quantitative characteristics of the limiting condition of a material being deformed under the action of external static stresses and additional actions (temperature, additional loads by alternating sign stresses, ultrasonic action, etc.) which makes it possible to more reliably solve problems of crack formation and propagation in a metal being deformed in failure. With use of the relationship established it is possible to calculate the stresses and strains occurring in machine parts under complex stressed conditions during service. (2 refs.)

109429 Study of the behavior of closed steel spherical shells with single-stage internal explosive loading. V.I.Tsypkin, A.M.Cheverikin, A.G.Ivanov, S.A.Novikov, V.N.Mineev, A.T.Shitov.
Strength Mater. (USA), vol.14, no.10, p.1353-9 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.59-64 (Oct. 1982). [received: Sept. 1983]
Results are given of numerical and experimental studies devoted to revealing regularities in the behavior of different thickness spherical shells in the plastic deformation range up to failure with single-stage internal explosive loading. The deformation state was considered for closed spherical shells of mass M with outer radius R_0 and wall thickness δ_0 filled with air under normal conditions, and with an internal explosion of a change of explosive (VV). Shells were made of steel 35 and annealed to remove residual stresses in the welded joint zone. Mechanical properties of the shell material were monitored by testing control specimens. Tests were carried out on shells with a uniform internal radius $R_i=153$ mm and different wall thickness, and also geometrically similar shells reduced in size by a factor of four. (12 refs.)

109430 Certain features of the change in physicomechanical properties of type SSTF material in aging under humid subtropical conditions. E.A.Eskin, K.I.Kolesnik, A.S.Petrov, O.V.Startsev, V.P.Meletov (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.10, p.1392-7 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.91-6 (Oct. 1982). [received: Sept. 1983]
An investigation was made of the stability of the properties of type SSTF material, which is based on three-dimensional glass skeletons and phenol-formaldehyde binder, during a two-year hold under humid subtropical conditions, with a relative humidity of 70-98% and an average monthly temperature of the hottest month of more than 22°C. The storage conditions and exposure time had a significant influence on the surface layer condition and change in physicomechanical characteristics of SSTF material. During a two-year exposure there was a reduction in the strength and modulus of elasticity in bending, averaging 15-25%. There was a more significant (by 30-45%) decrease in compressive strength in the direction parallel to the layers. The primary reduction in the strength and modulus of elasticity both in bending and in compression occurred in the first 5 to 8 months of exposure. During aging there was an increase in porosity and a change in the value of the relative temperature deformation, which is an indication of occurrence of the physicochemical processes leading to the reduction in the mechanical properties of the material. (7 refs.)

109431 Influence of creep on the precipitate structure under conditions of long-term creep—investigation of a Fe-Cu model alloy. O.Schulze, G.Sauthoff (Max-Planck-Inst. fur Eisenforschung GmbH, Dusseldorf, Germany).
Z. Metallkd. (Germany), vol.74, no.8, p.504-12 (Aug. 1983). In German.
The precipitation behaviour of a Fe-Cu model alloy (1.8 mass%Cu) with and without concurrent creep deformation was studied at 550°C and 650°C. The strain rates were in the range of order of $10^{-8}\ s^{-1}$. In this case the deformation results from the climb of a practically constant number of dislocations. The experiments covered the ageing stages of the precipitate during which the transition from (partially) coherent and practically spherical particles to incoherent rod-like ones occurred. An influence of the concurrent creep on the ageing behaviour of the precipitate by accelerating the coherency decrease could not be found. The conclusions are valid for the behaviour of corresponding special carbides in creep-resistant steels. (26 refs.)

109432 Strain distribution and load transfer characteristics of a Cu-9.6 wt.% Al dual-phase structure. A.H.Yegneswaran, K.Tangri (Metall. Sci. Labs., Univ. of Manitoba, Winnipeg, Manitoba, Canada).
Z. Metallkd. (Germany), vol.74, no.8, p.521-4 (Aug. 1983).
The behaviour of the constituents of the dual-phase Cu-9.6 wt.% Al alloy during deformation was studied by both qualitative and quantitative metallographic analysis. The strain in the martensite was calculated and it was found that martensite strain increases with composite strain approaching the isostrain condition only near the fracture of the specimen. The estimated load transfer between the α matrix and β' grains at different strain levels clearly shows that the deformation of martensite in the dual phase alloy starts at a specimen strain of approximately 15%. (20 refs.)

109433 Superplasticity of high carbon steels. R.Nowosielski, L.Cieslak (Inst. fur Metallkunde und Schweisstech., Tech. Univ., Gliwice, Poland).
Z. Metallkd. (Germany), vol.74, no.8, p.549-56 (Aug. 1983). In German.
The investigation of superplastic phenomenon in carbon steels containing 0.8, 1.3 and 1.6%C, with different initial structures have been performed. Relations of flow stress, strain-rate sensitivity and elongation to strain rate were determinated. Values of the threshold stresses and the activation energy of superplastic deformation were measured too. The experimental results for α-Fe were compared with computed data according to the Ashby-Verrall model. (26 refs.)

109434 Drawability of sheet material. C.Marique, R.D'Haeyer, J.Gouzou, J.Mignon, A.Bragard.
Report EUR 6653 EN, Comm. European Communities, Luxembourg (1983), 51 pp. Contract 7210.KC/204.
This research has been devoted principally to the development and to the practical use of a mathematical model which allows one to predict the local strains and the proneness to wrinkling in deep drawing of cylindrical and conical parts, made from cold rolled sheets. The characterisation of the steels and the determination of the basic equations needed for the model's use are assessed by a study of the strain-hardening laws. A mathematical simulation on the onset of the necking phenomenon and its development is made. It is possible to predict the 'stress-strain' curve as delivered by a tensile test in plane strain. Practical uses of the model are presented: comparison between calculated and measured local strains values, drawing loads prediction, assessment of the influence of different parameters: lubrication, tooling geometry etc. (5 refs.)

109435 **Fracture of phosphate-bonded high-alumina refractories.** F.J.Gonzalez (Pennsylvania State Univ., University Park, PA, USA), J.W.Halloran.
Am. Ceram. Soc. Bull. (USA), vol.62, no.7, p.798-803 (July 1983).
Phase development and mechanical properties were studied in model refractories consisting of tabular alumina aggregate bonded by phosphoric acid and one of several calcined aluminas. Elastic modulus, flexural strength, work-of-fracture and fracture toughness were determined from room temperature to 1200°C. The least reactive alumina showed the best properties. All properties displayed a maximum at 800°C. This behavior is consistent with the presence of a glassy bonding phase. (6 refs.)

109436 **Development of Ti-6A1-4V gas bottle for satellite applications.** V.Ramachandra, G.Thomas, M.J.Nair, B.K.Sarkar (Metall. & Ceramics Div., Vikram Sarabhai Space Centre, Trivandrum, India).
Trans. Indian Inst. Met., vol.35, no.2, p.127-36 (April 1982). [received: Aug. 1983]
Ti-alloys, because of their high specific strength and passivity to liquid propellants, are of great interest to space technologists. Utilisation of Ti-6 Al-4 V (24×10^5 cm specific strength) for gas bottle application in satellites has therefore been extensive. Such gas bottles are presently imported and a programme was therefore undertaken at the Vikram Sarabhai Space Centre to develop this alloy gas bottle indigenously. The authors describe the successful fabrication of the alloy into gas bottles capable of withstanding burst pressures of the order of 1000 kg/cm^2. The testing of the gas bottles for the designed burst pressure and the results obtained are highlighted. (10 refs.)

109437 **Electron microfractography of fatigue fracture in aluminium alloys.** C.S.Harendranath, A.K.Mallik (Indian Inst. of Technol., Bombay, India).
Trans. Indian Inst. Met., vol.35, no.5, p.415-20 (Oct. 1982). [received: Aug. 1983]
The low cycle fatigue crack propagation stage of two aluminium-zinc-magnesium alloys subjected to various heat treatment cycles has been investigated, using electron microfractography. In particular, the nature and morphology of fatigue striations as related to heat treatment and properties are discussed. The striation morphology was found to be influenced by heat treatment. While the single aged and double aged alloys showed only regular, well defined ductile striations, thermomechanically treated alloys exhibited a transition in striation morphology from near ductile to brittle like ones. The thermomechanically treated alloys were also found to possess significantly higher low cycle fatigue lives as compared to the single and double aged alloys. (8 refs.)

109438 **Regularities of cyclic crack resistance under effect of contact stresses.** O.M.Romaniv, A.V.Dobrik, V.N.Siminkovich.
Dopov. Akad. Nauk UkRSR. Ser. A (USSR), no.8, p.35-8 (1983). In Ukrainian.
The contact stress effect on fatigue crack propagation in structural roll steel is estimated on the basis of a new experimental procedure. Contact compressing stresses are shown to cause a significant reduction of the crack growth kinetics in the field of pulsating tensile stresses as well as a considerable increase (two-fold) of threshold stress intensity factors ΔK_{th}. The contact stress influence intensity is a function of contact loading, the propagating crack length and roll steel strength. (5 refs.)

109439 **Correlations among growth law of small cracks, low cycle fatigue law and applicability of Miner's rule.** Y.Murakami (Dept. of Mech. & Strength of Solids, Kyushu Univ., Fukuoka, Japan), S.Harada, T.Endo, H.Tani-Ishi, Y.Fukushima.
Eng. Fract. Mech. (GB), vol.18, no.5, p.909-24 (1983).
The initiation and propagation process of a small crack in low-cycle fatigue of a medium carbon steel is observed in detail by the plastic replica method. It is found that the Manson-Coffin relation is virtually the same as the crack growth law of a small crack; more than 90% (almost 100%) of the fatigue life of plain specimens is occupied by the crack propagation process. From this viewpoint, the ambiguity in the definition of the initiation of 'an engineering-size crack' can be removed. The effects of prior fatigue history on the growth rate of a small crack are investigated systematically using special specimens containing an artificial small hole with diameters of 40, 100 and 200 μm. Prior fatigue history which may be accumulated at the region where a crack will later propagate hardly influences the crack growth rate, i.e. prior fatigue history itself should not be regarded as fatigue damage. This is an essential condition for Miner's rule to apply. (31 refs.)

109440 **Model of fatigue crack propagation by damage accumulation at the crack tip.** G.Chalant, L.Remy (Centre des Materiaux, Ecole des Mines de Paris, ERA CNRS, Evry, France).
Eng. Fract. Mech. (GB), vol.18, no.5, p.939-52 (1983).
Modelling fatigue crack propagation by damage accumulation at the crack tip originally proposed by McClintock (1963) is reworked out using metallurgical considerations. On a physical basis it is shown that the validity of such models is actually confined to the low crack growth rate range corresponding to stage I growth such as along crystallographic planes. At higher crack growth rates there is a transition to plastic stretching mechanisms which could be described by crack opening displacement models. An evaluation of two models has been carried out on a ^{33}Co Ni alloy where extensive information was available: both are based on the strain singularity as computed by Tracey (1976) from a finite element analysis of plane strain small scale yielding and as adapted to cyclic loading under Rice's hypothesis (1967) and taking the grain as the critical element below which size continuum mechanics do no longer apply. It is pointed out that the use of this strain singularity which is not able to account to crack closure, renders models unable to predict experimental crack growth rates curves but only intrinsic curves relating the growth rate to the effective stress intensity amplitude as defined by Elber. (36 refs.)

109441 **Fatigue crack propagation in steels.** Xiulin Zheng (Dept. of Material Engng., North-Western Polytech. Univ., Xian, Shaanxi, China), M.A.Hirt.
Eng. Fract. Mech. (GB), vol.18, no.5, p.965-73 (1983).
From previous investigations of the mechanisms of both fracture and fatigue crack propagation, the static fracture model proposed by Lal and Weiss (1978) may be thought as reasonable for describing fatigue crack propagation in metals at both low and intermediate stress intensity factor ranges ΔK. Recent progress in fatigue crack propagation indicates that it is not only possible, but also necessary, to modify this static fracture model. Based on the modified static fracture model, the effective stress intensity factor range ΔK_{eff}, which is defined as the difference between ΔK and the fatigue crack propagation threshold value ΔK_{th}, is taken as the governing parameter for fatigue crack propagation. Utilising the estimates of the theoretical strengths of metals employed in industry, a new expression for fatigue crack propagation, which may be predicted from the tensile properties of the metals, has been derived. The correlation between the fatigue crack propagation rate and the tensile properties is thus revealed. The new expression fits the test results of fatigue crack propagation of steels below 10^{-3} mm/cycle and indicates well the effect of stress ratio on the fatigue crack propagation rate. (33 refs.)

109442 **Quasistatic thermal crack growth in unidirectionally fiber reinforced composite materials.** K.Herrmann (Inst. of Mech., Paderborn Univ., Paderborn, Germany), H.Braun.
Eng. Fract. Mech. (GB), vol.18, no.5, p.975-96 (1983).
Micromechanical investigations concerning the quasistatic thermal crack propagation in self-stressed unidirectionally reinforced composite structure with a low-fiber volume fraction have been performed. Thus, in order to gain certain microstructural informations about the thermal shock resistance of those reinforced composites different cracked unit cells of several two-phase composites as well as ensembles of such composite microcomponents are considered which are subjected to thermal loading. Therein the principal facets of composite material failure theories, emphasizing matrix cracking, fiber breaking and interfacial debonding, respectively, have been studied. The resulting mixed boundary-value problems of the stationary plane thermoelasticity are solved numerically by using standard finite element programs. Further, the influences of the fiber diameters, different shapes of the fiber-matrix interfaces as well as of the external boundaries of the microcomponents on the crack opening displacement $u_y{}^c$ and the opening mode stress intensity factor K_I, respectively, have been investigated. Numerical results are given for an Al_2O_3 matrix/molybdenum fiber composite by consideration of different crack configurations. (34 refs.)

109443 **An engineering interpretation of pop-in arrest and tearing arrest in terms of static crack arrest, K_{Ia}.** F.J.Witt (Nuclear Energy Systems, Westinghouse Electric Corp., Pittsburg, PA, USA).
Eng. Fract. Mech. (GB), vol.18, no.5, p.997-1010 (1983).
When fracture toughness specimens are rested under displacement controlled conditions, they are often observed to exhibit unstable cleavage fracture followed by arrest of the cleavage mode wherein a significant load remains on the specimen (pop-in arrest). This behaviour carries over into the ductile tearing regime wherein tearing may occur rapidly identified by load reduction and then proceeds at a discernible less rate (tearing arrest). Both these behaviours represent an initiation condition followed by an arrest condition. It is demonstrated that from either of the arrest conditions an arrest value may be determined which, for available experimental data, is shown to be an engineering estimate for the static crack arrest toughness K_{Ia}. A general lower bound property for the arrest value is postulated based on reference information. A data analysis procedure is outlined and K_{Ic} and K_{Ia} estimate from sixty-eight 1/2, 1 and 2 in. thick compact specimens from two steels (A 533 Grade C Class 1 and AISI 1018) tested between −40° F and 200° F are summarized. The crack arrest estimates are seen to compare favorably with K_{Ia} results obtained by other investigators using 2 in. thick specimens. Also it is demonstrated that when failure is by fully ductile tearing, the crack arrest toughness is at least equal to the estimate for K_{Ic} for the specimen. (15 refs.)

109444 **Fracture mechanics approach to fatigue crack initiation from deep notches.** K.Tanaka (Dept. of Mech. Engng. & Mech., Lehigh Univ., Bethlehem, PA, USA), Y.Nakai, R.Kawashima.
Eng. Fract. Mech. (GB), vol.18, no.5, p.1011-23 (1983).
Fracture mechanics approach is applied to fatigue crack initiation at the tips of deep, blunt notches including those with very small notch-tip radius. The theoretical relations between the stress intensity range ΔK_ρ and the notch-tip radius ρ for a fixed life for crack initiation were derived based on the models of dislocation-dipole accumulation and blocked slip-band. Those are approximated by a simpler equation: $\Delta K_\rho/\Delta K_0=(1+\rho/\rho_0)^{1/2}$ where ΔK_0 and ρ_0 are material constants which are related to the fatigue strength of smooth specimens of $\Delta\sigma_0$ as $\Delta\sigma_0=2\Delta K_0/(\pi\rho_0)^{1/2}$. The results of experiments done with bluntly notched compact tension specimens of a structural low-carbon steel agree with the above relation between $\Delta K_\rho/\Delta K_0$ and ρ/ρ_0. The method to predict ΔK_0, ρ_0 and $\Delta\sigma_0$ from the fatigue data of cracked and smooth specimens is proposed. (32 refs.)

109445 **Crack opening areas in pressure vessels and pipes.** C.Wuthrich (Brown Boveri Res. Center, Baden, Switzerland).
Eng. Fract. Mech. (GB), vol.18, no.5, p.1049-57 (1983).
Summarizes different methods for the calculation of crack opening areas in pressure vessels and pipes. In the case of constant membrane stresses the

crack opening area is related to the stress intensity factor. This concept is applied to axial and circumferential cracks in pipes and to meridional cracks in spherical pressure vessels. Plasticity effects are taken into account in the framework of Dugdale's model. Lower and upper bound values for the leak areas are discussed and related to the problems of leak detection and jet forces acting on leaking pipes. (8 refs.)

109446 Determination of the ideal strength of metal microcrystals. I.M.Mikhailovskii, P.Ya.Poltinin, L.I.Fedorova.
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.186-91 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
An investigation was made of the strength characteristics of microcrystals of submicron transverse size of some metals with the BCC and FCC lattices. This was done for thin foils of copper, nickel, molybdenum, and chromium and for thin filaments of iridium and tantalum. The study was carried out by loading with ponderomotive forces created by an electric field. In contrast to metal whiskers, the investigated microcrystals showed no scale dependence of the strength or of the variance of the strength. An analysis of the theoretical and experimental data led to the conclusion that ideal crystals with the FCC lattice fractured as a result of homogeneous shear along close-packed planes under the action of stresses in the range (0.026-0.041)G, where G is the shear modulus. In the case of the BCC crystals a lattice instability was the likely fracture mechanism. (21 refs.) *A.T.*

109447 Relationship between the parameters of pit fracture and the characteristics of the structure of heat-improved steel. V.M.Goritskii, I.A.Guseva (Central Sci.-Res. Design Inst. for Building Metal Constructions, Moscow, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.192-4 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
An investigation was made of the influence of the compositon of 10KhSND laboratory steel and of 10KhN1M industrial steel in the thermally improved state (quenching from 920°C in water, annealing at 680°C for 1.5 h. cooling in air) and after ageing at 400 and 450°C on the microstructure of pit fracture surfaces. An electron-microscopic study of foils and carbon replicas revealed a linear relationship between the size of carbide particles, size of micropores, and size of fracture pits. (3 refs.) *A.T.*

109448 The effect of water vapor on fatigue crack tip mechanics in 7075-T651 aluminum alloy. D.L.Davidson, J.Lankford (Dept. of Materials Sci., Southwest Res. Inst., San Antonio, TX, USA).
Fatigue Eng. Mater. & Struct. (GB), vol.6, no.3, p.241-56 (1983).
Strains very near a growing fatigue crack have been computed from measured material displacements, both for a very dry environment and for humid air. Significant differences in crack tip strains and crack tip opening displacements occur in these environments, with crack tip deformation in water vapor evidencing less plasticity than the dry environment. These quantitative results are incorporated into a previously developed mathematical model which is based, in part, on dynamic observations of intermittent crack growth. Fractography is shown to support the concepts of intermittent crack advance and decreased crack tip plasticity due to environmental water vapor. (19 refs.)

109449 On the transition from near-threshold to intermediate growth rates in fatigue. M.R.James, W.L.Morris, A.K.Zurek (Rockwell Internat. Sci. Center, Thousand Oaks, CA, USA).
Fatigue Eng. Mater. & Struct. (GB), vol.6, no.3, p.293-305 (1983).
Evidence is presented that the cyclic stress intensity threshold for fatigue crack growth in Al 2219-T851 is associated with a critical maximum value of stress intensity, K_c. This relationship is discovered by measuring the local value of stress intensity at the crack tip which is less than the applied stress intensity because of fatigue induced compressive residual stresses in the plastic zone. Crack growth rates and values of the crack tip residual stress are measured as functions of load ratio. For local stress intensities greater than K_c, the growth rate follows a power-law relationship, increasing monotonically with ΔK. For local stress intensities below K_c, growth rates are also sensitive to the cyclic stress range, $\Delta\sigma$. If the stress range is small, a threshold to growth, typical of long cracks, is seen. When the cracks are short and $\Delta\sigma$ exceeds a critical value, growth rates are a complex function of both $\Delta\sigma$ and ΔK. This behavior is attributed to the effect of $\Delta\sigma$ on the propagation of the crack front past obstacles such as grain boundaries. (40 refs.)

109450 Fracture of metastable tetragonal zirconia crystals. D.Michel, L.Mazerolles, M.Perez y Jorba (Lab. de Chimie Appliquee de l'Etat Solide, Vitry sur Seine, France).
J. Mater. Sci. (GB), vol.18, no.9, p.2618-28 (Sept. 1983).
Crystals of single-phased metastable tetragonal zirconia (MTZ) were prepared from skull-melting at the composition ZrO_2-3 mol.% M_2O_3 (M=Y, Yb or Gd). The fracture of the tetragonal crystals occurred differently than for the cubic stabilized zirconia ones. The toughness was much higher for the tetragonal specimens and the cleavage planes were not the same as for the fluorite crystals. The results were interpreted by considering the domain microstructure induced by the cubic→tetragonal phase transformation undergone by the crystals. (63 refs.)

109451 The influence of mean stress on fatigue crack propagation in dual phase low carbon steel. T.Ishihara (Ishikawajima-Harima Heavy Industries Co. Ltd., Aero-engine & Space Operations, Tokyo, Japan).
J. Mater. Sci. (GB), vol.18, no.9, p.2629-38 (Sept. 1983).
In a low carbon steel, containing martensite encapsulated islands of ferrite, second-stage fatigue crack growth rate is not influenced by the mean stress. However, in steel with ferrite encapsulated islands of martensite, crack growth rate is influenced by each mean stress because its microfracture mode changes from slipping to static. An acceleration of crack growth is mainly influenced by the number of continuous cleavage facets in each matrix. (9 refs.)

109452 Kinetics of shear-activated indentation crack initiation in soda-lime glass. B.R.Lawn, T.P.Dabbs, C.J.Fairbanks (Center for Materials Sci., NBS, Washington, DC, USA).
J. Mater. Sci. (GB), vol.18, no.9, p.2785-97 (Sept. 1983).
The initiation of radial cracks in Vickers indentation of soda-lime glass is found to be strongly rate dependent. For long contact durations the radial cracks pop in during the indentation event, at a reproducible stage of the unloading half-cycle; for short contacts the pop-in occurs after the event, with considerable scatter in delay time. The phenomenon is interpreted in terms of an incubation time to develop a critical nucleus for the ensuing fracture. Increasing either the water content of the environment or the peak contact load diminishes the incubation time. Scanning electron microscopy of the indentation patterns indicates that the sources of the crack nuclei are constrained shear faults within the deformation zone. A qualitative model is developed in terms of a two-step process, precursor faulting followed by crack growth to pop-in instability. Moisture may influence both these steps, in the first by interfacial decohesion and in the second by slow crack growth. The implications of these results in connection with the basic mechanical properties of brittle solids, particularly strength, are considered. (37 refs.)

109453 Propagation of stress corrosion cracks in aligned glass fibre composite materials. J.N.Price, D.Hull (Dept. of Metall. & Materials Sci., Univ. of Liverpool, Liverpool, England).
J. Mater. Sci. (GB), vol.18, no.9, p.2798-810 (Sept. 1983).
A modified fracture toughness test has been used to measure the growth of cracks in unidirectional glass fibre/polyester resin composite materials in the presence of a dilute hydrochloric acid. Crack growth rates perpendicular to the fibre axis have been measured over a range of stress intensities. Scanning electron microscope studies of the fracture surfaces have shown that the micromechanisms of nucleation and propagation are dependent on stress intensity. The use of crack growth data to predict component lifetimes and the existence of inherent flaws in the material are discussed. (16 refs.)

109454 The effect of heat treatment on plane strain fracture of glassy polymers. M.Ishikawa, I.Narisawa (Dept. of Fiber & Polymer Engng., Yamagata Univ., Yonezawa, Japan).
J. Mater. Sci. (GB), vol.18, no.9, p.2826-34 (Sept. 1983).
The effect of annealing on the plane strain fracture of round-notched polycarbonate and poly(methyl methacrylate) bars has been investigated. Morphological observations of thin sections and fracture surfaces revealed that the fracture initiated from internal crazes which were nucleated at the tip of a local plastic zone. The critical hydrostatic stresses for internal craze nucleation were nearly constant regardless of annealing, while the shear yield stress increased with increasing annealing time. The reduction in toughness by annealing can be ascribed to the decrease of the maximum extent of the plastic zone which gives the critical hydrostatic stress for craze nucleation. (16 refs.)

109455 Slow crack growth behavior in transformation-toughened Al_2O_3-$ZrO_2(Y_2O_3)$ ceramics. P.F.Becher (Metals & Ceramics Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.485-8 (July 1983).
Significant increases in the critical fracture toughness (K_{IC}) over that of alumina are obtained by the stress-induced phase transformation in partially stabilized ZrO_2 particles which are dispersed in alumina. More importantly, improved slow crack growth resistance is observed in the alumina ceramics containing partially stabilized ZrO_2 particles when the stress-induced phase transformation occurs. Thus, increasing the contribution of the ZrO_2 phase transformation by tailoring the Y_2O_3 stabilizer content not only increases the critical fracture toughness (K_{IC}) but also the K_{Ia} to initiate slow crack growth. For example, crack velocities $(\nu)\geq 10^{-9}$ m/s are obtained only at $K_{Ia}\geq 5$ MPa.m$^{1/2}$ in transformation-toughened ($K_{IC}=8.5$ MPa.m$^{1/2}$) composites vs $K_{Ia}\geq 2.7$ MPa.m$^{1/2}$ for comparable velocities in composites where the transformation does not occur ($K_{IC}=4.5$ MPa.m$^{1/2}$). This behavior is a result of crack-tip shielding by the dissipation of strain energy in the transformation zone surrounding the crack. (16 refs.)

109456 Dynamic fatigue of a machinable glass-ceramic. K.K.Smyth, M.B.Magida (NASA-Goddard Space Flight Center, Greenbelt, MD, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.500-5 (July 1983).
To assess the stress-corrosion susceptibility of a machinable glass-ceramic, its dynamic fatigue behavior was investigated by measuring its strength as a function of stress rate. Fracture mechanics techniques were used to analyze the results for the purpose of making lifetime predictions for components of this material. This material was concluded to have only moderate resistance ($N=30$) to stress corrosion in ambient conditions. The effects of specimen size on strength were assessed for the material used in this study; it was concluded that the Weibull edge-flaw scaling law adequately describes the observed strength-size relation. (15 refs.)

109457 Relation between multiregion crack growth and dynamic fatigue of glass using indentation flaws. P.Chantikul (Dept. of Appl. Phys., School of Phys., Univ. of New South Wales, Kensington, NSW, Australia), B.R.Lawn, H.Richter, S.W.Freiman.
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.515-18 (July 1983).
The influence of transport-limited kinetic crack growth on the fatigue properties of soda-lime glass was examined. Dynamic fatigue data were taken on specimens with controlled indentation flaws and were compared with the predicted response from measured crack velocity characteristics. Heptane was used as the operational test environment because of its pronounced crack velocity plateau; control tests in water served to establish a baseline reference for comparing the results. Fractographic observations using a stress wave marker technique showed a complex growth history for flaws broken in heptane compared to that for flaws broken in water. The magnitude of the predicted region II influence is too small to be detected in the dynamic fatigue results, even allowing for the relatively high degree of data reproducibility. The implications of this conclusion for lifetime predictions are discussed. (21 refs.)

109458 Fracture mechanics for delamination problems in composite materials. S.S.Wang (Dept. of Theoretical & Appl. Mech., Univ. of Illinois, Urbana, IL, USA).
J. Compos. Mater. (USA), vol.17, no.3, p.210-23 (May 1983).
A fracture mechanics approach to the well-known delamination problem in composite materials is presented. Based on the theory of anisotropic laminate elasticity and interlaminar fracture mechanics concepts, the composite delamination problem is formulated and solved. The exact order of the delamination crack-tip stress singularity is determined. Asymptotic stress and displacement fields for an interlaminar crack are obtained. Fracture mechanics parameters such as mixed-mode stress intensity factors, K_I, K_{II}, K_{III}, and the energy release rate, G, for composite delamination problems are defined. To illustrate the fundamental nature of the delamination crack behavior, solutions for edge-delaminated graphite-epoxy composites under uniform axial extension are presented. Effects of fiber orientation, ply thickness, and delamination length on the interlaminar fracture are examined. (17 refs.)

109459 Fatigue crack propagation in random short-fiber SMC composite. S.S.Wang, E.S.-M.Chim, N.M.Zahlan (Dept. of Theoretical & Appl. Mech., Univ. of Illinois, Urbana, IL, USA).
J. Compos. Mater. (USA), vol.17, no.3, p.25-66 (May 1983).
An investigation of the kinetics of fatigue crack growth in a random short-fiber reinforced SMC composite is presented. Experiments were conducted on notched SMC-R50 composite specimens subjected to cyclic uniaxial tensile and mixed-mode fatigue loading. Fatigue crack propagation rates were studied in terms of fracture mechanics parameters. A power-law relationship between the crack growth rate and the cyclic stress intensity factor range was obtained for the SMC-R50 composite under various fatigue loading modes. The value of the exponent in the power-law equation was found to be much higher for the composite than values reported for metals and some structural polymers. A fractographic study of fatigue fracture surfaces was also conducted. Mechanisms of fatigue crack growth in the SMC-R50 composite were identified. A mechanical model is then proposed for further study of the mechanics of fatigue crack growth in random short-fiber SMC composites. (14 refs.)

109460 Energy absorption of composite materials. G.L.Farley (US Army Res. & Technol. Labs., AVRADCOM, Langley Res. Center, Hampton, VA, USA).
J. Compos. Mater. (USA), vol.17, no.3, p.267-79 (May 1983).
The energy absorption characteristics of selected composite material systems and compares the results with aluminum. Composite compression tube specimens were fabricated with both tape and woven fabric prepreg using graphite/epoxy (Gr/E), Kevlar epoxy (K/E) and glass/epoxy (Gl/E). Chamfering and notching one end of the composite tube specimen reduced the peak load at initial failure without altering the sustained crushing load, and prevented catastrophic failure. Static compression and vertical impact tests were performed on 128 tubes. The results varied significantly as a function of material type and ply orientation. In general, the Gr/E tubes absorbed more energy than the Gl/E or K/E tubes for the same ply orientation. The [0/±15] Gr/E tubes absorbed more energy than the aluminum tubes. Gr/E and Gl/E tubes failed in a brittle mode and had negligible post crushing integrity, whereas the K/E tubes failed in an accordian buckling mode similar to the aluminum tubes. (7 refs.)

109461 Effect of alloying elements on the hydrogen embrittlement of vanadium at moderate temperatures. S.Morozumi (Res. Inst. for Iron, Steel & Other Metals, Tohoku Univ., Sendai, Japan), K.Suzuki.
J. Jpn. Inst. Met. (Japan), vol.47, no.8, p.704-10 (Aug. 1983). In Japanese.
In order to investigate the effect of alloying elements on the hydrogen embrittlement of vanadium at moderate temperatures, the metal was alloyed up to about 20 atomic per cent with molybdenum as an endothermic occluder and with titanium as an exothermic occluder, respectively, and then the specimens were hydrogenated up to about 10 atomic per cent of hydrogen. The specimens were tensile tested in the temperature range from room temperature to 573K. Both of molybdenum and titanium increased the solubility limit of hydrogen in vanadium, which was measured by the internal friction method. The alloying elements deteriorated vanadium for hydrogen embrittlement, by increasing the strength and lowering the ductility. Therefore, the ductile-brittle transition temperature (DBTT) of hydrogenated alloys, which was determined as a temperature at which just half of the reduction in area of unhydrogenated specimen was obtained in the hydrogenated specimen, was located in the solid solution region as to hydrogen as well as alloying elements at moderate temperatures in phase diagrams. The brittle fracture mode was different between V-Mo and V-Ti alloys. (10 refs.)

109462 Reloading stress relaxation behavior and rupture for 19Cr-9Ni-1.4Mo-1.4W-Nb bolting steel. C.Tanaka, T.Ohba (Nat. Res. Inst. for Metals, Tokyo, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.620-4 (June 1983). In Japanese.
A series of studies have been conducted on the effect of retightening, (reloading) on stress relaxation behavior of high temperature bolts used in steam turbines. The results are described of reloading stress relaxation tests made after relaxation to various specific values of residual stress for a 19Cr-9Ni-1.4Mo-1.4W-Nb bolting steel at the test temperature of 650°C. Most of the repeated loadings on the specimens were brought up to rupture. Logarithmic relations between the testing time at each cycle and the number of loadings were analyzed numerically by taking the specific value of residual stress as a parameter. The results confirmed the previous empirical equation. As for rupture behavior, the following three terms, the number of loadings, the accumulated testing time, and the accumulated plastic strain, were expressed by power functions of the specific value of residual stress. From these equations obtained for reloading stress relaxation behavior and rupture, the design curves of retightening characteristics of bolts were presented. (13 refs.)

109463 Study on creep crack growth properties for $2^1/_4$ Cr-1Mo steel. T.Sato, T.Kurumaji, S.Kimura (Kure Res. Lab., Babcock-Hitachi K.K., Kure, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.630-4 (June 1983). In Japanese.
The effect of heat treatment on the creep crack growth properties of $2^1/_4$Cr-1Mo steel was determined and then compared with the creep crack behaviour of actual weld joints. Creep crack growth properties are remarkably changed by heat treatment. The creep crack growth rate increased with decreasing ductility, in the following order. Simulated HAZ>water quenched->normalized-tempered>annealed. The J-da/dt curve on a high ductility condition is different from that on a low ductility condition even for the same steel. Creep cracks advanced in the coarse grain heat affected zone in actual weld joints of 1Cr-$^1/_2$Mo steel. Creep crack resistance is improved by reduction of hardness due to stress relieving. (11 refs.)

109464 Behavior of crack propagation in a low alloy steel under high-temperature rotating bending fatigue. K.Kanazawa, K.Yamaguchi, N.Suzuki, M.Sato, M.Kanao (Nat. Res. Inst. for Metals, Tokyo, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.640-4 (June 1983). In Japanese.
Stepwise *S-N* curves have been obtained at 500°C under rotating bending fatigue tests for the notched specimens of a low alloy steel SCM 435. The behavior of crack propagation under such fatigue conditions was examined, and the reason why such stepwise *S-N* curves and the effect of oxide formed at the crack surface on the crack propagation were discussed. On the fracture surface failed at the longer life side in the stepwise *S-N* curve, a certain region from the root of the notch, designated as the A region, was covered with a thick oxide layer. In the A region, a crack propagated with a very slow rate and the propagation rate scarcely depended on the crack length. By examining the change in compliance under rotating bending conditions, it was clarified that the crack opening level was increased by the oxide formed on the crack surface. (12 refs.)

109465 Effect of strain wave shape on low-cycle fatigue crack propagation of type SUS 304 stainless steel at elevated temperatures. M.Okazaki, F.Shiraiwa, I.Hattori (Dept. of Mech. Engng., Technol., Univ. of Nagaoka, Nagaoka, Japan), T.Koizumi.
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.645-50 (June 1983). In Japanese.
The effect of strain wave shape on the propagation of strain-controlled low cycle fatigue cracks in type SUS 304 stainless steel was investigated at 600 and 700°C. It was found that the rate of crack propagation in the cycle-dependent region was successfully correlated with a range of cyclic J-integral, regardless of strain wave shape, frequency and test temperature. It was also shown that the rate of crack propagation gradually increased from a cycle-dependent type to a time-dependent one as frequency decreased and slow-fast strain wave shape became obvious, and that the ratio of the range of creep J-integral to that of total J-integral was an important factor in such a behavior. Furthermore, the fatigue crack initiation mechanism under strain with slow-fast strain wave shape was studied and it was shown that grain boundary sliding played an important role in it. (16 refs.)

109466 Fatigue life prediction of nickel base superalloy under intermittent strain cycling. T.Okada, T.Horikawa, H.Nakamura, T.Tsunenari, K.Take (Tech. Inst., Kawasaki Heavy Industries Ltd., Akashi, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.651-6 (June 1983). In Japanese.
In order to establish the fatigue life prediction method for gas turbine blades, the fatigue tests are being conducted under the intermittent strain waveform which is composed of cycling of a large pulsating strain and superposed small strain cycling. The results of fatigue tests on Inconel 713 LC under constant amplitude strain cycling, tension hold strain cycling and intermittent strain cycling at 600°C were given. The fatigue lives observed under the intermittent strain cycling were compared with those predicted by using the linear cumulative damage concept. (6 refs.)

109467 Elevated temperature low cycle fatigue strength of forged Ni-base superalloy IN 718. K.Kuwabara, A.Nitta, T.Kitamura (Central Res. Inst. of Electric Power Industry, Komae, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.657-61 (June 1983). In Japanese.
In order to investigate the characteristics of low cycle fatigue strength of a forged Ni-base superalloy IN 718 at elevated temperatures, strain-controlled fatigue tests were carried out on the smooth specimens and load-controlled fatigue crack propagation tests on the notched specimens. As a result, the failure life for the smooth specimen was found to be sensitive to the fracture mode and to decrease by changing from transgranular to intergranular fracture. It was also found that the failure life was independent of the type of straining in compression. The crack propagation rate in the intergranular fracture mode as well as in the transgranular fracture mode was correlated well with the stress intensity factor, which implied the creep fracture under a small scale creep condition. (6 refs.)

109468 A fracture criterion of Inconel 617 under cyclic straining at high temperatures. M.Kitagawa, K.Tamura, A.Ohtomo (Res. Inst., Ishikawajima-Harima Heavy Industries, Co. Ltd., Tokyo, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.662-6 (June 1983). In Japanese.
The materials used in high temperature equipment are often subjected to the cyclic straining at the temperatures where fracture is often controlled by time dependent phenomena. The cyclic fracture at such high temperatures sometimes cannot be evaluated by the conventional creep or creep-fatigue fracture criteria. Therefore, a new fracture criterion utilizing the static and cyclic creep rupture time and static creep rupture ductility is proposed.In the criterion, fracture is considered to occur when the sum of the ductility exhaustion damage (which is proportional to the unidirectionally accumulated strain) and the creep damage (determined by time divided by cyclic creep rupture time) reaches a constant value. The criterion was successfully applied to the life prediction of the inscale fracture model of a high temperature heat exchanger made of Inconel 617 alloy. Furthermore, the strain rate dependency of cyclic life under various saw tooth waves was proved to be explainable by the same criterion if the local strain behaviour was examined. (8 refs.)

109469 Effect of vacuum environment on high temperature low-cycle fatigue properties of Inconel 617. H.Hattori, M.Kitagawa, A.Ohtomo (Res. Inst., Ishikawajima-Harima Heavy Industries Co. Ltd., Tokyo, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.667-71 (June 1983). In Japanese.
A set of strain controlled fatigue tests were carried out at 1000°C in air and vacuum environments. The fatigued specimens were metallographically examined by means of an optical and scanning electron microscopes and electron probe microanalysis.

109470 Effects of frequency and temperature- and strain-waveform on thermal fatigue strength of type 316 stainless steel. T.Tsunenari, T.Horikawa, T.Okada, K.Take, T.Miyashita (Tech. Inst., Kawasaki Heavy Industries Ltd., Akashi, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.672-7 (June 1983). In Japanese.
The effects of frequency and temperature— and strain-waveform on thermal fatigue strength were examined by conducting out-of-phase and in-phase thermal fatigue tests with three kinds of temperature-waveforms (fast heating and fast cooling, slow heating and slow cooling, slow heating and fast cooling) under temperature cycling between 350-650°C and by isothermal low-cycle fatigue tests at 650°C under cyclic frequencies of 0.5~0.39 cpm. The effect of frequency on fatigue life in out-of-phase thermal fatigue was as small as in isothermal low-cycle fatigue, whereas in in-phase thermal fatigue it was much greater and the fatigue life reduction was more remarkable in low frequency. The effect of temperature-and strain-waveform on thermal fatigue life was still smaller than the effect of frequency on out-of-phase thermal fatigue life. The fracture mode of out-of-phase thermal fatigue was the transgranular type even at the lowest frequency tested. (12 refs.)

109471 Thermal fatigue strength of gray cast iron. S.Iwanaga, Y.Sakakibara, T.Miyoshi, K.Saruki (Toyota Central Res. & Dev. Labs. Inc., Aichi, Japan).
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.678-82 (June 1983). In Japanese.
Describes the difference between out-of-phase and in-phase thermal fatigue lives of gray cast iron resulting from the difference in maximum tensile stress between two phases, which is caused by the asymmetry in the stress-strain relation of gray cast iron. Thermal fatigue tests were performed in the temperature range 150~500°C, in which the growth of cast iron was negligibly small, under strain controlled conditions. The life of in-phase thermal fatigue, in which tensile stress appears at the high temperature side, was about 30 times longer than the life of out-of-phase thermal fatigue, in which compressive stress appears at the high temperature side. In the hysteresis loop of the first cycle, the maximum tensile stress in in-phase thermal fatigue was smaller than that in out-of-phase thermal fatigue. (7 refs.)

109472 Effect of low temperatures on the low cycle fatigue of low carbon steel. J.Polak, P.Liskutin, J.Helesic (CSAV, Brno, Czechoslovakia).
Kovove Mater. (Czechoslovakia), vol.21, no.4, p.425-38 (1983). In Czech.
The cyclic plastic stress-strain response and fatigue life of low carbon steel at temperatures ranging from room temperature down to 133K were studied. Cyclic straining with constant strain rate and constant plastic strain amplitude was applied. The effective stress component increases considerably while the internal stress component decreases slightly at low temperatures. This is in accord with the increase of the parameter characterising the average size of the dislocation substructure at low temperatures. The fatigue life curve changes with decreasing temperatures both in Manson-Coffin's and Wohler's plots but it was found to be a unique function of the average energy dissipated in one cycle. (11 refs.)

109473 High temperature hardness of tungsten carbide. Minyoung Lee (Corporate Res. & Dev., General Electric Co., Schenectady, NY, USA).
Metall. Trans. A (USA), vol.14A, no.8, p.1625-9 (Aug. 1983).
The effect of crystallographic orientation and test temperature on hardness of WC single crystals was investigated along with the hot hardness of polycrystalline tungsten carbide. Also investigated was the effect of carbide grain size and the amount of binder phase on the hot hardness of some cemented tungsten carbides. The hot hardness of single crystal WC on all major crystallographic orientations evaluated decreases very rapidly for increasing temperature, and the single crystal hardness on its hardest orientation is only about half on the polycrystalline material depending on the test temperature. Because of its polycrystalline character, some cobalt bonded cemented tungsten carbides can be harder than single crystal WC over some intermediate temperature range. (7 refs.)

109474 Effects of load ratio and temperature on the near-threshold fatigue crack propagation behavior in a CrMoV steel. P.K.Liaw, A.Saxena (Dept. of Metall., Westinghouse Res. & Dev. Center, Pittsburgh, PA, USA), V.P.Swaminathan, T.T.Shih.
Metall. Trans. A (USA), vol.14A, no.8, p.1631-40 (Aug. 1983).
The influence of temperature in the range of 24 to 260°C and load ratio on the near-threshold fatigue crack growth rate behavior of a CrMoV steel was characterized. At all temperatures investigated, the threshold stress intensity range, ΔK_{th}, for fatigue crack growth decreased with increasing load ratio. The near-threshold crack growth rates increased significantly at 149°C when compared with the rates at room temperature. However, the crack growth rates at 260°C were comparable to those at 149°C. These observations are rationalized in terms of the concepts of roughness and oxide-induced crack closure. Extensive fracture surface characterization using SEM, oxide thickness measurements by Auger spectroscopy, and roughness measurements by light-section-microscopy were conducted to substantiate the explanations. (36 refs.)

109475 Crack propagation of steels during low cycle thermal-mechanical and isothermal fatigue at elevated temperatures. M.Okazaki (Fculty of Engng., Technol. Univ. of Nagaoka, Nagaoka, Japan), T.Koizumi.
Metall. Trans. A (USA), vol.14A, no.8, p.1641-8 (Aug. 1983).
The surface and through crack propagation of three high temperature steels in low cycle thermal-mechanical and isothermal fatigue at elevated temperatures was investigated. The rate of crack propagation obtained was correlated with the range of cyclic J-integral, ΔJ_f. It was found that there is a linear relationship on a log-log plot regardless of materials, test conditions, and crack configurations. Furthermore, fatigue life predicted by integrating the equation of crack propagation was compared with experimental results. (32 refs.)

109476 Effect of strain wave shape on low-cycle fatigue crack propagation of SUS 304 stainless steel at elevated temperatures. M.Okazaki, I.Hattori, F.Shiraiwa (Dept. of Mech. Engng., Technol. Univ. of Nagaoka, Nagaoka, Japan), T.Koizumi.
Metall. Trans. A (USA), vol.14A, no.8, p.1649-59 (Aug. 1983).
Effect of strain wave shape on strain-controlled low-cycle fatigue crack propagation of SUS 304 stainless steel was investigated at 600 and 700°C. It was found that the rate of crack propagation in a cycle-dependent region was successfuly correlated with the range of cyclic J-integral, ΔJ_f, regardless of the strain wave shape, frequency, and test temperature. It was also shown that the rate of crack propagation gradually increased from cycle dependent curve to time-dependent one with decreasing frequency and slow-fast strain wave shape, and that one of the factors governing the rate of crack propagation in such a region was the ratio of the range of creep J-integral to that of total J-integral, $\triangle J_c/\triangle J_T$. Based on the results thus obtained, an interaction damage rule proposed semi-empirically was interpreted, with regard to crack propagation. Furthermore, fatigue crack initiation mechanism in slow-fast strain wave shape was studied, and it was shown that gain boundary sliding took an important role in it. (29 refs.)

109477 Anisotropic embrittlement in high-hardness ESR 4340 steel forgings. G.B.Olson (MIT, Cambridge, MA, USA), A.A.Anctil, T.S.DeSisto, E.B.Kula.
Metall. Trans. A (USA), vol.14A, no.8, p.1661-9 (Aug. 1983).
ESR 4340 steel forgings tempered to a hardness of HRC 55 exhibit a severe loss of tensile ductility in the short transverse direction which is strain-rate and humidity dependent. The anisotropy is also reflected in blunt-notch Charpy impact energy, but is absent in the sharp-crack fracture toughness. Brittle behavior is associated with regions of smooth intergranular fracture which are aligned with microstructural banding. Scanning Auger microprobe analysis indicates some intergranular segregation of phosphorus and sulfur in these regions. The anisotropic embrittlement is attributed to an interaction of nonequilibrium segregation on solidification with local equilibrium segregation at grain boundaries during austenitizing. This produces defective regions of enhanced intergranular impurity segregation which are oriented during forging. The regions are prone to brittle fracture under impact conditions and abnormal sensitivity to environmental attack during low strain-rate deformation. A relatively sparse distribution of these defects (~ 10 cm^{-3}) accounts for the discrepancy between smooth bar and blunt-notch tests vs. sharp-crack tests. Isotropic properties are restored by homogenization treatment. For application of these steels at extreme hardness levels, homogenization treatment is essential. (20 refs.)

109478 The effect of grain size on fatigue growth of short cracks. A.K.Zurek, M.R.James, W.L.Morris (Rockwell Internat. Sci. Center, Thousand Oaks, CA, USA).
Metall. Trans. A (USA), vol.14A, no.8, p.1697-705 (Aug. 1983).
The influence of alloy grain size on growth rates of surface cracks 20 to 500 μm in length was studied in Al 7075-T6 specimens prepared in 12 and 130 μm grain sizes. Grain boundaries temporarily interrupt the propagation of cracks shorter than several grain diameters in length. Linear elastic fracture mechanics is inadequate to describe resulting average growth rates which must instead be characterized as a function of cyclic stress amplitude, σ_a, and alloy grain size as well as stress intensity range, ΔK. These observations are rationalized using two models, one that relates crack closure stress to alloy grain size. In addition, growth rates were found to be faster in fully reversed loading than in tension-tension loading, especially in the large grained material. Evidence is presented to demonstrate that this is a consequence of the fatigue induced development of a compressive residual surface stress during tension-tension loading. (23 refs.)

109479 Hydrogen pressure dependence of the fracture mode transition in nickel. R.H.Jones, S.M.Bruemmer, M.T.Thomas, D.R.Baer (Battelle-Northwest Lab., Richland, WA, USA).
Metall. Trans. A (USA), vol.14A, no.8, p.1729-36 (Aug. 1983).
A relationship between fracture mode, grain boundary composition, and hydrogen pressure has been determined for nickel straining electrode samples tested at cathodic potentials. This relationship can be expressed as $C_S^* \alpha P_{H2}^{-n}$ where C_S^* is the critical grain boundary sulfur concentration corresponding to 50% transgranular and 50% intergranular fracture and P_{H2} is the hydrogen pressure. The value of n was found to be between 0.34 and 0.9. This expression was derived by relating C_S^* to the hydrogen overpotential with the Nernst equation. At a cathodic test potential of -0.3 V (SCE), C_S^* was equal to 0.20 monolayers of sulfur and at higher cathodic potentials of higher hydrogen pressures, C_S^* decreased such that at -0.72 V (SCE) C_S^* was equal to 0.045 monolayers of sulfur. The inverse hydrogen pressure dependence observed with cathodic hydrogen is similar to that for the hydrogen permeation rate or a critical hydrogen concentration derived by Gerberich et al. (1975) for gaseous hydrogen. (22 refs.)

109480 Effect of stress biaxiality of the fatigue crack growth rate of a mild steel. S.Harada, T.Endo (Dept. of Mech. Engng., Kyushu Inst. of Technol., Kitakyushu, Japan).
Mem. Kyushu Inst. Technol. Eng. (Japan), no.13, p.11-18 (March 1983).
Fatigue crack growth under multiaxial loading is of importance in engineering practice. In order to examine the effect of stress biaxiality on the fatigue crack growth rate, torsional (biaxial) and uniaxial zero-tension fatigue crack propagation tests were carried out on a mild steel. The experimental results showed that the stress bixiality gives a different effect on the crack growth rate depending on the loading condition. Estimation of the stress biaxiality effect was done by focusing attention on the crack tip plastic zone size. (21 refs.)

109481 Structure and properties of low-carbon steel alloyed with boron and copper. Ya.N.Malinochka, G.Z.Koval'chuk, V.N.Yarmosh (Inst. of Ferrous Metall., Dnepropetrovsk, USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.760-5 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.10-14 (Nov. 1982).
It was found that adding as much as 0.5% Cu to steel microalloyed with boron (as much as 0.003%) increases the solubility of boron in austenite and prevents precipitation of brittle boron-containing phase in austenite grain boundaries. Adding copper to steel with boron increases the stability of supercooled austenite somewhat and has no negative effect on the hardenability of the steel. After heat treatment, steel with boron and copper has higher values of strength and especially fracture toughness as compared with steel and boron but without copper. The ductility of the steel with both additions is fairly high and approaches that of unalloyed steel as the tempering temperature is raised. Adding copper lowers the ductile-brittle transition temperature of steel containing boron. (14 refs.)

109482 Microstructure and mechanical properties of 20GTL steel after heat treatment using various cycles. A.A.Zhukov, F.A.Bekerman, A.N.Kharitonov, A.I.Bondarev, A.N.Platonov (Bryansk Inst. for Transport Machinery Building, Bryansk, USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.766-71 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.15-19 (Nov. 1982).
It is concluded that steel modified with titanium and having a quite high residual aluminum content is relatively insensitive to overheating. 20GTL steel may be austenitized at 920 and even at 970°C. Overheating at 1050°C does not lead to a significant reduction in its mechanical properties. The impact strength of the normalized steel (including at -60°C) is more sensitive to underheating than to overheating. The negative influence of the pearlite network in the structure of 20GTL steel is revealed in a reduction in impact strength at $+20$ and -60°C. Hardening and tempering of cast steel make it possible to completely homogenize its microstructure and significantly increase the strength properties without a significant reduction in ductility. However, the impact strength at $+20$ and -60°C does not increase. (4 refs.)

109483 Structure and properties of steel for high-pressure vessels. M.B.Balakhovskaya, L.V.Nadtsyna, L.N.Davlyatova (All-Union Sci.-Res. Inst. for Heat Engng., USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.772-4 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.19-21 (Nov. 1982).
It was found that the structure of 16GNMA steel in the normalized condition consists of ferrite and bainite or of upper bainite. The steel with the bainitic structure is characterized by a higher thermal fatigue resistance than that with a ferritic-bainitic structure. When together with thermal fatigue the metal is subjected to the action of shut-down (acid) corrosion, the steel with the bainitic structure is less reliable. Both in the original (after normalizing and tempering) and the aged conditions 16GNMA steel has sufficiently high resistance to brittle fracture. (no refs.)

109484 Influence of carbon vacuum deoxidation on the properties of 34KhN1M steel. P.V.Sklyuev, V.S.Gulyakov, O.A.Polzunov, V.E.Sokolov (Ural Heavy Machinery Plant Production Union, USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.774-7 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.21-2 (Nov. 1982).
In carbon vacuum deoxidation by the method of pouring from ladle to ladle and subsequent teeming in air there was an increase in impact strength and ductility, a decrease in the tendency toward temper embrittlement, and a reduction in the brittle-ductile transformation temperature. (11 refs.)

109485 Effect of structure on the type of fracture of titanium alloy VT3-1. N.Z.Pertsovksii, M.Ya.Brun, N.M.Semenova.
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.853-9 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.12, p.45-7 (Dec. 1982).
The effect of the structural parameters on the fracture mode of alloy VT3-1 (6.3% Al, 2.3% Mo, 1.6% Cr, 0.4% Fe) was studied with different types of tests. The samples were prepared from a rolled bar 20 mm in diameter in which final deformation occurred in the $\alpha+\beta$ range. For samples intended for fracture toughness tests forged disks 400 mm in diameter were used after deformation under various conditions with heating in the β and $\alpha+\beta$ ranges. The mechanical properties were tested with standard samples for tensile tests, bending tests, and off-centered tensile tests in samples with a thickness of 20 mm. The samples with an equiaxed structure had the highest ductility and lowest values of α_T and K_{Ic}. For samples with a lamellar structure the ductility decreased with increasing diameter of the original β grains and decreasing size of the α colonies. Thinning of α platelets caused the tensile strength to increase, but the ductility and fracture toughness to decrease. (8 refs.)

109486 Size and mechanical properties of craze zones at propagating crack tips in poly(methyl methacrylate) during fatigue loading. W.Doll, L.Konczol, M.G.Schinker (Fraunhofer-Inst. fur Werkstoffmech., Freiburg, Germany).
Polymer (GB), vol.24, no.9, p.1213-19 (Sept. 1983).
In specimens of high molecular weight poly(methyl methacrylate) the microregion at the crack tip has been investigated during fatigue crack propagation by applying the optical interference method in a specially constructed experimental set-up. Thus, in the frequency range of 0.4 to 50 Hz the size and contour of the craze zone were directly measured at upper and

lower load of the cycles. In contrast to previous assumptions it is established that the maximum craze width at the crack tip and hence the maximum length of stretched fibrils increases strongly with crack propagation rate. The directly measured craze data and also the material parameters indirectly derived by the aid of the Dugdale model are related to those data which have been measured during continuous crack propagation under quasi-static tensile load. The spacings of the fatigue striations on the fracture surfaces are compared with the lengths of the craze zones. (28 refs.)

109487 Quantitative morphology analysis for establishing correlations between morphology and properties of impact resistant PVC. G.Leps, J.Sachse, J.Bohse, R.Stephan (Tech. Hochschule 'Carl Schorlemmer', Leuna-Merseburg, Merseburg, Germany).
Prakt. Metallogr. (Germany), vol.20, no.6, p.297-305 (June 1983). In German, English.
In order to establish quantitative correlations between morphology and properties of notch impact resistant P(EVA-g-VC) systems, the following morphological parameters were determined from TEM and SEM micrographs, respectively: volume ratio of phases; content of PVC primary particles; continuity of EVA phase; coefficient of variation of continuity of EVA phase; and elongation and deformation of PVC primary particles. (12 refs.)

109488 Fracture of ceramics under multiaxial stresses. A statistical approach applied to bending tests. J.Lamon (Centre des Materiaux, Ecole Nat. Superieure des Mines de Paris, Evry, France).
Rev. Int. Hautes Temp. & Refract. (France), vol.19, no.3, p.171-83 (1982). In French.
A general approach for the statistical analysis of fracture under multiaxial stress states has been evaluated for a fracture criterion based upon recent concepts of non-coplanar crack extension. The resultant failure expressions have been applied to bend tests and used to interpret experimental results obtained with porcelain cylinders. Implications for the interpretation of bending tests and some important trends in the failure strength with specimen size are discussed. (12 refs.)

109489 Acoustic emission study of microcracking damage in polycrystalline $(V,Cr)_2O_3$ during thermal cycling of the near-room-temperature phase transition. V.Boutinard Rouelle-Rossier, C.Carry (Lab. de Ceramique EPF-Lausanne, Switzerland).
Rev. Int. Hautes Temp. & Refract. (France), vol.19, no.3, p.255-6 (1982). In French. (no refs.)

109490 Porosity effects on thermal shock resistance of ceramics. J.C.Glandus, P.Boch (ENS CI-CNRS, Limoges, France).
Rev. Int. Hautes Temp. & Refract. (France), vol.19, no.3, p.257-65 (1982). In French.
The porosity dependence of thermal shock resistance of two nitride ceramic materials is studied. It is shown, that although the use of thermoelastic analysis leads to an expected decrease of fracture resistance, this parameter is not systematically lowered by an increase in porosity. On the contrary, one observes that increasing porosity gives rise to an improvement of damage resistance. The good agreement between these observations and many bibliographical data allows the generalisation of the present results. (21 refs.)

109491 Cold brittleness of constructional low-carbons steel produced from metallised raw material. L.V.Samoylenko, A.I.Ivanov, G.K.Volkova, P.Ya.Dovzhuk.
Russ. Metall. (GB), no.1, p.106-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.120-3 (1982).
Reduction of the coloured impurities, formation of a more finely-dispersed structure, and refining of the subgrain structure in low-carbon constructional steel from heavy metallised charges cause a lowering of the critical embrittlement temperature to −100°C. (12 refs.)

109492 Effect of deformation and heat treatment on phase transitions and properties of titanium alloys. L.K.Dolinskaya, A.F.Matveyenko, Yu.V.Rodionov.
Russ. Metall. (GB), no.1, p.111-14 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.126-30 (1982).
The dependence of the phase transformations and mechanical properties of the VT22 and VT22M titanium alloys on deformation and heat treatment was examined. The high strength of both alloys was found to be associated with the quantitative ratio of the α and β phases but was determined mainly by the structural condition of the alloys. (4 refs.)

109493 Use of the parameters of fracture microrelief for evaluation of the performance of structural materials. L.I.Maslov, O.G.Zamolodchikov, S.A.Kunavin.
Russ. Metall. (GB), no.1, p.168-71 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.196-201 (1982).
Attention is given to one of the possible parameters in the evaluation of local fracture based on an analysis of the energy of local plastic deformation in the fracture of materials by the separation mechanism (microvoid coalescence). (11 refs.)

109494 Examination of the temper brittleness of quenched and tempered low-alloy steels. V.M.Goritskiy, L.I.Gladshteyn, G.R.Shneyderov.
Russ. Metall. (GB), no.2, p.135-40 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.150-6 (1982).
Investigations were conducted into the effect of alloying with molybdenum, phosphorus and vanadium with nitrogen on the structure and susceptibility to thermal embrittlement of low-alloy quenched and tempered steel 10KhSND. Examination by the methods of quantitative fractography shows that in thermal embrittlement conditions, the propagation of cracks in 10KhSND steel takes place mainly along the boundaries of large subgrains and prior martensite packets. In the given compositions of 10KhSND steel, the development of thermal embrittlement is accompanied by a marked increase in the size of intersubgrain fracture facets d_f on the fracture surface; the degree of increase of d_f depends on the composition of the steel and increases to the largest extent for steel alloyed with vanadium and nitrogen. The thermal embrittlement of the quenched and tempered steels is closely linked with the critical density of large ($\sim$0.1 μ) cementite-type particles at the subgrain boundaries. (9 refs.)

109495 Fracture in cryogenic steel (9% Ni) under low-temperature low-cycle fatigue. V.A.Duryagin, A.B.Kuslitskiy, I.V.Kokotaylo, K.B.Katsov.
Russ. Metall. (GB), no.2, p.141-3 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.157-9 (1982).
The features of deformation and fracture of 9% nickel steel (0.03 C, 0.56 Mn, 0.33 Si, 9.52 Ni, 0.05 Al, 0.28 Mo, 0.03 Cr, 0.008 S) were examined under conditions of low-temperature small-cycle fatigue in pure (nonzero) bending. The zone of fatigue crack propagation was found to decrease, whilst the rate of growth of the cracks increased, as the test temperature is reduced. Whilst at room temperature the low-cycle fatigue strength of cryogenic steel is limited by the duration of this stage of crack propagation, at low temperatures the predominant factor is the duration of the stage of crack formation. (3 refs.)

109496 Regularities in the formation of the shape of scratches on tungsten monocrystals. V.V.Dorokhov, A.Ya.Shvartser.
Russ. Metall. (GB), no.2, p.143-7 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.159-64 (1982).
An effort was made to elucidate some specific features of interaction of a single abrasive (indentor) with a BCC metal by studying the influence of the crystallographic orientation on the processes of formation of the shape of the scratches. The process is characterised by the presence of directions of a predominant flow of the metal in front of moving indentor. On the (001) face the metal is squeezed out along the <110>, on the (011) face along the <100>, on the face (111)−along the <11$\bar{2}$> direction. The displacement of the metal upwards in front of the moving indentor occurs along the 112 slip planes. The anisotropy during scratching of tungsten crystals is associated with the orientation of active slip planes {112} and with the positioning of twinning directions in these planes. (9 refs.)

109497 Dependence of the hardness of α'-uranium alloys on the factor of dimensional non-correspondence. L.M.Gomozov.
Russ. Metall. (GB), no.2, p.148-50 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.165-7 (1982).
The value of dHV/dc (c-concentration) for α'-alloys of uranium with Cr, V, Mo, Zr and Nb was experimentally determined. A comparison of the increase in hardness (ΔHV) as a measure of dissolution hardening and of the factor of dimensional non-correspondence of atoms of uranium and alloying elements (η) yields the relationship $\Delta HV \sim \eta^{1.46}$. The dissolution hardening of binary α'-solid solutions of uranium is more intensive than hardening of metals with more symmetrical crystal structures. Apparently, this is due to the fact that, together with dimensional distortions, the distortions of symmetry of the lattice of α-uranium appear, which possess special fd-electron bonds. (8 refs.)

109498 Load frequency dependence in fatigue life of nitrided steel. K.Ishizaki, L.H.Corredor, G.O.Fior (Dept. of Materials Sci., Univ. Simon Bolivar, Caracas, Venezuela).
Scr. Metall. (USA), vol.17, no.8, p.979-81 (Aug. 1983).
At frequencies lower than about 5 Hz, the fatigue life of nitrided steel is greatly decreased with respect to fatigue life at frequencies higher than 5 Hz. The shortening fatigue life at low frequencies may be due to enhanced nitrogen diffusion caused by the Snoek effect. (11 refs.)

109499 Fatigue crack initiation from a notch tip under a cyclic compressive load. Wu-Yang Chu, Chin-Mei Hsiao, Lian-Jiang Jin (Dept. of Metal Phys., Beijing Univ. of Iron & Steel Technol., Beijing, China), Tian-Hua Liu.
Scr. Metall. (USA), vol.17, no.8, p.993-6 (Aug. 1983).
It was found that a fatigue crack could initiate from a notch under a cyclic compressive load but the threshold value was four times as large as that under a cyclic tensile load. The fatigue crack would not propagate under a cyclic compressive load after it grew to a certain size. If the minimum cyclic load was near zero, the threshold value of crack initiation under cyclic compressive stress decreased greatly and the fatigue crack continued to propagate. (1 ref.)

109500 Low-cycle fatigue of titanium alloys promising for cryogenic generator construction. V.A.Strizhalo, A.I.Zinchenko, A.A.Chernyi, N.A.Grekov, G.I.Arkovenko (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.8, p.1006-11 (Aug. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.8, p.10-15 (Aug. 1982).
The results of low-cycle fatigue studies of the Ti alloys PT3V and 19 are presented. The loading conditions and temperatures for the tests were chosen with allowance for possible service conditions of cryogenic generator rotors: a change in load according to a pulsating cycle at low frequency ($\sim$1.5-2 cycles/min) and constant temperature. The tests were conducted at three temperatures: 293, 77, and 4.2K (the tests at 293 K were conducted under room conditions in air, while the tests at 77 and 4.2K were performed in liquid nitrogen or helium). (3 refs.)

109501 Evaluation methods of residual fatigue life of metallic materials. V.I.Kovpak (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian, SSR).
Strength Mater. (USA), vol.14, no.8, p.1030-4 (Aug. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.8, p.31-4 (Aug. 1982).
Discusses the problems involved in the prediction of the residual life of metallic materials, which is the margin by which the structural elements can be extended after their calculated life has been spent. (13 refs.)

109502 Constructional thermal-fatigue strength of R2M rotor steel. M.G.Kabelevskii, L.I.Stolyarova, G.G.Medekshas, P.T.Krasauskas (Central Heavy Machinery Res. Inst., Moscow, USSR).
Strength Mater. (USA), vol.14, no.8, p.1048-54 (Aug. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.8, p.47-52 (Aug. 1982).
The authors examined the production and growth of thermal fatigue cracks and determined the thermal fatigue strength characteristics of R2M rotor steel. These characteristics include the following: the relationship between the deformation and the number of cycles to the production of a crack, the parameter representing the sensitivity to stress concentrations, and the dependence of the crack propagation speed on the magnitude of the stress-intensity coefficient. The experiments were performed with model disks of diameter 300 mm and thickness 40 mm with eight axial slots of depth 10 mm on the circumference. Each pair of slots had a radius of curvature of 0.25, 1, 2.5, or 7 mm. The differences in sharpness of the notches meant that the material could be tested at theoretical stress-concentration coefficients ranging from 3.4 to 14 simultaneously. (17 refs.)

109503 Effect of the dimensions of specimens on the crack resistance of creep-resisting hull steels. V.T.Troshchenko, V.V.Pokrovskii, V.G.Kaplunenko, P.V.Yasnii, G.P.Karzov, B.T.Timofeev, V.P.Leonov (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.10, p.1289-98 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.3-11 (Oct. 1982). [received: Sept. 1983]
The authors investigated the effect of the scale factor on the crack resistance of the hull steels 15Kh2MFA, 15Kh2NMFA (I), and 15Kb2NMFA (II). Increased thickness of specimens was found to lead to reduced rate of fatigue crack growth on the first section of the diagram of fatigue failure and to increased value of K_{th} of the investigated steels at 293K. Increased thickness of the specimen practically did not cause a change of the rate of fatigue crack growth on the Paris section, but it increased the characteristics K_{fc} and K_Q of the investigated steels under cyclic and static loading, respectively. It is concluded that the effect of the scale on the characteristics of fracture toughness of structural steels is apparently connected with the proneness of the material to strain-hardening. (34 refs.)

109504 Fatigue damage to pseudo-α-titanium alloy in the 10-33-Hz frequency range. A.Ya.Krasovskii, Yu.N.Petrov, G.N.Nadezhdin, L.E.Matokhnyuk, V.L.Svechnikov, T.Ya.Yakovleva (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).

Strength Mater. (USA), vol.14, no.10, p.1320-3 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.30-4 (Oct. 1982). [received: Sept. 1983]

The results of tests of a pseudo-α-titanium alloy VT18U at frequencies of 30 and 300 Hz and 10 kHz are used to study the evolution of its dislocation structure during fatigue damage accumulation. The fatigue tests were conducted on smooth specimens with a working diameter of 7 mm. The test results provide evidence of an increase in endurance and endurance limit with an increase in loading frequency. This effect is connected with the fact that given identical stress amplitudes the level of inelastic strain on which fatigue damage accumulation depends will be greater in the case of low-frequency loading. At high frequencies the process of plastic strain cannot be completed to the same degree as at low frequencies and damage to the material is less. (17 refs.)

109505 Effect of the form and size of a fatigue crack on the fatigue fracture toughness of titanium alloy VT9. N.D.Bega (Inst. of Problems of Materials Sci., Acad. of Sci., Kiev, Ukrainian SSR).

Strength Mater. (USA), vol.14, no.10, p.1324-6 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.34-7 (Oct. 1982). [received: Sept. 1983]

The material studied was titanium alloy VT9 in the $\alpha+\beta$ state, heat-treated as follows: annealing at 1223K for 60 min, subsequent cooling in air to 803K, holding for 6 h. The yield point was 1020 MPa, while the ultimate strength was 1120 MPa. The smooth cylindrical specimens had a working length of 30 mm and diameter of 10 mm. From results it is concluded that in the region σ_{max} near the yield point, the plastic strain accumulated to fracture during cyclic loading creates conditions for structural changes in alloy VT9 and is the main reason for the sharp reduction in its fatigue fracture toughness. Further studies will be required to obtain a consistent physical model of this effect. (5 refs.)

109506 Zones of elastic deformation under the surface of impact fracture of steel 45. L.R.Botvina, G.V.Klevtsov, Yu.S.Gladilov (A.A. Baikov Inst. of Metall., Acad. of Sci., Moscow, USSR).

Strength Mater. (USA), vol.14, no.10, p.1348-52 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.55-9 (Oct. 1982). [received: Sept. 1983]

The presence of two zones of plastic deformation under the fracture surface in impact loading was revealed. The temperature relationship of the depth and degree of plastic deformation of the material in these zones in the brittle-ductile transformation area was investigated. It is concluded that the appearance of the weakly deformed macrozone is related to reaching the critical degree of plastic deformation on the fracture surface ϵ_c at which the fibrous constituent appears in the fracture. The temperature of occurrence of this zone corresponds to the lower brittle-ductile transition temperature; the temperature of reaching the critical degree of plastic deformation in this zone ϵ_y^{max} corresponds to the upper brittle-ductile transition temperature. (12 refs.)

109507 Evaluating the crack resistance of tungsten at high temperatures. A.V.Babak (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).

Strength Mater. (USA), vol.14, no.10, p.1389-91 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.89-91 (Oct. 1982). [received: Sept. 1983]

The influence of temperature on the crack resistance of tungsten was studied. The investigation was made on standard 6-mm-thick type VR samples. The samples were tested in off-center tension in the 20-2000°C temperature range. During the crack resistance tests of the samples, tensile curves were drawn to load P vs. displacement V_t coordinates, by treatment of which, using the standard scant method, the value of the critical load for start of crack advance P_Q was determined. The stress intensity factor K_Q was used as the crack resistance parameter. (9 refs.)

109508 Behavior of shells of various types in internal explosive loading. A.I.Belov, V.E.Klapovskii, V.N.Mineev, A.I.Nazarov, V.I.Nelin, M.N.Niklonskii (Central Sci.-Res. Inst. of Sci. & Tech. Information, Moscow, USSR).

Strength Mater. (USA), vol.14, no.10, p.1417-19 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.113-15 (Oct. 1982). [received: Sept. 1983]

Comparative experimental investigations were carried out into the dynamic strains and fracture of solid and multilayer shells subjected to internal loading with a pressure pulse. The shells were made of steel Kh18N9T. The multilayer shell was assembled from two coaxial cylinders with the gap between them filled with water. The total thickness of the shells was selected similar to the thickness of the solid shell. Pulsed loading was generated by means of an axisymmetric explosion of a condensed substance (ES) in air. (3 refs.)

109509 Fractographic study on fatigue fracture of some heat-treated steels for lower da/dN values. C.Masuda, S.Nishijima.

Trans. Natl. Res. Inst. Met. (Japan), vol.25, no.2, p.79-86 (June 1983).

Microfractographic aspects of fatigue fracture were examined in relation to the strength level of material and the macrocrack propagation rate, da/dN, with a particular emphasis on the low da/dN range. The materials investigated were heat-treated carbon and low alloy steels characterized by different levels of Vickers hardness (HV=140, 330, 480, and 780). Fatigue tests were conducted under repeated tensile loads. For low da/dN values (<100 nm/cycle), the fatigue fracture surface exhibited a certain amount of intergranular facets, except for the material of HV330. The coverage of intergranular facet was variable depending upon the da/dN level, but was found to take a maximum value when the size of cyclic plastic zone at the crack tip was nearly equal to the size of ferritic grains (steel of HV 140), or prior austenitic grains (steel of HV 480). (6 refs.)

109510 Possible mechanism for embrittlement of Zircaloy by molybdenum and tungsten. R.Kohli (Nuclear Technol. Div., Battelle Columbus Labs., Columbus, OH, USA).

Z. Metallkd. (Germany), vol.74, no.8, p.494-5 (Aug. 1983). In German.

The tensile properties of Zircaloy have been measured after long-term annealing at 623 and 973K in the presence of molybdenum and tungsten powders. The specimens were severely embrittled with total elongation values in the range of 0.2 to 6%. Embrittlement is attributed to the presence of intermetallic phases with corresponding microstructural changes in the specimens. (8 refs.)

109511 Development of the minima in elongation in time-to-rupture creep tests of low alloy steels. G.Hofer (Kraftwerk Union Erlangen, Erlangen, Germany).

Z. Metallkd. (Germany), vol.74, no.8, p.513-20 (Aug. 1983). In German.

A number of low alloy fine grained structural steels show temperature-dependent minima of elongation in time-to-rupture creep tests. The creep behaviour of the superheated and quenched coarse-grained steel 20 MnMoNi 55 (ASTM A 508 Cl.3) was investigated in the temperature range between 550 and 650°C. Tempering in this region improves the elongation at fracture and with that the toughness of the material. With an analysis of the creep behaviour and with instrumented Charpy impact tests it was shown that the minima in the elongation versus time-to-rupture curves are caused by creep processes and not by temper embrittlement. (18 refs.)

109512 Joint exercise to compare fatigue crack growth data obtained on type 304/316 stainless steel. K.Krompholz, G.J.Lloyd, P.Petrequin.

Report EUR 8502 EN, Comm. European Communities, Luxembourg (1983), 37 pp. Contract RAP-013(80) D.

The Activity Group 3 'Materials' of the Working Group on Codes and Standards of the Fast Reactor Co-ordinating Committee has set itself the task of comparing fatigue crack growth data obtained on type 304/316 ss, which are used as structural materials in fast reactor applications in the European Community. The objectives therefore were to compile the available data which reflect the influence of parameters like, for example, frequency, stress ratio, environmental impact etc. in a unified correlation of fatigue crack growth vs. stress intensity factor amplitude; to quantify, if possible, the effect of these parameters on fatigue crack growth and to identify whether the two kinds of steels show differences in fatigue crack growth under comparable conditions.

109513 Study of low-cycle fatigue behaviour of steels at high temperature. A.Origoni, V.Mandorini.

Report EUR 6497 EN, Comm. European Communities, Luxembourg (1982), 84 pp. Contract 6210.KD/4/401.

Creep and low-cycle fatigue tests have been carried out on 2 1/4 Cr 1 Mo steel normalized and tempered, at the temperature of 550°C. Creep rupture times found are very close to those determined, on the same material, in another ECSC research. Low-cycle fatigue tests have shown that elastic and plastic terms of imposed deformation are very well represented by straight lines on a double-log plot versus a parameter N_{of} relative to the useful specimen life. Moreover it was found that the frequency effect on the number of cycles to rupture becomes appreciable near 0.1 c/m and it is the more evident the less is the amplitude. All the specimens have shown a transgranular fracture. Finally a series of combined creep low-cycle fatigue tests interpreted in accordance with the summation of damage fractions attributable to creep and fatigue has shown that, in the experimental conditions, a strengthening mechanism exists for 2 1/4 Cr 1 Mo steel, resulting from the interaction of creep and fatigue phenomena.

109514 Fatigue crack growth and fracture resistance of steels in high-pressure hydrogen environments. A.H.Priest.

Report EUR 8191 EN, Comm. European Communities, Luxembourg (1983), 47 pp. Contract EHC-(1)42-012-81 UK(H).

Presents a review of information and data available from the past British Steel Corporation (BSC) research programmes concerned with the influence of high pressure hydrogen on the properties of steels used for gas containment. An evaluation has been made of the effects of hydrogen pressure and cyclic frequency on the fatigue properties of eight steels, most of which are currently used in the manufacture of gas cylinders. The evaluation has included CrMo and CMn types of steels and material with strength levels close to the bottom and top of the currently specified range. The results indicate a marked influence of hydrogen pressure on the fatigue behaviour of all eight steels. At hydrogen pressures of 150 bar and above even the most 'resistant' steel shows a sixteen-fold increase in fatigue crack growth rate when compared with data obtained in nitrogen gas at a similar pressure. The cyclic frequency has also been observed to influence the fatigue behaviour in a smaller, but still significant, manner. In general the fatigue crack growth rates increase as the frequency is reduced, with the most marked acceleration produced as the frequency drops from 10 to 1 Hz. In CrMo steels the greatest resistance to hydrogen accelerated fatigue crack growth was exhibited by material with a tempered martensite microstructure containing a uniform distribution of fine carbide precipitates. (13 refs.)

109515 Comportement en fatigue d'aciers a haute limite d'elasticite (Fatigue behaviour of steels with high elastic limit). C.Maillard-Salin, H.P.Lieurade.

Report EUR 8060 FR, Comm. European Communities, Luxembourg (1983), 83 pp. In French. Contract 7210.KD/303.

Low-cycle fatigue tests are carried out on different types of butt joints in structural steels. The used joints are welded with manual welding, with MAG welding or with submerged arc welding. Different surface conditions (as rolled or ground) are tested. From the results of tests conducted under total strain amplitude control, strain amplitude versus life curves are plotted. Several experimental parameters characterizing the notch acuity of the different specimens tested are derived using the test data. For this derivation characteristics of the tested specimens are compared with reference characteristics determined on ground specimens. The used reference characteristics correspond to a metal having the same hardness as the crack initiation location. The influence of different parameters is discussed particularly the dimensions effect, notch effect (surface conditions, bead geometry) and the role of microstructure (heat treatment). (10 refs.)

109516 The influence of critical manufacturing variables upon fatigue life of springs. L.Stankowski, J.Warner (Allen-Bradley Co., Milwaukee, WI, USA).

Proceedings of the 31st Relay Conference, Stillwater, OK, USA, 26-27 April 1983 (Elkhart, IN, USA: Nat. Assoc. Relay Manuf. 1983), p.1/1-7

Allen-Bradley Company manufactures numerous devices for use in a corrosive environment that incorporate springs of various shapes and sizes. These springs, with their expected reliability, are often made of stainless steel. This report discusses the relationship of surface texture of stainless steel springs to fatigue life and shows that rough surface texture is a deciding factor in premature fatigue failures. 109517 The amorphous phase and surface mechanical properties of 304 stainless steel implanted with Ti and C. D.M.Follstaedt, F.G.Yost, L.E.Pope, S.T.Picraux, J.A.Knapp (Sandia Nat Labs., Albuquerque, NM, USA).
Appl. Phys. Lett. (USA), vol.43, no.4, p.358-60 (15 Aug. 1983).
The wear tracks resulting from unlubricated pin-on-disc tests of 304 stainless steel which was ion implanted with Ti and C have been examined with transmission electron microscopy, scanning electron microscopy, and energy dispersive X-ray spectroscopy. At light pin loads, where the maximum wear depths were reduced by the implantation from ~1.5 to ~0.15 μm, nearly continuous amorphous layers containing Ti were found to exist across the wear tracks. However, the amorphous phase was not observed in deeper wear tracks (≳1 μm) produced by higher loads. This correlation of the presence of the amorphous layer with reduced wear demonstrates that this layer is reponsible for the reduction in wear produced by implantation of Ti and C. (13 refs.)

109518 Plastic deformation and wear process at a surface during unlubricated sliding. T.Yamamoto, D.H.Buckley (Lewis Res. Center, NASA, Cleveland, OH, USA).
ASLE Trans. (USA), vol.26, no.3, p.277-87 (July 1983).
The plastic deformation and wear of a 304 stainless steel surface sliding against an aluminium oxide rider with a spherical surface (the radius of curvature: 1.3 cm) were observed by using scanning electron and optical microscopes. Experiments were conducted in a vacuum of 10^{-6} Pa and in an environment of 5×10^{-4} Pa of chlorine gas at 25°C. The load was 500 grams and the sliding velocity was 0.5 centimeter per second. The deformed surface layer which accumulates and develops successively is left behind the rider, and step-shaped protruberances are developed even after single-pass sliding under both environmental conditions. A fully developed surface layer is gradually torn off leaving a characteristic pattern. The mechanism for tearing away of the surface layer from the contact area and sliding track contour is explained assuming the simplified process of material removal based on the adhesion theory for the wear of materials. (15 refs.)

109519 Tribological characteristics of nitrogen (N^+) implanted iron. W.R.Jones,Jr., J.Ferrante (Lewis Res. Center, NASA, Cleveland, OH, USA).
ASLE Trans. (USA), vol.26, no.3, p.351-9 (July 1983).
The effect of implantation of nitrogen ions (1.5 MeV) on the friction and wear characteristics of pure iron sliding against M-50 steel (unimplanted) was studied in a pin-on-disk sliding friction apparatus. Test conditions included room temperature (~25°C), a dry air atmosphere, a load of $^1/_2$ kg (4.9 N), sliding velocities of 0.043 to 0.078 m/s (~15 to 25 rpm), a pure hydrocarbon lubricant (n-hexadecane), or a USP mineral oil and nitrogen ion implantation doses of 5×10^{15} and 5×10^{17} ions/cm^2. No differences in wear rates were observed in the low-dose (5×10^{15} ions/m^2) experiments. In the high-dose experiments (5×10^{17} ions/cm^2), small reductions in initial (~40 percent) and steady-state (~20 percent) wear rates were observed for nitrogen-implanted iron riders as compared with unimplanted controls. No differences in average friction coefficients were noted for either dose. Auger electron spectroscopy combined with argon ion bombardment revealed a subsurface Gaussian nitrogen distribution with a maximum concentration of 6 atomic percent at a depth of 8×10^{-7} m (0.8 μm). Similar analysis within the wear scar (~2.0×10^{-5} m subsurface) of an implanted rider after 20 μm of wear yielded only background nitrogen concentration. No inward migration of nitrogen ions was observed. (25 refs.)

109520 Fabrication and wear test of a continuous fiber/particulate composite total surface hip replacement. J.C.Roberts, F.F.Ling, W.R.Jones,Jr. (Lewis Res. Center, NASA, Cleveland, OH, USA).
ASLE Trans. (USA), vol.26, no.3, p.367-75 (July 1983).
Continuous fiber woven E-glass/epoxy composite femoral shells having the same elastic properties as bone have been fabricated. These shells were coated with filled epoxy wear-resistant coatings consisting of 1 to 64 micron particles of: Al_2O_3, Al_2O_3+Cu, and 18-8 stainless steel+Al_2O_3 in an epoxy matrix. The resulting femoral shells were wear tested dry against ultrahigh-molecular-weight polyethylene (UHMWPE) acetabular cups for up to 250000 cycles on a total hip simulator. The best femoral shell tested was the one containing particles of 18-8 stainless steel+Al_2O_3 in an epoxy base. Articulation of this shell dry against UHMWPE for 250000 cycles resulted in a friction force that was about 10 percent lower than that of the current total hip prosthesis; that is, a vitallium ball articulating dry with an UHMWPE cup. Addition of graphite fibers to the UHMWPE acetabular cup and articulation with the 18-8 stainless steel+Al_2O_3 epoxy shell increased the friction force but reduced the surface damage to the UHMWPE. When femoral shells containing Al_2O_3+Cu particles in an epoxy matrix were run dry against UHMWPE for 42000 cycles the friction force was continually increasing and there was evidence of more surface damage to the UHMWPE cup than when the shell contained particles of 18-8 stainless steel+Al_2O_3. (28 refs.)

109521 Tribochemical processes and wear resistance of polymeric materials. V.V.Korshak, I.A.Gribova, A.P.Krasnov, V.N.Aderikha (Inst. of Organo-Element Compounds, Acad. of Sci., Moscow, USSR).
ASLE Trans. (USA), vol.26, no.3, p.401-4 (July 1983).
Tribochemical transformations of polyphenylquinoxaline (PPQ) and a composite material on its basis containing graphite are investigated. A mass-spectrometric analysis shows that in the polymer surface layers the destructive-structurizing processes occur on friction that changes the structure and properties of the surface layer. It is shown that, in the presence of a graphite

filler, the tribochemical transformation character also changes. Based on the investigation data, a general scheme of tribochemical changes of PPQ is proposed and their relation to wear is suggested. (8 refs.)

109522 The role of copper-base alloys in tribological experiments and applications. A.D.Sarkar (Dept. of Mech. Engng., Univ. of Petroleum & Minerals, Dhahran, Saudi Arabia).
Arabian J. Sci. & Eng. (GB), vol.8, no.2, p.113-21 (April 1983).
The effect of geometry on the wear rates of brass is examined by carrying out experiments using laboratory machines. It is shown that an empirical relationship between the volume, V, lost due to wear and the contact stress σ can be obtained, but V is not directly proportional to σ. Some results of wear studies using binary Cu-Zn and Cu-Sn alloys are reported. It is noted from a review of the literature that the wear resistance of copper-base alloys can be improved by increasing the tin and lead content. It is recommended that further laboratory studies on the wear of copper-base alloys will be of value. (13 refs.)

109523 Abrasive wear in uni-directional friction and reciprocating friction. N.Yahata (Dept. of Mech. Engng., Tokyo Univ. of Agriculture & Technol., Koganei, Japan).
J. Jpn. Inst. Met. (Japan), vol.47, no.8, p.692-8 (Aug. 1983). In Japanese.
A comparison of abrasive wear between uni-directional friction and reciprocating friction was made on annealed plain carbon steels sliding against fresh Al_2O_3 abrasive cloths and repeatedly used ones. Wear tests of the two sliding modes were carried out with a testing machine, remodeled from a lathe under similar conditions in air. The experiments indicated that in case of fresh abrasive cloths, a heavier wear always resulted from uni-directional friction, and the wear differences between the two sliding modes increased with increasing normal forces and abrasive grain sizes; in case of repeatedly used ones, a heavier wear resulted from reciprocating friction in steady conditions. The wear differences between the two sliding modes can be explained in terms of the differences in the degree of work-hardening of the rubbed surfaces and the amount of the abrasive grains being blunted, fractured, eroded out of the resin base, clogged and capped with metal chips etc. (13 refs.)

109524 Structure and wear properties of Al-Sn alloy produced by electroslag remelting. Hoon Yung Young (Coll. of Engng., Yon Sei Univ., Seoul, Korea), Jin Il Choi, Ki Young Kim.
J. Korean Inst. Met., vol.21, no.5, p.469-81 (May 1983). In Korean.
Experiments were carried out to investigate the effect of various casting processes such as sand casting, chill casting and ESR, and also of nickel addition on the structure and sliding wear properties of Al-Sn alloy containing up to 20% tin. The results obtained are as follows: (1) Addition of nickel to the Al-Sn alloy produced by sand casting and ESR was effective to refine tin particles, while there was no structural change in chill cast alloy. (2) The wear resistance of the alloy produced by ESR was superior to that by sand casting and chill casting. The wear resistance varied with sliding conditions, but better wear resistance was achieved with a continuously networked tin structure. (3) In the sliding wear of Al-Sn alloy, abrasive and adhesive wear, occured, while oxidizing wear was not recognized. (4) In the wear test of Al-Sn alloy, the average size of wear debris and the wear amount increased with increasing sliding speed, and both of them were also found to be in proportion. (24 refs.)

109525 Metastable austenitic Cr-Mn steels. M.A.Filippov (S.M. Kirov Ural Polytech. Inst., Sverdlovsk, USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.751-5 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.2-7 (Nov. 1982).
It is concluded that the contact strength of machine parts operating under various conditions of contact dynamic loading (cavitation-erosion, gas erosion, friction, and impact-abrasive wear) can be improved substantially by using Cr-Mn MAS steels. The resistance of Cr-Mn MAS depends on the conditions of CDL, the rate of the martensitic transformation, and the properties of the phases formed. For applications involving cavitation steels containing 0.1-0.3% (C+N) of the 10Kh14AG12-30Kh10G10 type are recommended, in which the $\gamma \rightarrow \epsilon$ and $\gamma \rightarrow \alpha$ martensitic transformations occur at a high rate; steels with a high carbon content (0.6-0.8%) in which the $\gamma \rightarrow \alpha$ transformation is the primary transformation under load (steels of the 60Kh5G10L-70Kh4G8L type) are promising for impact-abrasive wear conditions. (22 refs.)

109526 Modification of Kh12M steel. A.E.Pavaras, A.N.Popandopulo, P.I.Ambrosa, A.F.Vishkarev, V.V.Savinov (Kaunas Polytech. Inst., Kaunas, USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.793-7 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.36-8 (Nov. 1982).
It was found advisable to modify steels of the Kh12M type with aluminum, yttrium, and boron, since this helps to achieve more uniform distribution of eutectic carbides, to decrease segregation of alloying elements, and to decrease sensitivity of the steel to overheating. Carbide inclusions in forged and annealed modified steel Kh12M are small in size and of characteristic shape. Modification of steel Kh12M promotes transformation of austenite during tempering, promotes precipitation hardening, improves mechanical properties, and increases by 1.5-2 times the wear resistance of tools. (2 refs.)

109527 Lubrication of high temperature ceramic materials. B.Longson (Nat. Centre of Tribology, Risley, England).
Tribology Int. (GB), vol.16, no.4, p.221-5 (Aug. 1983).
A composite of $CaF_2/BaF_2/Ni$ was shown to be an effective lubricant for a silicon carbide ceramic and a titanium carbide/nickel cermet when tested as like pairs in crossed cylinders geometry at room temperature and at 600°C. (18 refs.)

109528 The effect of particle shape and size on erosion of aluminum alloy 1100 at 90° impact angles. R.Brown (Dept. of Chem. Engng., Univ. of Rhode Island, Kingston, RI, USA), S.Kosco, E.J.Jun.
Wear (Switzerland), vol.88, no.2, p.181-93 (1 July 1983).
Aluminum alloy 1100 was eroded by 70 μm and 210 μm silica spheres and by 210 μm angular quartz particles at a velocity of 122 m s^{-1} and at an impact angle of 90°. Extensive scanning electron microscopy examination of eroded surfaces, erosion debris and metallographic sections, together with transmission electron microscopy examination of debris and eroded surfaces, was conducted. Hills and valleys were formed during the incubation period of erosion for all types of erodent. During steady state erosion small nonfragmenting erodent removed material by a flaking mechanism in valleys. For larger fragmenting erodent four additional mechanisms aiding erosion were identified. Furthermore, a threshold particle size for hill and valley formation is proposed. The implication of this on the magnitude of the erosion rate is discussed. (27 refs.)

109529 Effect of aqueous cations on friction between rubber and glass. L.Sokoloff, S.L.Lee (Dept. of Pathology & Mech. Engng., State Univ. of New York, Stony Brook, NY, USA).
Wear (Switzerland), vol.88, no.2, p.207-19 (1 July 1983).
The coefficient of friction μ between plate glass and natural rubber subjected to boundary lubrication by various isotonic salt solutions was measured. All the monovalent chloride solutions tested (Na^+, K^+, Li^+, $NH_4{}^+$, $(CH_3)_3NH^+$ and $(CH_3)_4N^+$) reduced the value of μ below that obtained using distilled water as the lubricant. The divalent cations test (Ca^{2+}, Ba^{2+} and Mg^{2+}) and La^{3+} increased μ. The effects of Fe^{3+} and Al^{3+} were anomalous. Little increase in friction was observed in the presence of these cations, but large increases in μ were obtained after they had been rinsed away with NaCl. Immersion in water increased the extensibility of the rubber relative to that obtained in air. The addition of monovalent cations had no measurable effect on the elastic properties on the elastic properties of the rubber. The friction increased progressively when the pH of the NaCl solutions was reduced below 4 by adding HCl solution. Desorption experiments showed that the rubber adsorbed $^{45}Ca^{2+}$. The effect was competitively inhibited by the addition of 0.1 and 1 M non-isotopic $CaCl_2$. (29 refs.)

109530 Study of rolling friction—behaviour of the small displacement of starting rolling friction. T.Koizumi (Dept. of Mech. Engng. for Production, Tokyo Inst. of Technol., Tokyo, Japan), H.Shibazaki, T.Nishio, N.Nishiwaki.
Wear (Switzerland), vol.88, no.3, p.285-96 (15 July 1983).
In this study the detailed behaviour of the starting rolling displacement at the contact of a flat steel surface with a steel roller is investigated. In addition, the behaviour of the hysteresis loop formed in the region of the starting rolling distance is experimentally examined by varying the hardness of the rolling contact surface and the radius of the roller. From the results it is found that the contact width is closely related to the rolling friction force, that the area of the hysteresis loop increases proportionally to the second power of the starting rolling distance and that the maximum width of the hysteresis loop shows almost the same value as the half-contact width calculated by Hertz' theory. (11 refs.)

109531 A critical study of the erosion of an aluminium alloy by solid spherical particles at normal impingement. A.K.Cousens, I.M.Hutchings (Dept. of Metall. & Materials Sci., Univ. of Cambridge, Cambridge, England).
Wear (Switzerland), vol.88, no.3, p.335-48 (15 July 1983).
Detailed observations of the mechanism of material removal in aluminium alloys eroded at normal incidence by spherical particles are reported. Eroded specimens were examined by scanning electron microscopy and were sectioned for metallographic examination. Important features observed included surface ripples of uniform wavelength and the formation of platelets on the surface. Beneath each surface examined was a layer, clearly delineated from the bulk material, with approximately four times the hardness of the bulk. This layer had a laminar structure and contained numerous embedded fragments of erodent particles. The layer was of relatively uniform thickness and was perforated in places by bulk material penetrating to the surface. In the early stages of erosion, before a linear erosion rate is established, the subsurface microstructure is developed. Then, by a process akin to backward extrusion, bulk material is forced to the surface through fissures in the hard layer. (18 refs.)

109532 Deformation by scratches and frictional properties of MgO crystals. Y.Enomoto (Mech. Engng. Lab., Ibaraki, Japan).
Wear (Switzerland), vol.89, no.1, p.19-28 (1 Aug. 1983).
The subsurface structure of MgO crystals frictionally damaged on their (001) faces by scratching with a diamond stylus in the $\langle 100 \rangle$ direction was investigated using a scanning electron microscope in both the cathodoluminescence and the secondary electron modes. The friction is independent of the load below a critical value, and above this value it depends on the load W according to $\mu \propto W^n$ where μ is the coefficient of friction. The subsurface beneath the sliding contact consists of four characteristic material zones: zone I is severely deformed with a high defect density which causes quenching of the luminescence; zone II is a plastically deformed intermediate zone showing enhanced luminescence; zone III is a slipped zone which on etching shows a dislocation pit pattern; zone IV consists of non-deformed crystalline material. The normalized depth d/a, where d is the depth of each deformed zone and a is the track half-width, is independent of the load. The frictional behaviour was examined by using empirical relations for the damage to estimate the plastic work done during the scratching process. (19 refs.)

109533 Antiwear property of lubricant additives for high silicon aluminium alloy under boundary lubricating conditions. M.Kawamura, K.Fujita (Toyota Central Res. & Dev. Labs., Aichi-ken, Japan).
Wear (Switzerland), vol.89, no.1, p.99-105 (1 Aug. 1983).
The antiwear effects of phosphates, phosphites and zinc dialkyldithiophosphates (ZnDTPs) were examined by the use of a cross-pin-type lubricant tester for a high silicon aluminium alloy boundary lubrication conditions. The reactivity of the additives with metals was studied by differential thermal analysis. Phosphates and phosphites containing straight chain alkyl groups showed smaller wear scar diameters than those containing branched or aryl groups. The reactivity of the additives did not correlate with the antiwear property. The results suggest that the oiliness effect is a dominant factor. ZnDTPs showed good antiwear properties, which may be attributed to the adsorption of the additives or the formation of a friction polymer. (7 refs.)

109534 Observation of wear damage of a hot isostatically pressed alumina cutting tool by cathodoluminescence. Y.Enomoto (Mech. Engng. Lab., Ibaraki, Japan), K.Fujise.
Wear (Switzerland), vol.89, no.1, p.107-11 (1 Aug. 1983).
Recent work has shown that the observation of cathodoluminescence (CL) from the wear damage of brittle materials provides one with fruitful information about plastically deformed zones and subsurface microcracks. This technique is applied to study the wear behaviour of a hot isostatically pressed (HIP) α-alumina cutting tool. Wear damage of the tool tip was observed using a JEOL JL-35C scanning electron microscope in both the CL mode (emission at all wavelengths) and the secondary electron (SE) mode at an accelerating voltage of 25 kV. It can be observed that, in the CL micrograph, three large dark zones exist at the flank face, i.e. about the outside zones of primary grooves and secondary grooves and about the central zone. These dark zones primarily correspond to the deposited area of steel material transferred from the workpiece. (6 refs.)

109535 Magnetic properties of alloy 40KhNYu-VI. V.A.Petrov, L.I.Vershinina, R.D.Strokatov, V.F.Sukhovarov (Inst. of Atmospheric Optics, Acad. of Sci., Tomsk, USSR).
Fiz. Met. & Metalloved. (USSR), vol.56, no.1, p.72-6 (July 1983). In Russian. English translation in: *Phys. Met. & Metallogr. (GB)*
Magnetic properties and structure of a dispersion-hardening industrial alloy 40KhNYu-VI were investigated. X-ray structure analysis and electron microscopy showed that nickel particles precipitated within primary particles of the α-phase. The Kondorskii theory was used to discuss the magnetic properties of alloys and to determine the volume fraction of ferromagnetic particles. The range of existence of the ferromagnetic state was established experimentally. (8 refs.) *A.T.*

Z. Metallkd. (Germany), vol.74, no.8, p.500-3 (Aug. 1983). In German.
During slow cooling of Cu-Ni-Fe alloys with a similar composition as the technically important alloys CuNi10Fe and CuNi30Fe nickel rich Fe-Ni particles are formed. For these particles a nickel content of 60 to 70% could be determined from the ferromagnetic behaviour of $(Cu_{0.9}Ni_{0.1})_{0.98}Fe_{0.02}$ and the superparamagnetic behaviour of $(Cu_{0.7}Ni_{0.3})_{0.98}Fe_{0.02}$. The decrease of iron in the matrix may cause a deterioration in corrosion resistance. (18 refs.)

109537 Polishing hard materials. A.P.Smith (Div. of Manufacturing Technol., CSIRO, Melbourne, Australia).
Am. Ceram. Soc. Bull. (USA), vol.62, no.8, p.886-8 (Aug. 1983).
The development of a polishing technique for polishing hard materials (DPH>800) is described. A grooved and etched tin lap was found to produce excellent polishes on a range of hard materials such as carbides, ceramics, refractories, and minerals. The results show improved flatness together with significantly increased polishing rates when compared with existing techniques. Details of lap construction are described, including an etching technique which enables rapid and reliable refurbishing of the lap surface. (9 refs.)

109538 XPS and XAES studies of transient enhancement of Cu^I at CuO surfaces during vacuum outgassing. J.P.Tobin, W.Hirschwald, J.Cunningham (Inst. of Phys. Chem., Free Univ. Berlin, Berlin, Germany).
Appl. Surf. Sci. (Netherlands), vol.16, no.3-4, p.441-52 (July-Aug. 1983).
Vacuum outgassing of CuO powder at 473K gives rise to Cu^I formation at the surface. This process is reversed by heating to 673K in vacuo. From the changes in relative surface concentration of the components as measured by XPS and AES and from mass spectrometric observations it is concluded that surface reduction by impurity carbon is responsible for the formation of Cu^I from Cu^{II} and that charge transfer between bulk and surface layer causes the retransition. (12 refs.)

109539 The oxidation behaviour of silicon-infiltrated silicon carbide. U.Ernstberger, H.Cohrt, F.Porz, F.Thummler (Inst. fur Werkstoffkunde II, Univ. Karlsruhe, Karlsruhe, Germany).
CFI-Ceram. Forum Int. Ber. Dtsch. Keram. Ges. (Germany), vol.60, no.5-6, p.167-73 (30 July 1983). In German, English.
The oxidation behaviour of silicon-infiltrated silicon carbide was investigated for the 1150...1350°C temperature range. A passivating protective coating was found to form in the presence of a high oxygen partial pressure (air under atmospheric pressure). Oxidation progresses according to a parabolic function in which the velocity constants are located between those of silicon and those of pressureless-sintered silicon carbide. The protective coating does not develop smoothly across the composite SiSiC, as would be the case for polycrystalline or monocrystalline silicon or silicon carbide, but instead remains extensively rugged on top of the silicon phase. This is attributable to the presence of impurities in the material. At considerably low oxygen partial pressures ($p_{O2}=4\times10^{-6}$ bar), there occurs a temperature-and gas-flow-velocity-dependent reduction in mass (active oxidation), which gradually vanishes due to the emergence of an SiO(g) equilibrium partial pressure in the pores formed through the heavy attack of the silicon phase. (19 refs.)

109540 Knurl roll design for stable rotogravure coating. W.W.Pulkrabek (Dept. of Mech. Engng., Univ. of Wisconsin-Platteville, Platteville, WI, USA), J.D.Munter.
Chem. Eng. Sci. (GB), vol.38, no.8, p.1309-14 (1983).
When a thin film of fluid is coated on a web by any type roll or spreader coater such that the fluid splits while in a divergent channel the resulting fluid surface is not smooth but is made up of ridges, running in the direction of coating. At production speeds (50 m/min and higher) there is a natural frequency of this fluid ribbing effect which is independent of the type of coater and fluid rheology, and depends only on the depth of the wet coat of transferred liquid. A study has been made to determine how this natural ribbing frequency is related to coating stability on a rotogravure coater with a ruling mill knurled coating roll. It has been observed that many knurl rolls deposit a metastable fluid pattern on the web when the resulting fluid surface matches the knurl pattern of the roll. Under some coating conditions this resulting surface becomes unstable and the fluid is transferred to a condition of fewer ridges per cm, resulting in a nonuniform coated surface. (11 refs.)

109541 Titanium oxycarbide on TiC (100) surface. C.Oshima, S.Otani, M.Aono (Nat. Inst. for Res. in Inorganic Materials, Ibaraki, Japan), S.Zaima, Y.Shibata.
Jpn. J. Appl. Phys. Part 1 (Japan), vol.22, no.6, p.930-3 (June 1983).
Experimental data on chemical composition, atomic structure and electronic structure strongly suggests that titanium oxycarbide, TiO_xC_{1-x}, a mixed phase of TiO and TiC, is formed on the surface when a TiC (100) surface is exposed to oxygen and is then heated at ~1000°C in an ultra-high vacuum. (14 refs.)

109542 A Monte Carlo study of Si(111) surface oxidation. S.E.Goodnick, W.Porod, R.O.Grondin, S.M.Goodnick, C.W.Wilmsen, D.K.Ferry (Dept. of Electrical Engng., Colorado State Univ., Fort Collins, CO, USA).
J. Vac. Sci. & Technol. B (USA), vol.1, no.3, p.767-72 (July-Sept. 1983). (10th Annual Conference on the Physics and Chemistry of Semiconductor Interfaces, Santa Fe, NM, USA, 25-27 Jan. 1983).
A theoretical study of the initial oxidation stages of Si(111) surfaces is undertaken. A Monte Carlo simulation is used to study the individual surface processes that have been suggested in the literature. The relative importance of these mechanisms for the chemical composition of the oxide layer as well as for the initial stages of the formation of SiO_x is investigated. (21 refs.)

109543 Elevated temperature low energy ion cleaning of GaAs. P.Oelhafen, J.L.Freeouf, G.D.Pettit, J.M.Woodall (IBM Res., Yorktown Heights, NY, USA).
J. Vac. Sci. & Technol. B (USA), vol.1, no.3, p.787-90 (July-Sept. 1983). (10th Annual Conference on the Physics and Chemistry of Semiconductor Interfaces, Santa Fe, NM, USA, 25-27 Jan. 1983).
The authors have studied various cleaning procedures for obtaining atomically clean, well-ordered surfaces of GaAs(100) and (110). They have evaluated the resulting surfaces by angle resolved ultraviolet photoelectron spectroscopy (ARUPS), X-ray photoelectron spectroscopy (XPS), and low energy electron diffraction (LEED). They report results for thermally cleaned, ion bombarded and annealed, and ion bombardment at elevated temperature cleaning procedures. The most reproducible results, giving the best, lowest background LEED patterns and the sharpest ARUPS results, were obtained from the elevated temperature ion bombardment cleaned samples. The thermally cleaned samples, while showing low impurity concentrations to XPS studies, had a relatively high background LEED pattern. The ARUPS results were not indicative of a high degree of surface order; the normal emission spectra more resemble angle integrated UPS results. The room temperature ion bombarded samples, followed by anneals of 30 min at temperatures up to 520°C, yielded a high quality 1×1 pattern on a GaAs(100) surface, but no higher order reconstruction could be obtained. The ion bombardment typically used in this work was 200 eV Ar ions. Substrate temperature during bombardment were varied from 300 to 800K. Post anneals were also examined. Temperatures of 300°C were quite adequate to obtain a high quality 1×1 LEED pattern on both (100) and (110) surfaces. Post anneals at 520°C yielded a low background (8×2)Ga surface. (8 refs.)

109544 Cleaning chemistry of GaAs(100) and InSb(100) substrates for molecular beam epitaxy. R.P.Vasquez, B.F.Lewis, F.J.Grunthaner (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
J. Vac. Sci. & Technol. B (USA), vol.1, no.3, p.791-4 (July-Sept. 1983). (10th Annual Conference on the Physics and Chemistry of Semiconductor Interfaces, Santa Fe, NM, USA, 25-27 Jan. 1983).
The widely accepted sample-cleaning procedure for MBE substrates, involving the thermal desorption of native oxide-passivation layers in UHV, is examined using high resolution X-ray photoelectron spectroscopy. Oxide composition, carbon contamination, and substrate surface stoichiometry are followed for a variety of temperatures, for GaAs, $In_xGa_{1-x}As$, and InSb substrates. The oxide desorption mechanism observed involves thermal reduction of As^{+5} to As^{+3} resulting in the further oxidation of the GaAs substrate surface and the additional formation of Ga_2O_3 and As^0. At higher temperatures, first the As_2O_3 desorbs followed by the loss of Ga_2O_3. Carbon-contamination levels were minimized (<0.5% of a monolayer) by the etch removal of the chemical passivating layer by a HCl/EtOH strip immediately prior to vacuum introduction of the sample. The etch is done in inert-atmosphere conditions and gives total removal of both arsenic and gallium oxides, yet leaves the substrate stoichiometry unmodified. The method was quite effective for the $In_xGa_{1-x}As$ (x=0-1) system; however, halide-passivation films gave better results on InSb. (19 refs.)

109545 Photoelectrochemical passivation of GaAs surfaces. J.M.Woodall, P.Oelhafen, T.N.Jackson, J.L.Freeouf, G.D.Pettit (IBM Res. Yorktown Heights, NY, USA).
J. Vac. Sci. & Technol. B (USA), vol.1, no.3, p.795-8 (July-Sept. 1983). (10th Annual Conference on the Physics and Chemistry of Semiconductor Interfaces, Santa Fe, NM, USA, 25-27 Jan. 1983).
A wet chemical technique is described for passivating air-exposed GaAs surfaces. The passivating layer is elemental arsenic which forms as a result of illuminating an n-type GaAs wafer immersed in a mixture of HCl acid and deionized 18 MΩ water with light from a mercury vapor lamp at intensities of 0.01-0.05 W-cm^{-2}. Studies using XPS, LEED, and UPS show that the passivated surfaces have the following properties: (1) there is little or no Ga or Ga and As oxide species in the As film or at the film/GaAs interface; (2) a strong GaAs LEED pattern is observed after a 290°C anneal following low energy ion beam bombardment. This suggests that the As/GaAs interface formed by photoetching is free of contaminates and the the GaAs surface is wellordered prior to ion bombardment at heat treatment. Thus, clean, well ordered surface of GaAs which have been previously air exposed can now be

obtained at lower temperatures than previously. This creates new possibilities for surface studies, epitaxy, and metallization. (15 refs.)

109546 Some investigations on anodic oxide films on gallium arsenide. C.Ghosh, W.Polhamus (ITT Electro-Optical Products Div., Roanoke, VA, USA).
J. Vac. Sci. & Technol. B (USA), vol.1, no.3, p.837-9 (July-Sept. 1983).
The anodic oxides on metal-organically grown GaAs have been investigated by Auger and secondary ion mass spectroscopy (SIMS). The surface of the oxide was found to contain carbon contamination amounting to ~7 at.%. The carbon contamination was no longer detectable after Auger sputter profiling for 0.6 min (at a rate of 40 Å/min for Ta_2O_5). Carbon contamination to similar depth on the surface was also observed on freshly etched GaAs. Auger analysis results show a Ga to As atomic ratio of 6:1 for the oxide. As the oxide/GaAs interface is approached, the As concentration increases sharply. The SIMS spectra of the surface and the bulk of the oxide does not show the presence of Ga_2O_3 and As_2O_3, believed to be the main constituents of anodic oxides, but peaks corresponding to GaO and AsO and elemental Ga and As are observed. This is probably due to decomposition of Ga_2O_3 and As_2O_3 because of argon ion bombardment. (15 refs.)

109547 Radio frequency reactive sputter etching—control of etch rates. C.M.Horwitz (Res. Lab. of Electronics, MIT, Cambridge, MA, USA).
J. Vac. Sci. & Technol. B (USA), vol.1, no.3, p.840-3 (July-Sept. 1983).
Etch rate variability in a reactive sputter-etching process can come from many factors, and here the etching of SiO_2 in CHF_3 is used in a study of the effects of various parameters on the etch rate, although other materials are also considered. It is found that this SiO_2/CHF_3 combination is remarkably insensitive to chamber pump-out time and the initial chamber condition, at least at high applied RF voltages (1.5 kV peak to peak). However, the gas pressure, flow rate, applied RF voltage, and the target electrode configuration do have a strong effect on rates. This latter result is shown to agree with presently available data on the capacitance of sputtering glow discharges. An etch rate reproducibility of ±2% over a period of four months has been demonstrated. (15 refs.)

109548 Numerical simulation of the long-term performance and corrosion of photoelectrochemical cells. H.Flaisher, R.Tenne (Dept. of Plastics Res., Weizmann Inst. of Sci., Rehovot, Israel).
J. Phys. Chem. (USA), vol.87, no.16, p.3061-8 (4 Aug. 1983).
A computer progam which simulates the long-term operation of a photoelectrochemical cell (PEC) has been devised by using the basic chemical reactions which are supposed to occur at the surface of the semiconductor electrode. The model takes into account the buildup of a top passivating layer. The rate constants for these reactions were derived implicitly by varying them until the results of the model were comparable to those obtained experimentally for the CdSe/polysulfide photoelectrochemical cell. Once these constants were found, the program was used to simulate experimental curves of efficiency as a function of the cell parameters and time. The ratio of peak photocurrent and steady-state photocurrent was evaluated as well. Effects of solution concentration, incident light intensity, and surface roughness (e.g. by photoetching) were all observed by using the model. These results are in qualitative agreement with many independent experimental observations. For a given electrode, when the rate of hole transfer into the electrolyte is increased (i.e. increased quantum yield), the rate of the electrode deactivation decreases in accordance with experimental observations. (20 refs.)

109549 Ion sputtering and its application to biomaterials [reviews]. W.Kowalski (Tech. Univ. of Wroclaw, Wroclaw, Poland).
J. Mater. Sci. (GB), vol.18, no.9, p.2531-43 (Sept. 1983).
The mechanisms of surface morphology and chemistry changes induced by ion sputtering of solids are reviewed and the influence of ion processing on surface morphology and chemical composition of biological implant materials is discussed. The influence of the ion bombardment induced morphological and chemical changes of biomaterials on mechanical properties and tissue response is also presented. (59 refs.)

109550 A proposed diamond polishing process. C.Jeynes (H.H. Wills Phys. Lab., Univ. of Bristol, Bristol, England).
Philos. Mag. A (GB), vol.48, no.2, p.169-97 (Aug. 1983).
A two-stage, predominantly brittle wear-chip mechanism is developed which may describe fine polishing with diamond grit having sizes in the range 2-10 μm. (Coarser grits do not give a fine polished surface). In the first stage, the size of the wear chips is determined by cracking in the elastic stress field behind the polishing grains. This field is pseudo-Hertzian: it is supposed not to be qualitatively changed by the presence of some plastic deformation. In the second stage, wear chips may be released by various other mechanisms not discussed in detail; their release will be encouraged by plastic deformation. The model predicts that Auerbach's constant will be increased by a factor of 2 for micrometre-sized indenters. The discussion draws attention to the effects of different ranges of grain size in the diamond polishing process; the mechanism described cannot be valid, either for submicrometre-sized grits, where plastic deformation is thought to predominate, or for heavily loaded stones, where part of the load is borne by the cast-iron polishing wheel. (71 refs.)

109551 Observation of oxidation of germanium in the column of an electron microscope. N.V.Rozhanskii, V.A.Arslambekov (Inst. of Phys. Chem., Acad. of Sci., USSR).
Sov. Phys.-Crystallogr. (USA), vol.28, no.1, p.78-9 (Jan.-Feb. 1983). Translation of: *Kristallografiya (USSR)*, vol.28, no.1, p.143-5 (Jan.-Feb. 1983). [received: Sept. 1983]
The authors have studied the oxidation of the (111) surfaces of small Ge crystals in the column of an electron microscope at $T=550°C$ under a pressure of oxygen of about 1 torr. The crystals were thinned owing to the formation of the voltatile germanium monoxide GeO. In parallel with the formation and evaporation of GeO, crystals of the hexagonal modification of GeO_2 grew on the surface in the epitaxial orientations $(0001)GeO_2 \| (111)Ge$, $\langle 10\bar{1}0 \rangle GeO_2 \| (112)Ge$. (7 refs.)

109552 Production and properties of low electrical resistance molybdenum silicide layers. G.Beddies, K.Hofmann, W.Bretschneider, H.-D.Zscheile, P.Bogdanowa, H.Helms, K.-H.Wickleder (Sektion Phys., Tech. Hochschule Karl-Marx-Stadt, Karl-Marx-Stadt, Germany).
Wiss. Z. Tech. Hochsch. Karl-Marx-Stadt (Germany), vol.25, no.2, p.188-96 (1983). In German.
Until recently poly-silicides were used for the production of protective layers on some materials, but their relatively high resistance, i.e. about 3 ohm, prompted a search for a more suitable material. This is a crystalline phase of $MoSi_2$. The silicide is precipitated on the surface of the material to be coated in two forms as a double layer or as a mixed layer. The technique of coating involves spraying in a high vacuum environment. The layers are then tested for electrical resistance, mechanical durabiity and microscopic structure. The equipment used in the process of coating is illustrated and the technique of spraying is described. Tests have shown that increasing the silica content in the coating compound results in a small increase in the specific resistance. Photometer curves show a bending diagram of a Mo/Si layer at various temperatures. (5 refs.) *G.R.S.*

109553 Friction oxidation characteristics. F.Arezzo (Kearfott, Little Falls, NJ, USA).
ASLE Trans. (USA), vol.26, no.3, p.288-92 (July 1983).
A mechanism is proposed to account for the friction oxidation that occurs in steel bearings subjected to small amplitude oscillations. It was developed from analysis of data obtained from an apparatus used to rate the lubricity of greases. The heat generated in poorly lubricated bearings increases the rate at which iron oxide forms. The oxide builds up until it can no longer sustain the resulting load; then the oxide layer collapses, contributing abrasive particles that cause additional wear. (8 refs.)

109554 Experience with titanium-tubed condensers and coolers in Swedish nuclear power stations. I.Multer (Swedish State Power Board, Vallingby, Sweden).
VGB Kraftwerkstech. (German Ed.) (Germany), vol.63, no.6, p.487-90 (June 1983). In German.
The subject of the paper is the experience of Swedish nuclear power stations with special brass-tubed condensers and the application of an $FeSO_4$ protective layer which is an extremely problematical operation caused by Swedish relationships with very low cooling water temperatures. The paper demonstrates to what extent effective life is attained using these special brass-tubed condensers and the requirements which have led to almost all condensers being retro-fitted with titanium in the meantime. Economic comparison shows that over the foreseen life titanium condensers are about US $14 million less expensive than special brass-tubed condensers. (no refs.)

109555 Aluminium distribution in the coating developed by hot dip galvanizing of silicon semi-killed steel samples. M.Seraoui, C.Reille, N.Tabet, B.Schmitt (Univ. de Constantine, Constantine, Algeria).
C.R. Seances Acad. Sci. Ser. II (France), vol.296, no.20, p.1587-9 (6 June 1983). In French.
Aluminium localization with regard to Fe-Zn compounds of the galvanizing coating developed on a silicon semi-killed steel, is in relationship with immersion time. Aluminium, at first concentrated in the steel/η phase interface, is distributed after, in the δ_1/ζ and ζ/η interfaces. The ζ phase formation takes place before the decomposition of the iron-aluminium metastable phases which gives rise to the δ_1 compound. (7 refs.)

109556 Oxidation of $2^1/_4$ Cr-1 Mo steel in oxygen, oxygen-water vapour mixture at high temperature. A.S.Khanna (Materials Dev. Lab., Reactor Res. Centre, Kalpakkam, India), K.P.Singh.

Trans. Indian Inst. Met., vol.35, no.5, p.494-6 (Oct. 1982). [received: Aug. 1983]

Oxidation experiments were carried out on 1 mm thick strips of Cr-Mo steel. From the results it is clear that as the temperature increases, the behaviour becomes less parabolic. Oxidation in oxygen-water vapour mixture is higher than in pure oxygen at all temperatures. (9 refs.)

109557 Oxidation of thin Cd, Cu and Te films under continuous laser irradiation. M.Wautelet (Faculte des Sci., Univ. de l'Etat, Mons, Belgium).

Mater. Lett. (Netherlands), vol.2, no.1, p.20-2 (July 1983).

Thin films of Cd, Cu and Te are irradiated in air by means of a continuous, unfocused laser beam. The diameter of the oxidised zone varies empirically with time like: $d=d_0 \exp[-(t-t_1)/t_2]$, where t_1 and t_2 depend on the power of the laser beam. Temperature calculations indicate that melting of the elemental constituents is probably involved in the transformation. (8 refs.)

109558 A method for calculating the extent of galvanic corrosion and cathodic protection in metal tubes assuming unidirectional current flow. D.J.Astley (IMI plc, Birmingham, England).

Corros. Sci. (GB), vol.23, no.8, p.801-32 (1983).

A simple procedure for calculating how galvanic corrosion and cathodic protection effects are distributed within metallic tubular systems carrying electrolytes is described. The procedure involves the use of equations which are analytical solutions and, in some instances, equations which require numerical solutions which can easily be effected using microcomputers. The equations are based on an assumption of unidirectional flow of electric current which is shown to be valid for appreciably conducting electrolytes, such as seawater. Various combinations of linear polarisation kinetics, Tafel law polarisation kinetics and totally diffusion-controlled kinetics can be used. Experimental verification of the procedure has been obtained using synthetic seawater for titanium and Cu-30Ni tubes in galvanic contact and for cathodically protected Cu-30Ni tube. It is proposed that the procedure could find useful application at the design stage of plant involving two or three different metals, or of cathodically protected pipework, when any necessary preventative measures indicated by an analysis could be adopted. (35 refs.)

109559 The solution composition and electrode potential in pits, crevices and cracks. A.Turnbull (NPL, Teddington, England).

Corros. Sci. (GB), vol.23, no.8, p.833-70 (1983).

The extent of information on the solution composition and electrode potential in pits, crevices and cracks has been reviewed. A brief description of the experimental techniques is followed by a detail summary of the experimental measurements on various metal/environment systems. For each system the potential in the cavity is compared with the external potential and the magnitude of the potential drop is discussed in terms of the polarization characteristics of the metal, the ease of mass transport, etc. The pH values in the cavities are interpreted on the basis of the nature of the electrode reactions in the cavity and the hydrolysis of dissolved metal cations. (83 refs.)

109560 Current distribution during the electrochemical corrosion protection of pipes. W.Schwenk (Mannesmann Forschungsinst. GmbH, Duisburg, Germany).

Corros. Sci. (GB), vol.23, no.8, p.871-86 (1983).

Summarizes some theoretical considerations about the current and potential distribution with cathodically protected pipes with respect to practical questions: (a) external protection and questions on the extent of the protection length, (b) internal current distribution behind an insulating unit due to d.c. voltage across this unit caused by external cathodic protection or by galvanic effects, and (c) current and potential distribution within a crevice due to external polarization. (6 refs.)

109561 The role of wedging stresses in the exfoliation corrosion of high strength aluminium alloys. M.J.Robinson (School of Industrial Sci., Cranfield, England).

Corros. Sci. (GB), vol.23, no.8, p.887-99 (1983).

The wedging stresses generated by the formation of insoluble corrosion products have been measured during the exfoliation corrosion of the high strength aluminium alloy L95. Stress intensity values obtained from double cantilever beam experiments, mathematical modelling and from observations of crack opening displacements are discussed with reference to the corrosion process. Exfoliation has effectively been prevented by applying compressive loading and it has been concluded that the degradation occurs by a stress corrosion mechanism. (11 refs.)

109562 The microstructure of the scale forming on dilute iron-silicon alloys in carbon dioxide. P.T.Moseley, G.Tappin, J.A.A.Crossley, J.C.Riviere (Materials Dev. Div., AERE, Harwell, England).

Corros. Sci. (GB), vol.23, no.8, p.901-20 (1983).

The information available relating to the microstructure of scale forming on dilute iron-silicon alloys ([Si]=0-1 $^w/_o$) in CO_2 (99%)/CO(1%) at 500°C has been supplemented by new analytical investigations involving X-ray diffraction, electron microscopy and X-ray photo-electron spectroscopy (XPS). X-ray diffraction from the underside of the scale has provided lattice parameter, strain and grain size measurements of the magnetite in the inner part of the duplex scale. Of these different sets of information the grain size shows by far the most dramatic dependence on alloy composition. The presence of 1.0 $^w/_o$ of silicon in the alloy brings a reduction in the grain size of the inner scale of more than an order of magnitude when compared with the scale on pure iron. A dry stripping technique has been developed which allows a thorough examination of the boundaries marking the inner and outer limits of the inner part of the scale. For the case of scales on Fe-1.0 Si it is found that the midscale interface, like that at the base of the scale, is marked by a local accumulation of silicon. (18 refs.)

109563 Conversion electron Mossbauer spectroscopy on the oxidation of a (110) Fe-57 single crystal 100 Å thick. M.Domke, B.Kyvelos (Inst. fur Atom- und Festkorperphys., Freie Univ. Berlin, Berlin, Germany).

Corros. Sci. (GB), vol.23, no.8, p.921-30 (1983).

Conversion electron Mossbauer spectroscopy (CEMS) has been used to measure the initial stages of oxidation on an 100 Å thick (110) Fe-57 single crystal face at 275°C in the pressure range from 2×10^{-4} to 8×10^{-3} torr. Only magnetite is formed at 2×10^{-4} and 8×10^{-3} torr, a magnetite/haematite conversion occurs at 2×10^{-3} torr. The various oxide phases have been investigated according to their growth behaviour and kinetics. Complicated changes in the kinetic behaviour are found with the magnetite/haematite conversion. Depth selective CEMS has been used to measure qualitatively the depth distribution of the oxide phases and the iron ion sites. (43 refs.)

109564 Blistering phenomena on lacquered mild steel. K.R.Gowers, J.D.Scantlebury (Corrosion & Protection Centre, Univ. of Manchester Inst. of Sci. & Technol., Manchester, England).

Corros. Sci. (GB), vol.23, no.9, p.935-42 (1983).

Concentrically divided mild steel panels were used as substrates underneath artificial paint blisters, and electrical current flow was measured between the concentric regions during immersion in sea water, using a zero resistance ammeter. It was demonstrated that currents do flow between different regions of steel substrate underneath a paint film, whilst it is corroding. Contamination of the blisters with sodium chloride was found to promote the corrosion processes and the current flow. Different types of corrosion processes were observed in the contaminated blisters, often with frequent movement of anodic and cathodic regions. In one instance, one of the contaminated artificial blisters grew to resemble a standard dome-shaped natural blister, and this was found to have a central anodic region surrounded by an outer cathodic region. (15 refs.)

109565 Constant strain-rate testing of AISI type 304 stainless steel in 0.5 M H_2SO_4+0.1 M NaCl solution at room temperature with controlled potential. R.J.L.Meyburg, J.M.Krougman, F.P.Ijsseling (Corrosion Lab., Royal Netherlands Naval Coll., Den Helder, Netherlands).

Corros. Sci. (GB), vol.23, no.9, p.943-57 (1983).

The constant strain-rate (CSR) test method has been applied to investigate the stress corrosion cracking (SCC) susceptibility of AISI type 304 stainless steel in 0.5 M H_2SO_4+0.1 M NaCl at 25°C within a range of controlled potentials. Cracks were found to form in two distinct potential regions: in the cathodic range, and in the passive potential region. A clear differentiation between the two observed types of cracks was attempted. Crack morphology, the measured current during straining and the reduction of area were used as criteria. SCC was found to occur essentially in the passive potential region; in the cathodic range the cracks were due to hydrogen embrittlement. (22 refs.)

109566 Strain-induced anodic dissolution of Cu single crystals—effects of specimen geometry and slip morphology. H.Niwa, S.Asawa, S.Haruyama, T.Mori (Tokyo Inst. of Technol., Yokohama, Japan).

Corros. Sci. (GB), vol.23, no.9, p.959-68 (1983).

Specimen geometry with respect to slip deformation and slip morphology have been examined in a study of strain-induced anodic dissolution of Cu single crystals. It has been found that a sample, whose geometry leads to the largest exposure of fresh (111) slip planes onto the original surfaces, shows the largest anodic dissolution on straining. However, the amount and rate of dissolution are unaffected by slip morphology or dislocation density. It has been calculated that approximately seven layers of Cu atoms dissolve from the freshly formed active (111) planes until the planes become inactive. (9 refs.)

109567 An electrochemical study of phase-transitions in rust layers. M.Stratmann, K.Bohnenkamp, H.-J.Engell (Max-Planck-Inst. fur Eisenforschung GmbH, Dusseldorf, Germany).

Corros. Sci. (GB), vol.23, no.9, p.969-85 (1983).

Isolated rust layers have been investigated by electrochemical methods to find out whether their reduction and re-oxidation can affect the atmospheric corrosion of iron. At potentials below 0 mV, first a thin Fe^{2+}-containing surface layer is formed on top of the γ-FeOOH. This reduced surface layer can dissolve into the cell electrolyte at acid pH, or at lower potentials the Fe^{2+}-ions can react with γ-FeOOH to Fe_3O_4. The formation of magnetite could be followed by in-situ magnetic measurements. The reduced surface layer can easily be oxidized back to γ-FeOOH, magnetite can partly be oxidized to γ-Fe_2O_3. (39 refs.)

109568 Low temperature stress corrosion cracking of Inconel 600 under two different conditions of sensitization. R.Bandy, R.Roberge, R.C.Newman (Corrosion Sci. Group, Brookhaven Nat. Lab., Upton, NY, USA).

Corros. Sci. (GB), vol.23, no.9, p.995-1006 (1983).

The low temperature stress corrosion cracking (SCC) of Inconel 600 under two different conditions of sensitization was studied in sulfur-bearing environments. In one case the material was sensitized directly from the mill annealed condition (MAS) and in the other solution annealing followed by water quenching was used prior to sensitization (SAS). The propensity to SCC increased significantly by the SAS treatment, as revealed by dynamic tests in very dilute sodium thiosulfate or sodium tetrathionate solutions, and U-bend tests in a concentrated thiosulfate solution which failed to crack the MAS material. The implications of these observations are discussed in terms of the microstructures of the materials. (18 refs.)

109569 A computer analysis of electrochemical impedance data. M.W.Kendig, E.M.Meyer, G.Lindberg, F.Mansfeld (Rockwell Internat. Sci. Center, Thousand Oaks, CA, USA).

Corros. Sci. (GB), vol.23, no.9, p.1007-15 (1983).

CIRFIT, a computer analysis of electrochemical impedance data, minimizes the sum of squares of the radial difference between observed and calculated impedance data presented in either the complex impedance or admittance plane. CIRFIT requires no assumptions of ideal capacitive frequency response for the double layer in order to extract the values of solution resistance and polarization resistance that are important to corrosion rate analysis. Examples are presented of the use of CIRFIT for the analysis of corroding iron in tapwater and for model pit electrodes that have twotime constants in 0.5 M NaCl. (15 refs.)

109570 The oxidation behaviour of heat resisting metallic fibres. S.R.J.Saunders, I.Lefever (NPL, Teddington, England).

Corros. Sci. (GB), vol.23, no.9, p.1025-43 (1983).

The behaviour of 22 μm diameter alloy fibres of Type 310 stainless steel, Hastelloy X, Inconel 601, and Fecralloy has been studied at 600°C in combustion gases with and without HCl addition. Chromia-forming alloys exhibited higher rates of attack than would have been expected from a consideration of the properties of the bulk material whereas normal rates of attack were observed for alumina-forming alloys. The addition of HCl to the combustion gases increased rates of attack for all alloys and generally this was associated with increased sulphur in the oxide layer. The results are discussed with reference to the unusual geometry of the samples, and it is suggested that the direction of motion of the ions in the growing oxide layer is an important factor governing its protective nature. Alloy depletion effects were also noted, particularly for some Fecralloy samples which were pre-oxidized before exposure, and this may cause eventual failure of the protective oxide. (8 refs.)

109571 Protection potentials for pitting of stainless steel in neutral chloride solutions. R.C.Newman (Corrosion Sci. Group, Brookhaven Nat. Lab., Upton, NY, USA).

Corros. Sci. (GB), vol.23, no.9, p.1045-6 (1983).

Azzerri et al. (see ibid., vol.22, p.675, 1982) have recently measured protection potentials for pitting of Type 304 stainless steel in neutral sodium chloride solutions. They suggest that the protection potential E_p is given by: $E_p \simeq A - B\log c$ where c is the molar concentration of sodium chloride and B is about 0.12 V/decade at 22°C. However, the data show that E_p tends to approach a constant value for $c \lesssim 0.15$ M. The correlation with the equation is therefore poor. The assumption is explored that protection corresponds to passivation at a critical interfacial concentration of dissolution products M^{n+}. This is equivalent to a critical pH, and roughly equivalent to a critical current density for a given pit geometry. (2 refs.)

109572 Some preliminary experiments regarding the corrosion inhibition of a carbon steel by oleylamino-propylene amine with tri (methyl-phosphonic) acid. M.Duprat, F.Moran, F.Dabosi (Lab. de Metall. Phys., ERA, CNRS, Toulouse, France).
Corros. Sci. (GB), vol.23, no.9, p.1047-50 (1983).
It has been reported (see Corrosion, vol.36, p.262, 1981) that the association of oleylamino-propylene amine and amino-tri [methyl-phosphonic] acid (FA+TMPA) exhibits good inhibitive properties against the corrosion of a carbon steel in an aerated 3% sodium chloride solution. It has been shown that this selective composition appears to be one of the best of its type for avoiding both problems of scaling and/or corrosion. The authors report preliminary results of rotating disc electrode experiments using both steady-state and transient electrochemical techniques to study the protection mechanism. (5 refs.)

109573 Long-term corrosion tests of materials for thermal decomposition of sulphuric acid. F.Coen-Porisini (Comm. of the European Communities Joint Res. Centre, Ispra, Italy).
Int. J. Hydrogen Energy (GB), vol.8, no.10, p.819-28 (1983).
The corrosion resistance of tubes of Incoloy 800 and AISI 310 SS has been studied in a mixture of air and H_2SO_4 vapours at 1 bar pressured. The duration of the test was one year (8500 h). The temperatures of the tubes ranged from 400 to 700°C for SS AISI 310 and from 400 to 900°C for Incoloy 800. The extent of the attack was determined by measuring the scale thickness and the penetration depth on cross-sections of samples taken from several zones of the tubes. X-ray diffraction and SEM X-ray microanalysis techniques were used. (18 refs.)

109574 Effect of cold work on anodic polarization of low carbon steel. A.M.Shamseldin, J.M.Abd Elkader, F.M.Abd El Wahab, H.S.Hegazy (Lab. of Electrochem. & Corrosion, Nat. Res. Centre, Cairo, Egypt).
J. Mater. Sci. (GB), vol.18, no.9, p.2732-42 (Sept. 1983).
Carbon steel nails prepared by deep drawing exhibit grains elongated in the direction of swaging. They are also characterized by high corrosion rates, as measured potentiodynamically in 0.1 M H_2SO_4. Normalization of grain dimensions and reduction in the corrosion rate are achieved through annealing. Treatment at 750°C for 2 h is effective in producing strain-free specimens with rounded grains. Extended heat treatment at this temperature causes the development of larger grains and the improvement in the corrosion behaviour of the alloy. 'As-received' and strain-free specimens are subjected to controlled tensile or torsional cold work. In all cases deformation results in an increase in the susceptibility of the alloy to undergo attack. The rate of corrosion increases greatly when the deformed steel corrodes in Cl^- ion containing media. Both general and pitting corrosion are operative. (21 refs.)

109575 High-performance Ni-Cr-Mo-W alloys. H.M.Tawancy, R.B.Herchenroeder, A.I.Asphahani (Technol. Dept., Cabot Corp., Kokomo, IN, USA).
J. Met. (USA), vol.35, no.6, p.37-43 (June 1983).
The Ni-Cr-Mo-W system is re-examined in view of its importance to industrial applications involving aqueous corrosion. Historical development of the system is presented, and its physical metallurgy is examined in terms of secondary precipitates and long-range ordering. The role of alloying elements is explained in terms of thermal stability and environmental resistance. Finally, the future of the Ni-Cr-Mo-W system is explored. (29 refs.)

109576 Stress generation behaviour in Cu_2O scales during thermal oxidation. Yung-ju Pyun, T.Homma (Inst. of Industrial Sci., Univ. of Tokyo, Tokyo, Japan), K.Takakuwa.
J. Jpn. Inst. Met. (Japan), vol.47, no.8, p.663-70 (Aug. 1983). In Japanese.
The stress generation behavior in Cu_2O grown on Cu has been studied using an X-ray diffraction apparatus, which is provided with a newly designed hot stage unit. The oxidation run has been carried out at temperatures between 573 and 923K and at oxygen pressures ranging from 24 to 110 Pa for (100) and (111) faces of single crystalline copper discs and surfaces of polycrystalline ones. The stress generation behavior varied depending on temperature and crystalline state of the specimen. At temperatures below the half of the melting point of Cu_2O a compressive strain (7×10^{-3} at 573K) larger than the fracture strain of the bulk oxide (2×10^{-3}) was observed. This elastic strain diminished at higher temperatures. The oxide scale exhibited a pseudo brittle-ductile transformation between 573-673K. A quantitative evaluation of the stress generated in the epitaxial oxide grown on Cu (100) showed values between 1.3 and $3.0 \pm 0.5 \times 10^8$ Nem^{-2}, which were 30% larger than the elastic strain generated in the oxide grown on Cu (111). (29 refs.)

109577 Growth and distribution of microcracks at the surface of smooth specimen of 304 stainless steel in creep and effect of high temperature oxidation. R.Ohtani (Faculty of Engng., Kyoto Univ., Kyoto, Japan), S.Nakayama.
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.635-9 (June 1983). In Japanese.
A continuous observation was made of intergranular microcrack growth at the surface of smooth specimens of 304 stainless steel during creep tests at 650°C in air and in vacuum. It was found that the effect of environment was different depending upon the stress value. That is, at high stress, the rupture time was shortened by intergranular oxidation, and on the contrary at low stress, it was lengthened by the formed oxide film which has protective and restorative actions. It was shown that the microcrack growth behavior in creep was explainable on the basis of the Weibull distribution of crack length. (5 refs.)

109578 Titanium α-nitrogen solid solution formed by high temperature nitriding: diffusion of nitrogen, hardness, and crystallographic parameters. J.-P.Bars (Inst. Nat. des Sci. Appliquees de Rennes, Rennes, France), D.David, E.Etchessahar, J.Debuigne.
Metall. Trans. A (USA), vol.14A, no.8, p.1537-43 (Aug. 1983).
The nitriding of titanium by nitrogen has been carried out at 1350°C and 1450°C, and the nitrogen concentrations at different levels in the α-phase layer determined by direct analysis, using the $^{14}N(d,\alpha)^{12}C$ nuclear reaction. The concentrations at the α/ϵ interface agree with the published phase diagram, but a significant deviation is observed at the α/β interface. The diffusion coefficients were calculated from the experimentally obtained profiles and were found to agree well with those calculated using a simple model describing the nitriding reaction. The crystallographic parameters of the HCP titanium α-nitrogen solid solutions were determined and showed evidence of a cooperative effect in the deformation of the crystallographic interstices. Vickers microhardness was measured with a 100 g load for nitrogen concentrations above 10 at. pct. (17 refs.)

109579 Sensitization of 12 wt pct chromium, titanium-stabilized ferritic stainless steel. T.M.Devine, A.m.Ritter (Corporate Res. & Dev. Center, General Electric Co., Schenectady, NY, USA).
Metall. Trans. A (USA), vol.14A, no.8, p.1721-8 (Aug. 1983).
The sensitization behaviours of 19 heats of titanium stabilized, 12 wt.% chromium, ferrite stainless steel were evaluated by measuring the intergranular corrosion resistance of samples given a two-step heat treatment. The latter consisted of a one-hour high temperature exposure followed by a water quench and one of 19 different low temperature treatments. The results indicate that heat treating at temperatures $\gtrsim$1000°C produces a microstructure which can be sensitized by subsequent aging at temperatures $\lesssim$600°C. The amount of carbon and not the amount of nitrogen nor the amount of carbon plus nitrogen dictated the sensitization resistant of the titanium-stabilized, 12 wt.% chromium alloy. The proposed mechanism of sensitization in these alloys suggests that during the high temperature exposure, the titanium carbonitrides decompose, freeing carbon or carbon and nitrogen into interstitial solid solution. During subsequent heat treating at temperatures $\lesssim$600°C, chromium-containing carbides, precipitate intergranularly, and a chromium-depleted zone is formed along the grain boundaries. (20 refs.)

109580 On the corrosion fatigue behavior of a modified SAE 4135 type steel in a H_2S environment. K.Tsukada, K.Minakawa, A.J.McEvily (Univ. of Connecticut, Storrs, CT, USA).
Metall. Trans. A (USA), vol.14A, no.8, p.1737-42 (Aug. 1983).
The corrosion fatigue behaviour of a modified SAE 4135 steel in a H_2S environment is compared to that of a standard SAE 4135 steel of the same strength level. The modification consists of an increase in molybdenum content from 0.20 to 0.75% and the addition of 0.036% columbium. It was found that the high cycle fatigue strength of the modified steel was 66% higher than that of the standard steel. The improvement is attributed to an increase in resistance to hydrogen embrittlement brought about by a higher tempering temperature which reduces the amount of phosphorous on grain boundaries, as well as the beneficial scavenging effects associated with the increase in molybdenum content and the presence of columbium. (13 refs.)

109581 Study of the possibility of liquid boriding of high-speed steels. E.A.Smol'nikov, L.M.Sarmanova (All-Union Sci.-Res. Tool Inst., VNII, USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.785-8 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.30-2 (Nov. 1982).
A study was made of low and high-temperature boriding of steels R6M5 (standard composition), 11R3AM3F2 (1.05% C; 2.9% Mo; 3.9% Cr; 2.5% V), and 9M3F2S (0.9% C; 5.5% Cr; 3.3% Mo; 2.2% V; 1.2% Si). It is concluded that a beneficial effect of boriding may be expected only on a tool which is made of steel having a hardening temperature not above 1080°C and the technical specifications of which do not have a ground shape. For high-speed steels it is apparently only possible to subject those tools to boriding for which red hardness is not obligatory (e.g. certain components of special bearings) and for which fusion of the cutting edge is acceptable (e.g. certain types of cutters). For the rest of the objects made of high-speed steels boriding is unsuitable. (2 refs.)

109582 Effect of ultrasonics on the properties of hardened high-speed steel R6M5. V.A.Sushchikh, K.M.Pogodina-Alekseeva, V.S.Biront (Krasnoyarsk Inst. of Nonferrous Metals, Krasnoyarsk, USSR).
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.789-93 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.11, p.32-5 (Nov. 1982).
Prismatic specimens $2.5 \times 6 \times 60$ mm in size, drills 7 and 20.5 mm in diameter, and end mills 20.54 mm in diameter made of steel R6M5 were subjected to UST. The action of ultrasonic treatment for hardened high-speed steel R6M5 with optimum treatment schedules ($\sigma_p = 164$ MPa, $\tau = 10$ min) lead to a reduction in first order residual stresses by $\sim$20%. Subsequent single and two-stage tempering of steel R6M5 at 555 ± 5°C made it possible to increase hardness by HRC 1.5-2.0 and the ultimate bending strength by 400-600 MPa. (7 refs.)

109583 Failure of stainless steels in contact with tin-phosphorus bronze. E.V.Vasil'eva, M.I.Trekina, N.S.Artemenko, I.I.Yurkov.
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.859-62 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.12, p.47-9 (Dec. 1982).
It was found that sintering of bronze filters is accompanied by complex interactions of the mold material (steel 12Kh18N9T) with the filter material (bronze Br0F10-1), the most important of which are oxidation of the surface of the mold and interdiffusion of the components. Oxidation of steel 12Kh18N9T under these sintering conditions is accompanied by oxidation of chromium, which leads to impoverishment of the surface in chromium and the development of a zone of internal oxidation. The diffusional penetration of the filter components—copper, tin, and phosphorus—into the mold in the process of sintering is accompanied by alloying of these elements with the basic mold material (iron) and leads to further reduction of its oxidation resistance. Especially harmful is simultaneous alloying with copper and phosphorus. (1 ref.)

109584 Surface composition of stainless steel at active corrosion. T.Hakkarainen, I.Olefjord (Chalmers Univ. of Technol., Goteborg, Sweden).
Phys. Scr. (Sweden), vol.T4, p.189-93 (1983). (Nordic Conference on Surface Science, Tampere, Finland, 18-20 Aug. 1982).
X-ray photo-electron spectroscopy was used to study the surface compositions of stainless steel (AISI 304) after active corrosion in 2.5 M H_2SO_4 or 2.5 M H_2SO_4+0.5 M NaCl solutions under electrochemically controlled conditions. Using two models with different assumptions about the element distributions, possible concentration profiles for Fe, Cr, Ni, Mo and Cu in their metallic and oxidized states were evaluated. It was concluded that Ni, Cu and Mo are enriched in their metallic states on the surface, possibly mainly on separate surface regions not containing Fe and Cr. (4 refs.)

109585 Examination of solid-phase transformations in the surface layers of titanium. A.P.Brovko, I.N.Bekman.
Russ. Metall. (GB), no.1, p.82-5 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.95-8 (1982).
Solid-phase processes in thin oxide surface layers on titanium have been studied by the radioactive gas-tracer method in the 20-1000°C temperature range with a linear heating regime. The main mechanism responsible for radon release on heating is bulk undisturbed diffusion associated with metal-iron self-diffusion. Solid-phase processes occurring in the oxide layer of the metal during heating (dehydration, phase changes, oxidation, nitriding, etc.) are reflected in the thermodesorption spectrum as additional peaks. Depending on the experimental conditions, various types of oxide layers can exist on the titanium surface. (8 refs.)

109586 Examination of the high-temperature oxidation of Ni-Re alloys. E.M.Lazarev, N.A.Korotkov, E.P.Arskaya, R.A.Miliyevskiy.
Russ. Metall. (GB), no.1, p.93-6 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.105-9 (1982).
Small additions of rhenium (up to 10 wt.%) have virtually no effect on the rate of oxidation of nickel at 1000-1200°C. Oxidation in the Ni alloy with 25% Re is about half that of plain nickel. In all these alloys the scale consisted of two layers: a top layer of NiO and underneath it a layer of mixture of NiO and ReO_2, which is due to the low permeability of rhenium through the nickel oxide. There is two-sided diffusion in the oxidation of Ni-Re alloys: diffusion of nickel to the outside of the scale and of oxygen into the alloy, which cause a lower layer of scale and a zone of internal oxidation to appear. (10 refs.)

109587 Influence of lanthanum, titanium and niobium on the heat resistance of a chromium nickel alloy in air and combustion products of fuel oil. M.V.Pridantsev, A.M.Samarina, M.P.Matveyeva.
Russ. Metall. (GB), no.1, p.97-100 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.110-14 (1982).
Alloying of the alloy 40Ni-60Cr with small additions ($\leq 2\%$) of lanthanum, titanium or niobium noticeably decreases the velocity of its oxidation in air at high temperatures (1000-1100°C), thus there are optimum concentrations of alloying elements securing the maximum heat resistance of the alloys. Scale forming on the oxidation of low-alloyed alloys in air consists of Cr_2O_3. With an increasing concentration of lanthanum, titanium or niobium, their simple or complex oxides are formed in the scale and the protective properties of the scale deteriorate. The corrosion resistance of chromium-nickel alloys with a high chromium content in the products of combustion of a high sulphur fuel oil is higher than that of industrial heat resistant alloys. (12 refs.)

109588 Growth of a system of interacting pores when a metal is saturated by hydrogen (hydrogen corrosion). K.A.Guriyev, B.Ya.Lyubov.
Russ. Metall. (GB), no.2, p.155-8 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.172-5 (1982).
The growth of a system of pores in the case of hydrogen corrosion is considered when the flow of diffusing substance into the pores cannot be considered as a small correction to the diffusion. (2 refs.)

109589 Numerical calculation of the decarburisation of medium and high carbon steels at temperatures below the A_1 point. E.L.Gyulikhandanov, S.N.Provotorov.
Russ. Metall. (GB), no.2, p.158-61 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.175-7 (1982).
Numerical simulation was used to analyse the kinetics of decarburisation in medium and high carbon steels below the A_1 point in the presence of carbide segregations. The number and size of the carbide segregations, and the rate of the chemical reaction between the gas medium and the surface have a substantial effect on the kinetics of carbon diffusion in the ferrite. (6 refs.)

109590 Oxidation resistance of high-nitrogen CrMn steels with silicon. O.A.Bannykh, V.M.Blinov, I.L.Poymenov, Ts.V.Rashev, Ch.A.Andreev, M.D.Manchev.
Russ. Metall. (GB), no.2, p.162-6 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.178-83 (1982).
The relationship governing the oxidation and formation of scale on high-nitrogen Cr-Mn steels with silicon have been examined. The oxidation resistance of these steels at temperatures up to 900°C is determined mainly by the protective properties of the thin layer of silicon oxide, whereas at higher temperatures it is controlled by chromium- and iron-base spinel phases. High-strength nonmagnetic Cr-Mn steels of the Kh18AG14S2 type with a higher nitrogen (0.3-1.65%) and silicon (2-3%) content can be classified on the basis of their resistance to oxidation in air as oxidation-resistant materials for service at temperatures from 700 to 1000°C. (8 refs.)

109591 Features of growth of interference-coloured oxide films in air on titanium alloy VT5. O.L.Kirillova, E.S.Vorontsov, Yu.V.Spichkin.
Russ. Metall. (GB), no.2, p.166-9 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.183-6 (1982).
The growth of oxide films on the titanium alloy VT5 was investigated using the interference patterns supplemented by ellipsometric measurements, metallographic, electronographic and micro-X-ray analyses. Using the differential method of analysis, a substantial change was detected in the activation energy during the oxidation: the value of E increases with increasing thickness of the oxide film. The existence of a special anisotropy of growth of oxide film, caused by the direction of deformation of the metal (rolling) was established. (5 refs.)

109592 Corrosion resistance of alloys based on titanium in solutions of hydrochloric acid, sodium chloride and hydroxide. S.N.Mandzhagaladze, M.P.Mikaberidze, T.T.Nartova, I.N.Lordkipanidze, D.N.Pirtskhalava.
Russ. Metall. (GB), no.2, p.169-72 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.2, p.186-9 (1982).
The influence of copper and nickel on the corrosion resistance and electrochemical properties of titanium in solutions of hydrochloric acid, sodium chloride and hydroxide was studied. Additions of copper in amounts of 0.35-5% lowers the corrosion resistance of titanium in solutions of hydrochloric acid, sodium chloride and hydroxide. In all the solutions investigated, copper has no practical influence on the development of the cathode process and increases the anodic currents. Introduction of nickel into titanium increases its resistance to corrosion in hydrochloric acid sodium chloride and hydroxide solutions. The minimum velocities of solution are observed for the titanium alloy with 8% Ni. (6 refs.)

109593 Surface films and rate of dissolution. I.A.Kakovskiy, L.D.Sheveleva.
Russ. Metall. (GB), no.3, p.40-2 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.3, p.43-7 (1982).
The deleterious influence of surface films on the rate of heterogeneous processes has been demonstrated. Formation of surface films is often linked with the occurrence of parallel-series or side reactions. The criterion for assessing the influence of films chosen is the ratio of the experimental and theoretical rate constants. The harmful influence of films can be eliminated in various ways that depend on the composition and character of the film. (18 refs.)

109594 Effect of lanthanum, yttrium, titanium, zirconium and boron on the high-temperature properties of chromium-nickel alloys in various environments. M.V.Pridantsev, M.P.Matveyeva, E.M.Lazarev, V.A.Morozov, A.M.Samarina.
Russ. Metall. (GB), no.3, p.57-63 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.3, p.60-8 (1982).
Alloying of alloy 40Ni-60Cr with small amounts of boron, lanthanum, yttrium, titanium and zirconium markedly reduce its oxidation rate in air, particularly at high temperatures. Alloying with the rare-earth elements is the most effective. The heat-resistance of chromium-nickel alloys in natural gas combustion products is higher than in air. Scale formed on oxidation of alloys in air or on reaction of the alloys with natural gas combustion products consists of chromium oxide Cr_2O_3. The corrosion resistance of chromium-nickel alloys with high chromium content in the combustion products from high-sulphur fuel oil is higher than that of commercial heat-resistant alloys. Alloying of alloy 40Ni-60Cr with small amounts of lanthanum or titanium increases its corrosion resistance by 5-15%. Small additions of boron, lanthanum, yttrium, titanium and zirconium markedly increase the ductility of alloy 40Ni-60Cr without substantially reducing its heat-resistance. (27 refs.)

109595 Reconsideration of the superposition model for environmentally assisted fatigue crack growth. R.P.Wei, Ming Gao (Lehigh Univ., Bethlehem, PA, USA).
Scr. Metall. (USA), vol.17, no.7, p.959-62 (July 1983).
A modification of the superposition model for environmentally assisted fatigue crack growth (corrosion fatigue) is proposed. The modification gives explicit recognition to the fact that mechanical (or 'pure') fatigue and corrosion fatigue can proceed by different micromechanisms and in parallel. The modified model provides a rational basis for considering the role of microstructure in corrosion fatigue. Preliminary fractographic evidence provides support for this modification. (10 refs.)

109596 Effect of palladium additions to AISI 4130 steel on its sulfide cracking susceptibility. J.B.Lumsden (Rockwell Internat. Sci. Center, Thousand Oaks, CA, USA), B.E.Wilde, P.J.Stocker.
Scr. Metall. (USA), vol.17, no.8, p.971-4 (Aug. 1983).
Describes work on high strength steels aimed at decreasing the penetration of hydrogen or rendering the adsorbed hydrogen innocuous. Palladium metal markedly enhances the recombination kinetics of adsorbed hydrogen and also has the ability of absorbing large quantities of hydrogen. An investigation was undertaken to determine the effects of palladium additions to AISI 4130 steel on its sulfide stress cracking susceptibility and to correlate these effects to changes in the composition and morphology of sulfide inclusions. (14 refs.)

109597 Creep and stress rupture strength of 5VMTs alloy clad with VN7 alloy. I.S.Tsvilyuk, V.I.Pyl'nikov (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.10, p.1385-8 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.85-9 (Oct. 1982). [received: Sept. 1983]
Presents the results of investigations of the creep and short-term and stress-rupture strengths of VN7-5VMTs-VN7 clad sheet and also data on comparison of the characteristics considered for this sheet and for 5VMTs niobium base alloy. It was found that 5VMTs alloy clad with VN7 alloy possessed an advantage in short-term properties over 5VMTs alloy up to 1300°C, but was substantially inferior to the latter in stress rupture strength characteristics in the 1000-1400°C test-temperature range. (4 refs.)

109598 Morphological study of porous PbO_2 formed in aqueous H_2SO_4 on Pb-Sb and Ca-Sn-Pb alloys. J.A.Bialacki, N.A.Hampson (Chem. Dept., Univ. of Technol., Loughborough, England), K.Julian.
Surf. Technol. (Switzerland), vol.19, no.4, p.347-53 (Aug. 1983).
A morphological study of the PbO_2 matrix formed by the oxidation of pasted Pb-Sb and Ca-Sn-Pb electrodes in 0.3M H_2SO_4 and then subjected to microcomputer-controlled potentiostatic pulse experiments in 5 M H_2SO_4 is presented. After a reductive pulse into the $PbSO_4$ region, a complete discharge and a re-step back into the PbO_2 region, it was found that with the Pb-Sb 'positive' a considerable amount of α-PbO_2 was produced. This was very different from the case of the Ca-Sn-Pb-supported PbO_2 matrix where β-PbO_2 was predominantly formed. (6 refs.)

109599 Cavitation erosion of cast iron in 3% salt water. T.Okada, Y.Iwai (Dept. of Mech. Engng., Fukui Univ., Fukui, Japan), A.Yamamoto.
Wear (Switzerland), vol.88, no.2, p.167-79 (1 July 1983).
Vibratory cavitation erosion tests were performed on cast irons and steels in 3% salt water, and the results were compared with previous finding in ion-exchanged water. The ratio of the mass loss rate in 3% salt water to that in ion-exchanged water is greater for pearlitic than ferritic cast irons. It is also greater for spheroidal graphite than for gray cast iron. These results are explained by the increased number and/or average length of erosion cracks in 3% salt water. The erosion resistances of cast irons and steels in 3% salt water do not improve with increasing values of $H_v^2/E\beta_g$ (where β_g is the fatigue strength reduction factor for cast iron) as expected from those in ion-exchanged water. In 3% salt water, cast irons show only one-half the erosion resistance of steels with the same value of $H_v^2/E\beta_g$. The relation that the mass loss rate is proportional to the *n*th power of the horn amplitude was observed. However, the exponent *n* is smallest for the pearlitic materials in corrosive liquid. (6 refs.)

109600 Can you weld to avoid corrosion?. R.Brosilow.
Weld. Des. & Fabr. (USA), vol.55, no.9, p.67-74 (Sept. 1982). [received: July 1983]
Presents a survey of the causes of corrosion with particular emphasis on corrosion in welds. (no refs.)

109601 Investigation and analysis of corrosion phenomena in coated precious metal contact materials. H.Graichen, G.Oertel, H.Sommer, R.Voigtmann, C.Weissmantel (Tech. Hochschule Karl-Marx-Stadt, Sektion Phys./Elektronische Bauelemente, Karl-Marx-Stadt, Germany).
Z. Phys. Chem., Leipzig (Germany), vol.264, no.4, p.645-63 (1983). In German.
In order to investigate the corrosion resistance, samples of galvanically coated contact materials of the composition CuSn6/Au/Pd/Au were subjected in corrosion chambers to a test atmosphere containing H_2S, SO_2 and H_2O. Morphological changes were examined by scanning electron microscopy (SEM), and the corrosion products were analyzed—including depth profiling—by means of Auger electron spectroscopy, electron spectroscopy (ESCA) and secondary ion mass spectroscopy. From the results it can be concluded that the transport of copper (Cu) through the noble metal layers are rate-determining. (28 refs.)

109602 The inhibition of the intergranular corrosion of a sensitized stainless steel in hot acidic solutions. G.Trabanelli, A.Frignani, F.Zucchi, M.Zucchini (Corrosion Study Center 'A. Dacco', Univ. of Ferrara, Ferrara, Italy).
Z. Phys. Chem., Leipzig (Germany), vol.264, no.4, p.813-26 (1983). In German.
Some different types of organic substances (an acetylenic derivative, and sulphur- or nitrogen-containing additives) were tested as inhibitors for the intergranular corrosion of sensitized AISI 304 stainless steel in diluted sulphuric or sulphamic acid solutions at 70°C. Among the different organic substances examined, the sole compounds able to stop the intergranular attack are those containing a sulphur atom with its electronic lone pair free. These inhibitors perform their action by reducing the differences of the corrosion rate between the chromium depleted grain-boundaries and the matrix. As some of the tested inhibitors could decompose with the formation of HS^-(or H_2S), the influence exerted by HS^- ion on the corrosion process is evaluated. (23 refs.)

109603 Mesure continue de l'epaisseur des revetements sur les toles (Continuous measurement of the thickness of coatings on metal sheets). J.Lebailly, R.Pirlet.
Report EUR 8122 FR, Comm. European Communities, Luxembourg (1983), 40 pp. In French. Contract 7210.GA/205.
Following a study of the literature relating to methods and devices for measuring the thickness of coatings, the research was devoted to the development of a suitable equipment for on-line measurements on coated metal sheets. Firstly, a method based on the infrared spectral reflectivity of the materials proved to be unsuitable. Work was then focused on designing a measuring device based on the variations in reluctance of a magnetic circuit including the coated sheet. The air gap between the measuring head and the coating is kept constant by a pneumatic device. The sensitivity of the equipment is 0.001 mm. The maximum accuracy is 0.003 mm in the range from 0.001 to 0.010 mm. The range of measurements can be extended up to 0.200 mm. A prototype unit was also constructed in order to apply this technology to an industrial production line. The system is applicable to non-magnetic solid coatings on magnetic substrates. (44 refs.)

109604 Submicron conductor array fabricated from a recrystallized eutectic thin film. H.E.Cline (General Electric Corporate Res. & Dev., Schenectady, NY, USA).
Laser-Solid Interactions and Transient Thermal Processing of Materials, Boston, MA, USA, 1-4 Nov. 1982 (New York, USA: Elsevier 1983), p.727-31
A submicron conductor array was fabricated without using lithography by selectively etching a recrystallized Al-Al_2Cu eutectic alloy thin film. The 2 micron thick eutectic films were deposited on glass substrates and directionally solidified with both a quartz-iodine lamp and a scanning laser at rates between 0.0016 and 0.14 cm/sec. The resulting structure consisted of alternate parallel stripes of the two eutectic phases with a spacing between 0.5 and 4 microns that was controlled by the solidification rate. An array of submicron Al-rich conductors was fabricated by selectively etching away the Al_2Cu phase. At solidification rates greater than 0.004 cm/sec using the lamp heater the solid-liquid interface became non-planar while with the laser the structure was well aligned at the highest rates used, 0.14 cm/sec. At the maximum theoretical solidification rate that produces a two phase aligned eutectic structure the width of the Al wires would be 100 Å. (4 refs.)

81.70 MATERIALS TESTING

(inc. sample preparation for examination, metallographic techniques, ion and electron microprobe techniques, Auger and photoelectron techniques, defectoscopy; for measurement in the mechanics of solids and rheology, see 46.30R)

109605 Thermal wave remote and nondestructive inspection of polymers. G.Busse (Inst. fur Phys., Fachbereich Elektrotech., Hochschule der Bundeswehr Munchen, Neubiberg, Germany), P.Eyerer.
Appl. Phys. Lett. (USA), vol.43, no.4, p.355-7 (15 Aug. 1983).
Optically generated thermal waves propagating in various kinds of polymers (adhesives, coatings, fiber reinforced polybutyleneterephthalate, oriented polyethylene) are analyzed by photothermal detection. Some results from this remote technique are difficult to obtain by conventional methods. (17 refs.)

109606 Automatic monitoring of calculated life expiration of pressure parts. R.Pich, K.Erlmann (EVT Energie- und Verfahrenstech. GmbH, Stuttgart, Germany).
VGB Kraftwerkstech. (German Ed.) (Germany), vol.63, no.6, p.537-45 (June 1983). In German.
Introduces the computer-aided system 'FACOS' (fatigue control system) by means of which the calculated life expiration of critical components can be automatically monitored. Creep stress as well as alternating stress are thereby measured. For each component basis operating data in extremely condensed form are recorded and the accumulated life expiration and speed of life expiration are calculated. (43 refs.)

109607 High strain fatigue testing at elevated temperature. R.P.Skelton (Materials Branch, Central Electricity Res. Labs., Leatherhead, England).
Trans. Indian Inst. Met., vol.35, no.6, p.519-34 (Dec. 1982). [received: Aug. 1983]
Focuses upon the elevated temperature, high strain fatigue test. It explains the service cycle which the smooth specimen models and how the test stands in relation to other types of experiments. Push-pull, reverse bend and torsion deformation modes are considered and methods of strain measurement and control are compared, especially with regard to stress relaxation in creep/fatigue. After a discussion of cyclic hardening or softening in the initial stages (with attendant microstructural changes) leading to a steady-state hysteresis loop, the review moves on to total endurances and the various criteria for failure. It is shown how crack growth studies can provide an earlier indication of failure and several methods for crack growth measurement are examined. Much of the discussion concerns the low alloy ferritic and austenitic steels in the temperature range 500-700°C and some recent data on creep and environmental effects are presented. Finally it is shown how the newer asymmetrical cycling modes have permitted damage to be assessed from metallographic observation which in turn leads to the possibility of lifetime prediction. (98 refs.)

109608 Isolation, identification and determination of carbides in 11% chromium creep resistant steel. R.Kannan, S.R.Rajagopalan (Materials Sci. Div., Nat. Aeronautical Lab., Bangalore, India).
Trans. Indian Inst. Met., vol.35, no.6, p.568-71 (Dec. 1982). [received: Aug. 1983]
A composite scheme of chemical phase analysis for the isolation, identification and determination of the carbides (M_7 and M_{23} carbides) present in 11% chromium creep resistant steel is presented. Potentiostatic electrolytic technique in a non-aqueous solvent mixture was employed for the isolation of carbides. The isolated carbides were identified with scanning electron microscope in conjunction with an energy dispersive analyser. A composite scheme of spectrophotometric procedure was evolved for the chemical analysis of the isolated carbides of chromium, molybdenum and vanadium. (6 refs.)

109609 Interpretation of grain size descriptors. A.M.Gokhale (R&D Centre, Hindustan Brown Boveri Ltd., Baroda, India).
Trans. Indian Inst. Met., vol.35, no.6, p.595-600 (Dec. 1982). [received: Aug. 1983]
A rigorous geometrical interpretation of some important grain size descriptors is given. It is shown that the ASTM grain size number is related to the total grain edge length per unit volume. Thus the mean grain intercept (which is related to the total grain boundary surface area per unit volume) and the ASTM grain size number report different independent properties of the grain structure. (16 refs.)

109610 A tensile test apparatus for measurement of strain effect in high current compound superconductors. M.Umeda, H.Yamasaki, M.Watanabe (Electrotech. Lab., Ibaraki, Japan).
Bull. Electrotech. Lab. (Japan), vol.47, no.4, p.276-83 (1983). In Japanese.
A tensile test apparatus has been constructed for measurement of stress-strain diagrams and critical current degradation with strain in superconductors at the liquid helium temperature. The apparatus is designed to test high current Nb_3Sn multifilamentary superconductors, where load $L \leq 500$ kg, current $I \leq 1$ kA and magnetic field $B \leq 10T$. A bronze-processed superconductor including 38720 Nb_3Sn filaments, whose critical current density is 623 A/mm^2 at 9.5 T (without the Cu stabilizer) and critical current Ic is 880 A at 9.5 T, has been tested with the apparatus. Stress-strain relations and Ic degradation with strain have been precisely measured. (11 refs.)

109611 Synchrotron X-ray fractography: a novel technique for fracture-surface analysis. A.B.Hmelo, J.C.Bilello (Dept. of Materials Sci. & Engng., State Univ. of New York, Stony Brook, NY, USA), S.T.Davies, D.K.Bowen.
Mater. Lett. (Netherlands), vol.2, no.1, p.6-11 (July 1983).
Synchrotron X-ray fractography (SXRF), a new non-destructive technique for studying the subsurface microstructure of cleaved samples which allows correlation with the associated surface morphology is described. (11 refs.)

109612 Infrared imaging techniques for flaw detection in composite materials. R.Paulson, A.Aquino, H.Decker, T.Schapp (Lockheed Missiles & Space Co. Inc., Sunnyvale, CA, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.366, p.88-95 (1983). (Modern Utilization of Infrared Technology VIII, San Diego, CA, USA, 26-27 Aug. 1982).
With the development of the new super strength lightweight composite materials, flaw and void detection in the various layers have become of major importance. Special infrared imaging techniques have been developed to show these voids. Included in these nondestructive methods are active steady state, active pulsed, and fast recording with slow playback of infrared images. Emissivity correction techniques have also been considered. Considerable time can be saved by using an imaging system since the size and shape of a defect or

void is known at a glance. With video recording, documentation is achieved and further analysis is also possible without tieing up the part. Growth or changes of marginal flaws or voids can be traced during the manufacturing process, noting if they increase to the point of nonacceptance. An 8-13 μ infrared scanner compatible with a video recorder and a line integrator proved most effective. Colorizing the image also made the flaw visualization easier. (no refs.)

109613 A constant-velocity impact tester for brittle material. R.M.Frederiks (IBM Data Systems Div., Hopewell Junction, NY, USA).
Exp. Tech. (USA), vol.7, no.7, p.21 (July 1983).
A quality-control method was needed to determine the cracking susceptibility of different lots of glass. The constant velocity impact tester developed to perform this task consists of: an aluminum block with a precision hole; a pressure and vacuum hat; a mass housed and held in place by the vacuum hat; four vents in the block; and a photodiode light source and electronic-counter measuring setup. A structural bridge and stand hold and align the tester and specimen. The associated control and regulating equipment is illustrated. (no refs.)

109614 Computer controlled decreasing ΔK fatigue threshold test. R.S.Williams, P.K.Liaw, G.Peck (Westinghouse R&D Center, Pittsburg, PA, USA).
Eng. Fract. Mech. (GB), vol.18, no.5, p.953-64 (1983).
An automated fatigue threshold test was developed which decreases testing time, eliminates need for constant operator attention, and produces a plot of fatigue crack growth rate (FCGR) data as the test proceeds. A minicomputer interfaced to a servo-hydraulic test stand adjusts loads during the FCGR test to achieve a specified stress intensity range (ΔK). The value of ΔK is decreased exponentially with crack growth to get the fastest load shedding without crack arrest. The procedure is as follows: apply load levels to obtain desired ΔK for the crack length, a; using the specimen compliance, compute a new value for a; adjust loads to obtain corresponding ΔK for that a; record a, ΔK, and cycle count (N); repeat. Plots of a vs. N, and $\mathrm{d}a/\mathrm{d}N$ vs ΔK are made by a separate program. The optimized load shedding and 24 hr/day operation result in a considerable reduction in test time. The program was written in BASIC on a MTS Automated Test System. Visual crack growth measurements showed good agreement with computer acquired data for a test of ETP Cu. (7 refs.)

109615 An investigation of the blunting line. S.-W.Yin (Zhejiang Inst. of Technol., Hangzhou, China), R.A.Gerbrands, M.Hartevelt.
Eng. Fract. Mech. (GB), vol.18, no.5, p.1025-36 (1983).
Experimental evidence obtained on 3-point SENB specimens of carbon steel (St52-3) is used to compare ways of determining the slope of the 'blunting line' in J_{Ic} testing. The results demonstrate that the slope of the blunting line obtained by the stretched zone width (SZW) method is steeper than the blunting line predicted by the ASTM method. This results in lower values for both J_{Ic} and $(\Delta a)_c$ as determined with the SZW method, compared with those obtained by the ASTM method. The increased conservatism compared to the ASTM approach and the experimental evidence underlying it recommend the SZW method for further study. The subsequent widespread use expected for any recognized J_{Ic} determination seems to justify the additional effort and expenses associated with the SZW method. (15 refs.)

109616 Radiowave inspection of substances by the method of differential modulation of probe radiation. V.D.Iskin, L.F.Kuchin.
Elektron. Obrab. Mater. (USSR), no.3, p.73-5 (1983). In Russian. English translation in: *Electrochem. Ind. Process. & Biol. (GB)*
The device described permits broadening of the range of application of the method of differential modulation of a superhigh-frequency signal, and the use of this method for investigating the composition of substances and materials over a wide range of their physico-chemical properties. The principal component of the device is a differential cell consisting of a set of rigidly-fixed and eccentrically-arranged cylindrical sleeves. (4 refs.) *A.J.B.*

109617 Checking the breaking loads of silicate glass by recording the electromagnetic signal. V.A.Smirnov, V.P.Dmitriev, A.A.Vorob'ev, Yu.P.Malyshkov, V.F.Gordeev.
Glass & Ceram. (USA), vol.39, no.9-10, p.484-7 (Sept.-Oct. 1982). Translation of: *Steklo & Keram. (USSR)*, vol.39, no.10, p.10-11 (Oct. 1982).
Tests were conducted on three-layer specimens (triplex) that simulate the structural work under load. Continuous rolled silicate glass was used to manufacture the triplex. The specimens were a three-layer sheet measuring 100×100 mm, consisting of two layers of glass 6 mm thick each and a polymer gluing spacer between them 3-4 mm thick. Square plates of tempered silicate plate glass measuring 600×600×6 mm were used as models of large articles. The pulsed electromagnetic signal generated by the specimen was received by an electric antenna 3-5 mm from the surface of the specimen. The signal was amplified in the frequency band from 100 Hz to 1 MHz by a differential amplifier, was converted to DC voltage proportional to the number of pulses, and was recorded on photosensitive paper by a Neva MT loop oscillograph. It is concluded that the breaking load of articles of tempered and untempered silicate glass, including multilayer articles of large geometric dimensions and complex shape, can be tested by recording the pulsed electromagnetic signal generated by the articles during loading. (1 ref.)

109618 Detection of SiO_2 cracks with capacitance measurements. G.S.Hopper, D.W.Rich, W.B.Roush (IBM Corp., Armonk, NY, USA).
IBM Tech. Disclosure Bull. (USA), vol.26, no.2, p.634 (July 1983).
Describes a method to detect quartz defects between levels of metallisation via capacitance measurements. (no refs.)

109619 Test-site design for monitoring cracked SiO_2. G.S.Hopper, W.B.Roush (IBM Corp., Armonk, NY, USA).
IBM Tech. Disclosure Bull. (USA), vol.26, no.2, p.635-6 (July 1983).
A simple test structure, consisting of many contact pads connected to a silicon substrate and one contact pad connected to a large aluminum-copper plate which is isolated from the silicon substrate by standard SiO_2 underlay, provides a test site for monitoring cracked SiO_2 handling damage. (no refs.)

109620 Acoustic-emission study of crack formation in alloy steels under surfacing metal. S.N.Navolokin, E.G.Starchenko, A.A.Yudin (Sci.-Industrial Union for Machine-Construction Technol., Moscow, USSR).
Ind. Lab. (USA), vol.48, no.11, p.1127-31 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.62-5 (Nov. 1982).
The results are given of an acoustic-emission (AE) study of the nucleation of subsurfacing cracks (SSC) in alloy steels of the pearlite class in high-temperature annealing (550-650°C). The investigated grades of steel were 15Kh2NMFA, 10GN2MFA, and 15Kh2MFA. (4 refs.)

109621 Some problems in industrial ultrasonic weld inspection. V.E.Belyi, V.G.Shcherbinskii (Sci.-Inst. Union for Machine-Construction Technol., Moscow, USSR).
Ind. Lab. (USA), vol.48, no.11, p.1131-3 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.66-8 (Nov. 1982).
Some technical problems in the industrial ultrasonic inspection of welded joints and seams are discussed. The primary objective is to ensure adequately reliable flaw detection. (6 refs.)

109622 Acoustic flaw detector for inspecting multilayer structures. V.V.Murashov, N.N.Detinov.
Ind. Lab. (USA), vol.48, no.11, p.1134-7 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.68-70 (Nov. 1982).
A flaw-detector circuit is proposed is for inspecting multilayer structures in which the system composed of the radiator-product-receiver-amplifier operates in an oscillatory mode. A transducer containing radiating and receiving vibrators is placed on the surface of a product that is being inspected. Elastic vibrations of the product's surface that are excited by the radiator are converted by a piezoelectric receiver into electrical oscillations which enter the input of the amplifier. Then the voltage is supplied to the radiating vibrator which converts the electrical oscillations into mechanical vibrations. The elastic vibrations in the product are registered by a pointer-type indicator. (6 refs.)

109623 Nondestructive capacitive method of quality inspection for a cemented joint in a composite material. T.E.Shatksaya, V.I.Natrusov, N.V.Ivanova, R.A.Kamaletdinov.
Ind. Lab. (USA), vol.48, no.11, p.1137-8 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.70-1 (Nov. 1982).
A nondestructive capacitive method of inspection has been developed to estimate the strength of a cemented joint of fibreglass and a metal ceramic (mark S-2 silicon carbide) which are bonded with type 88N rubber cement. It is based on the property of a capacitor by which its capacity changes according to vibrations in the dielectric constant of a material under inspection that are due to flaws. (no refs.)

109624 Method for measuring the yielding of the testing system machine-specimen. L.T.Timoshuk, N.I.Nistratov (Bardon Central Sci. Res. Inst. of Ferrous Metall., USSR).
Ind. Lab. (USA), vol.48, no.11, p.1139-43 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.71-4 (Nov. 1982).
Experiments have shown that for metals having a physical yield point σ_T the value of this characteristic depends on the rate of tensile strain $\dot{\epsilon}_C$ in the yield stage. The comparability of σ_T values obtained for different metals is achieved in testing at the same speed $\dot{\epsilon}_C$ in the yield section. Speed $\dot{\epsilon}_C$ is linked with stress rate increase σ_A in the elastic stage and parameter K by the relation $\sigma_A=\dot{\epsilon}_C/(1/E+KF/L)$. If this condition is not satisfied an error in determining the physical yield point σ_T is introduced which can reach 10% of its nominal value. (5 refs.)

109625 Evaluation of residual stresses in welded joints of thin plate by a holographic method. A.A.Rassokha, N.N.Talalaev (Khar'kov Red Banner Airforce Engng. Acad., Khar'kov, Ukrainian SSR).
Ind. Lab. (USA), vol.48, no.11, p.1143-6 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.74-7 (Nov. 1982).
It is concluded that the holographic method can be used in the investigation of residual stresses in welded joints of thin plates produced by laser and argon-arc welding. Sufficiently simple calculation equations are developed for determining by a holographic method the residual stresses in plates with a two-dimensional residual stress system. The error in determining residual stresses by a holographic method decreases with increasing plate thickness if the stress system remains plane. The residual stress level in welded joints of plates made from 08Kh15N5D2T steel is close to the yield point both after argon-arc as well as after laser welding. (3 refs.)

109626 Photolithographic method for producing originals of small-base grids. V.A.Strizhak, A.A.Vainshtein, G.V.Khrenov.
Ind. Lab. (USA), vol.48, no.11, p.1147-8 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.77-8 (Nov. 1982).
Investigations of strain fields in the microstructure of high-tensile alloy steels (usually fine-grain steels) are carried out by means of small-base grids. The grid is applied to the specimen of the material being investigated by exposure from the original photo-template with grid image. The authors describe the method of making originals with a grid base of 10, 25, 50, and 100 μm. (3 refs.)

109627 Determination of mechanical characteristics of high-melting-point materials in bending. S.M.Barinov (Bardin Inst. of Metall., Acad. of Sci., USSR).
Ind. Lab. (USA), vol.48, no.11, p.1148-50 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.78-80 (Nov. 1982).
A simple method is described for the determination of strength and strain characteristics of high-melting-point materials in bending which requires no previous determination of μ or n in tension where N is the strain hardening coefficient, and n the exponent in the equation of creep rate as a function of stress. (2 refs.)

109628 Use of parabolic indentors for testing brittle materials by microimpression. T.S.Mikhailovskaya (Zhukov Khar'kov Aviation Inst., Khar'kov, Ukrainian SSR).
Ind. Lab. (USA), vol.48, no.11, p.1151-2 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.80-1 (Nov. 1982).
Analyzes the possibility of the use of a parabolic indentor for determining mechanical characteristics by microimpression. The indentors were made by electrochemical etching in an alternating current of plate tungsten blanks in a layer of 1 N NaOH solution electrolyte located on the surface of a bath with carbon tetrachloride. The tests were made on a PMT-3 tester equipped with specially prepared holders for conical and paraboloid indentors. The object of the investigation was zinc selenide, which is characterized by an increased tendency toward brittle fracture in connection with the presence of directed rigid covalent bonds. For comparison tests were made by microimpression with the use of standard pyramidal (angle at the tip 90°) and conical indentors. (4 refs.)

109629 A unit for creep testing with a capacitive strain sensor. A.P.Khinskii, L.A.Chernyshev.
Ind. Lab. (USA), vol.48, no.11, p.1153-5 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.81-3 (Nov. 1982).
A capacitive sensor, which is a flat differential condenser with a constant gap and a variable ratio of the areas of the plates, is used for continuous measurement of the deformation of a ring sample with high accuracy. Under otherwise equal conditions such as device makes it possible to double the sensitivity and area of linearity of the measured characteristic. It is possible to correct the form of the relationship of this characteristic by changing the configuration of the plates. The rotary plate of the capacitive sensor is

fastened to the loading lever, and the stationary plates are located on a stand. (4 refs.)

109630 Machine for investigating materials in tension in a magnetic field in the 4.2-300K temperature range. L.M.Volikova, V.K.Chernetskii, V.Ya.Il'ichev (Physicotech. Inst. for Low Temperatures, Acad. of Sci., Khar'kov, Ukrainian SSR).
Ind. Lab. (USA), vol.48, no.11, p.1156-8 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.83-4 (Nov. 1982).
A simple machine is described for investigating the mechanical properties of materials in tension in a magnetic field in the 4.2-300K temperature range with the following parameters: maximum load at room temperature 10 kN; strength of the magnetic field 2.387×10^6 A/m; solenoid inside diameter 35 mm; rate of deformation 0.005-50 mm/min. One of the significant disadvantages of the base machine is the axial play in the screw pair, creating at the moment of failure of the sample a marked distortion of the strain curve record. In order to eliminate this disadvantage the nut is fixed relative to the screw with a certain amount of axial interference with the use of special compensators. (10 refs.)

109631 Device for measuring axial and circumferential deformation in tubular specimens. A.G.Moiseev, O.L.Tolokonnikov (Tula Polytech. Inst., Tula, USSR).
Ind. Lab. (USA), vol.48, no.11, p.1158-60 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.85-6 (Nov. 1982).
A device is described for measuring the axial and circumferential deformation in the working zone of tubular specimens which are subjected to the simultaneous action of external pressures up to 1000 MPa (in a high-pressure chamber), axial tensile forces, and positive pressure differential within the specimen. The working principle of the device is the deformation of elastic elements with bonded resistance strain gages and the use of a slide-wire (rheochord-type) gauge. (no refs.)

109632 Rig for testing the mechanical and structural characteristics of paper. V.S.Simonov, V.N.Nepein, R.F.Valeev, V.P.Butyrin, I.A.Plotnikov (All Union Sci.-Res. Inst. for Cellulose Paper Industry, Perm', USSR).
Ind. Lab. (USA), vol.48, no.11, p.1160-3 (Nov. 1982). Translation of: *Zavod. Lab. (USSR)*, vol.48, no.11, p.86-8 (Nov. 1982).
The test consists of a device (type OSFP-1), amplifier, a power unit, a teraohmmeter (type E6-13), and two twin-coordinated recording potentiometers (type PDP4-02). The main feature of the rig is the specially designed OSFP-1 device which enables cyclic or continuous loading of the paper specimen and measurement of the force P, strain Δl, and electric resistance r in the test zone. (3 refs.)

109633 Recent developments in quantitative fractography. M.Coster, J.L.Chermant (Lab. de Cristallographie, Chimie, et Phys. des Solides, Univ. de Caen, Caen, France).
Int. Met. Rev. (GB), vol.28, no.4, p.228-50 (1983).
Following recent developments, quantitative image analysis of fracture surfaces has become an important feature in the process of obtaining a better knowledge of the microstructural processes involved during the deformation and rupture of materials. The authors illustrate and discuss (i) how a fracture surface can be reconstituted from stereographic views and profilometric methods of fracture analysis, and (ii) how to characterize morphologically a fracture surface and the relevant stereometric relationships that can be used. Finally, some examples from the literature of the use of these different methods are presented. (67 refs.)

109634 A TEM method for analyzing local strain fields in irradiated materials. J.I.Bennetch, W.A.Jesser (Dept. of Materials Sci., Univ. of Virginia, Charlottesville, VA, USA).
J. Nucl. Mater. (Netherlands), vol.117, p.303-7 (July 1983). (Proceedings of the Symposium on Radiation Damage Analysis for Fusion Reactors, St. Louis, MO, USA, 25-28 Oct. 1982).
Of great interest to the field of fracture mechanics is the strain field in front of a crack tip. In irradiated materials, cavities which naturally form as a result of radiation provide convenient internal markers. If a miniaturized irradiated tensile sample is pulled in situ in a transmission electron microscope (TEM), both the relative displacement of these cavities and their distortion in shape provide information on localized strain on a microscopic level. In addition, the TEM method allows direct correlation of active slip systems with crack propagation characteristics. To illustrate this method a strain field map was constructed about a crack propagating in a helium irradiated type 316 stainless steel sample containing large cavities. (16 refs.)

109635 Estimation of fatigue curves for steel specimens subjected to bending, axial and torsion loads. S.Subramanyan (Aveen's Univ., Montreal, Canada).
J. Inst. Eng. (India) Mech. Eng. Div., vol.63, pt.ME1, p.12-14 (July 1982). [received: Aug. 1983]
While empirical relationship for estimating fatigue curves in terms of tensile strength is available for unity stress ratio, no such simple method is available for other stress ratios. A method is proposed by approximating the curves in the Goodman diagram as straight lines. Equations are proposed to describe the fatigue curve in terms of stress ratio as well as mean stress values for bending, axial and torsion types of load. Equations have also been proposed for estimating the fatigue limit. These equations are verified for their validity with experimental data drawn from the literature and are found to be satisfactory. (2 refs.)

109636 A radioactive tracer method for measuring the relative surface areas of small samples. S.D.Brown, Tran Bao Van, G.P.Wirtz (Dept. of Ceramic Engng., Univ. of Illinois, Urbana, IL, USA).
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.C115-16 (July 1983).
A new method for measuring the relative surface area of small samples is described. The method is based on liquid-sorption theory and uses stearic acid tagged with ^{14}C. Relative surface area data on alumina samples deposited under various conditions by the anodic spark process are reported. The method was validated successfully using BET data taken on alumina samples. (12 refs.)

109637 Experimental study on accuracy of notch root strain evaluation equation of ASME B & PV C C N-47. Y.Ikemoto, S.Shimizu (Nuclear System Div., Kawasaki Heavy Industries, Ltd., Kawasaki, Japan), T.Kano, T.Udoguchi.
J. Soc. Mater. Sci. Jpn. (Japan), vol.32, no.357, p.615-19 (June 1983). In Japanese.
Describes the test results on strain concentration behaviour of type 304 stainless steel and $2^1/_4$Cr-1Mo steel. Type 304 stainless steel was tested at 600°C under cyclic displacement control and cyclic load control conditions, and $2^1/_4$Cr-1Mo steel was tested at 500°C under static creep condition. An improved fine grating method was developed utilizing photo spots in the indentations made by Vicker's hardness tester. The results of stain measurements were compared with the predictions by the equation given in ASME Code Case N-47 and the structural design guide for the Japanese fast breeder reactor. The equation was proved to give a conservative prediction. (4 refs.)

109638 Comparative tests of some electrochemical methods for evaluation of the susceptibility to intergranular corrosion. P.Novak, V.Cihal.
Kovove Mater. (Czechoslovakia), vol.21, no.4, p.461-6 (1983). In Russian.
The three electrochemical methods, chronopotentiometric, polarization potentiostatic and potentiokinetic in $HClO_4+Cl^-$ and H_2SO_4+KSCN solutions, are compared in relation to standardisation possibilities for testing of the resistance of stainless steels to intergranular corrosion. (3 refs.)

109639 Polar-Scan, a nondestructive test method for the inspection of layer orientation and stacking order in advanced fiber composites. W.H.M.van Dreumel, J.L.Speijer (Dept. of Aerospace Engng., Delft Univ. of Technol., Delft, Netherlands).
Mater. Eval. (USA), vol.41, no.9, p.1060-2 (Aug. 1983).
The ultrasonic scanning method, Polar-Scan is described. Its application to the nondestructive inspection of C fiber reinforced composite laminates used in the aerospace industry is discussed. Polar-Scan generates an image that can be considered a unique fingerprint of a specific laminate. (1 ref.)

109640 A critical commentary on magnetic particle inspection. D.J.Hagemaier (Douglas Aircraft Co., Long Beach, CA, USA).
Mater. Eval. (USA), vol.41, no.9, p.1063-8 (Aug. 1983).
During the past few years a number of steel parts have either failed or have been found cracked on in-service aircraft. Metallurgical evaluations of these parts revealed that, in all cases, the cracks initiated during fabrication, and some of them grew in service. A review of inspection records indicated that all the parts had received at least one magnetic particle inspection subsequent to the manufacturing operation that caused the cracks. An assessment of the situation indicated that the inspections were performed by inspectors, certified to national standards, at approved and qualified laboratories, using standard techniques and procedures. Hence, changes were needed in one or more of these areas to avoid this condition in the future. The author illustrates the cracked parts and describes the changes made to the conditions that allowed cracked parts to go undetected during the fabrication inspection. (1 ref.)

109641 The potential of real-time radiography for API 1104. S.A.Wenk (Southwest Res. Inst., San Antonio, TX, USA), R.A.Brokaw, R.G.Schonberg.
Mater. Eval. (USA), vol.41, no.9, p.1069-73 (Aug. 1983).
Discusses current and potential use of real-time radiography for examining piping welds governed by American Petroleum Institute (API) Standard 1104. A dissertation on the subjectivity of radiographic interpretation is included to compare real-time and film radiography. Also described is a video technique for sizing the through-wall dimension of weld defects for fitness-of-purpose as now permitted by Appendix A of API 1104. Illustrations of potential field applications are given. (4 refs.)

109642 Characterization of metals and alloys by electrical resistivity measurements. R.L.Cohen, K.W.West (Bell Labs., Holmdel, NJ, USA).
Mater. Eval. (USA), vol.41, no.9, p.1074-7 (Aug. 1983).
The authors have developed a four-point probe and measuring package that allow accurate measurements of the resistivity of metals in sheet or bulk form despite surface corrosion and other interfering effects. Measurements in a number of ferrous and nonferrous alloys are described. Several possible applications are suggested, especially in studying ferrous alloys. (9 refs.)

109643 Determination of Luders strains and flow properties in steels from hardness/microhardness tests. F.M.Haggag (Nuclear Safety Methods Div., EG&G Idaho Inc., Idaho Falls, ID, USA), G.E.Lucas.
Metall. Trans. A (USA), vol.14A, no.8, p.1607-13 (Aug. 1983).
Development of radiation tolerant materials for use in fusion reactors requires testing of small volumes of candidate materials in high energy neutron irradiation facilities. As part of an effort to develop methods for extracting mechanical property information from small specimens, the authors investigated techniques to characterize flow properties of steels exhibiting Luders strains from ball indentation hardness/microhardness tests. A quantitative relationship was found between the amount of pile-up formed during indentation and the magnitude of the Luders strain exhibitied during tensile testing in SAE 1015 steel. Moreover, by nonlinear regression analysis, a single set of equations was found which correlated hardness data to the homogeneous true-stress-true-plastic strain relationship of steels in a variety of metallurgical conditions in the strain range 1 to 10% at room temperature. (24 refs.)

109644 Evaluating the service reliability of metals and alloys. O.N.Romaniv.
Met. Sci. & Heat Treat. (USA), vol.24, no.11-12, p.835-41 (Nov.-Dec. 1982). Translation of: *Metalloved. & Term. Obrab. Met. (USSR)*, vol.24, no.12, p.6-13 (Dec. 1982).
Presents certain results of investigations conducted in the Ukraine in the area of development of methods of evaluating service reliability based on the determination of the crack resistance of metals and alloys, and also of investigations of the structure aspects of controlling the crack resistance of steels. (32 refs.)

109645 Checking the metallurgical condition of ferrous alloy parts by electromagnetic measurements. A.Stossel (Commissariat a l'Energie Atomique, CEN de Cadarache, Saint-Paul-lez-Durance, France).
Mem. & Etud. Sci. Rev. Metall. (France), vol.80, no.6, p.325-31 (June 1983). In French.
Relationships between both the electrical and magnetic properties of ferrous alloys and their metallurgical properties are obtained from analysis of the impedance. Practical examples are given; check on surface treatments: case-hardening, depth of quench. (no refs.)

109646 Non-destructive evaluation of the microstructure of hypoeutectic Al-Si foundry alloys AS7G03. B.Closset (Univ. McGill, Montreal, Canada), H.Oger, S.A.Argyropoulos, J.E.Gruzleski.
Mem. & Etud. Sci. Rev. Metall. (France), vol.80, no.6, p.333-43 (June 1983). In French.
A choice of two techniques is available for the non-destructive evaluation of the microstructure: determination of electrical resistivity and thermal analysis. Influence of strontium content, porosity and rate of solidification of the resistivity is discussed. (10 refs.)

109647 Analysis of acoustic emissions from polymers. D.Betteridge, P.A.Connors, T.Lilley, N.R.Shoko (Chem. Dept., Univ. Coll. Swansea, Swansea, Wales), M.E.A.Cudby, D.G.M.Wood.
Polymer (GB), vol.24, no.9, p.1206-12 (Sept. 1983).
Acoustic emissions obtained from polymers under stress have been subjected to various mathematical analyses with the objective of relating the observed signals to accompanying chemical and physical changes in the polymer. The following methods have been investigated: frequency analysis, autocorrelation analysis, cepstrum analysis and cluster analysis (pattern recognition). It is possible to classify the signals from a given polymer sample into relatively few types. There is a periodicity in a number of plots of acoustic power vs. time. Differences between samples are evident, although it is not possible at this

stage to state that they are statistically significant. The materials examined include, nylon-6,6, 'Diakon', polypropylene and various composites. (24 refs.)

109648 Metallographic methods of preparation and analysis of enameled layers. M.Schwarz (BASF AG, Ludwigshafen/Rhein, Germany).
Prakt. Metallogr. (Germany), vol.20, no.6, p.267-79 (June 1983). In German, English.
Metallographic analysis and documentation determines layer structure, pores, cracks, as well as shape, size, distribution and fraction of the phases in glass enamel and glass-ceramic composite systems. Microhardness measurements and etching behavior are indicators for the properties of the different phases. The composition of the phases can be established by SEM. The effect of tempering upon crystallization is demonstrated. The metallographic surface analysis and replica technique for an examination of the enamel layer on a structural part is illustrated. (6 refs.)

109649 Material-oriented preparation of sintered ceramic bodies. G.Hubner (Inst. fur Werkstofftech., Rosenthal AG, Selb, Germany), H.Hausner.
Prakt. Metallogr. (Germany), vol.20, no.6, p.289-96 (June 1983). In German, English.
The method and energy for preparation of ceramographic sections should be adapted to the goal of the investigation. Demands for quality of the mounts as well as the possibilities for preparation have increased substantially, while working periods have decreased markedly. Relief etching and tearout should be kept to a minimum since they can easily falsify the structure. Semi-automatic equipment and diamond grinding and polishing media are very helpful in producing ceramographic sections in a short time. It is possible to get good results also without these measures, but often they require a multiple in time and experience. (11 refs.)

109650 An improved technique for the macrophotography of cracked steel specimens. B.Dixon (Materials Res. Lab., Defence Sci. & Technol. Organisation, Melbourne, Australia).
Prakt. Metallogr. (Germany), vol.20, no.6, p.306-9 (June 1983). In English, German.
The procedure involves using a chemical polish followed by an etch using modified Fry's reagent, an etchant commonly used to reveal deformation zones in mild steel. Macrophotography is done with oblique illumination while the specimen is submerged under alcohol. (1 ref.)

109651 Application of the four-point bending technique on single edge notched specimens to the fracture behavior of ceramics. A.Fontaine (Dept. des Materiaux, Ecole Polytech. Federale de Lausanne, Lausanne, Switzerland), D.Francois.
Rev. Int. Hautes Temp. & Refract. (France), vol.19, no.3, p.159-69 (1982). In French.
In order to better understand the conditions of validity of the fracture test on ceramics, four point bend specimens made of sintered alumina were tested under conditions of either fast or delayed fracture. Acoustic emission allowed one to detect in fast fracture tests an inition point to which a fracture toughness K_A which has a good reproducibility corresponds. The fracture toughness increases while the crack propagates until it stabilises when the damaged zone at the crack tip reaches its full development. The rate at which this plateau value, characteristic of each material, is reached, depends upon the loading rate. The delayed fracture tests were performed either at constant load or at constant displacement. In the first case, the three usual phases observed in stress corrosion cracking were observed while in the second one the plot of the logarithm of the crack velocity as a function of the logarithm of the stress intensity factor, had a single steep slope corresponding to a crack tip which propagates within a relatively large damaged zone. (7 refs.)

109652 Critical evaluation of double torsion tests. M.Boussuge, E.Inghels, J.Lamon (Ecole Nat. Superieure des Mines de Paris, Evry, France).
Rev. Int. Hautes Temp. & Refract. (France), vol.19, no.3, p.185-206 (1982). In French.
An elastic analysis of the double torsion specimen is proposed. It takes into account the deformations of the whole specimen and not just the torsion beams. The results are compared with the stresses and the deflections measured on metallic and PMMA specimens. The compliances predicted using this analysis are in good agreement with the measurements performed on reaction bonded silicon nitride. (7 refs.)

109653 Development of a high temperature double torsion apparatus. A.Mamoun, G.Fantozzi, G.Orange (Groupe d'Etudes de Metallurgie Phys. et de Phys. des Materiaux, INSA, Villeurbanne, France).
Rev. Int. Hautes Temp. & Refract. (France), vol.19, no.3, p.207-23 (1982). In French.
The strength degradation with time of ceramics is due to the onset of slow crack growth. The degradation can limit the utilization of these materials as structural components. So, it is fundamental to characterise the mechanisms reponsible for this degradation to assure reliability of components in service and also to optimize the microstructure in order to produce high performance materials. The authors have designed a double torsion apparatus working up to 1500°C, in different atmospheres, to determine the relationship between the crack velocity V and the stress intensity factor K_1. This apparatus has been tested aluminas (Al 23 and AF 997) at room temperature, in air and water, and at 600°C. The influence of specimen thickness on the diagram (K_1, V) has been studied. Tests under higher temperatures and under various atmospheres conditions (air and inert gas atmosphere) are presently in progress. (58 refs.)

109654 Investigation by Vickers indentation of the fracture toughness of experimental batches of sintered polycrystalline SiC. R.Moussa, J.L.Chermant, F.Osterstock (Lab. de Cristallographie, Univ. Caen, Caen, France).
Rev. Int. Hautes Temp. & Refract. (France), vol.19, no.3, p.225-38 (1982). In French.
The critical stress intensity factor has been determined for an experimental batch of SiC, using the controlled flaw method and the Vickers indentation radial crack size method. The difference between the values for K_C obtained according to the used methods, are linked to the existence of a process zone. The nature and the size of this zone of microcracking depends on the microstructure of the material. (23 refs.)

109655 Study of the thermomechanical behaviour of ceramics by acoustic emission. N.Ouanezar, D.Rouby, G.Fantozzi (Groupe d'Etudes de Metallurgie Phys. et de Phys. des Materiaux, INSA, Villeurbanne, France).
Rev. Int. Hautes Temp. & Refract. (France), vol.19, no.3, p.239-53 (1982). In French.
Notch opening tests were carried out on CT 10 specimens of zirconia (ZrO_2 PSZ-Mg). The acoustic emission originated in slow crack growth. Examples of detected signals are shown: the direct signal emitted from the source mechanism is pulse shaped; the signals following results from the wave's reflections and mode's conversion inside the specimen. Temporal analysis of the signals give access to the localization of the acoustic emission sources in the specimen. The results of the localization are shown and discussed in the light of the slow crack growth processes in the materials. A study of thermal shock by acoustic emission is presented. The thermal shock set-up is described. The evolution of the acoustic emission as a function of the thermal temperature is put forward. The advantage of the acoustic emission technique in the study of behaviour of ceramic materials is discussed. (13 refs.)

109656 Investigation of the link between the rate and magnitude of plastic deformation and acoustic emission energy. V.S.Ivanova, N.S.Kuznetsov.
Russ. Metall. (GB), no.1, p.163-7 (1982). Translation of: *Izv. Akad. Nauk. SSSR Met.*, no.1, p.191-5 (1982).
In the present investigation, based on concepts of the dislocation nature of acoustic emission signals and on the assumption that the energy of acoustic emission, caused by moving dislocations (or their groups) in the course of deformation, is proportional to their kinetic energy, the relationship between the acoustic emission energy and the parameters, which define the conditions and stages of deformation, is studied. (11 refs.)

109657 A new technique of hydrogen charging of a TEM specimen. H.Matsui, O.Kubota, N.Yoshikawa, M.Koiwa (Res. Inst. for Iron, Steel & Other Metals, Tohoku Univ., Sendai, Japan).
Scr. Metall. (USA), vol.17, no.7, p.923-5 (July 1983).
Two types of very simple and reliable techniques for the hydrogen doping of Va metals (Nb, V, Ta) are reported. (5 refs.)

109658 Skoda concern's present methods of non-destructive material testing. M.Hampejs.
Skoda Rev. (Czechoslovakia), no.1, p.37-45 (1983).
Discusses the development of flaw detection methods by Skoda and its programme directed towards improvements. (no refs.)

109659 Determination of ultimate strength in bending for glass tubes by a radial compression method. E.A.Abramyan, D.L.Orlov, S.V.Golenkov (State Sci. Res. Inst. of Glass, Moscow, USSR).
Strength Mater. (USA), vol.14, no.7, p.992-5 (July 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.7, p.116-18 (July 1982).
In studying the effect of residual stresses in glass tubes on their strength properties the radial compression method proposed is preferred over other well-known methods, and a promising direction for improving the mechanical strength of glass tubes is to do away with the secondary anneal in a furnace and to create residual stresses at the inner surface during tube-drawing in the pit of the VTD machine by intensifying inner surface cooling. (6 refs.)

109660 Use of strain-measurement methods for recording acoustic emission. Yu.S.Vorob'ev, A.V.Kolodyazhnyi, V.V.Voronin (Inst. of Problems of Machine Building, Acad. of Sci., Khar'kov, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.8, p.1144-7 (Aug. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.8, p.126-8 (Aug. 1982).
The proposed method for recording acoustic emission was investigated with the use of a type KTD-2A silicon semiconductor strain gauge in pure bending of a 400×10×10 mm U8 steel beam with a triangular cut in the center. (2 refs.)

109661 Experimental equipment and method for examining damage cumulation in softening polymer composite materials. R.P.Apinis, S.L.Skalozub.
Strength Mater. (USA), vol.14, no.8, p.1151-4 (Aug. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.8, p.131-4 (Aug. 1982).
Experimental equipment is described for examining the dynamic modulus of elasticity and the mechanical loss angle of rigid polymer materials during fatigue failure. The equipment operates in resonance conditions. The resonance frequency is determined by the dynamic modulus of elasticity, dimensions, and configuration of the specimen. The load cycle is sinusoidal with a stress ratio of $r = -1$. In the equipment, the specimen can be cooled to suppress heating due to vibrations. (5 refs.)

109662 Equipment for fatique testing large numbers of specimens. A.d.Puzankov, Yu.I.Ivanov, A.A.Glotov, V.A.Konovalov (Moscow Inst. of Railroad Transport Engrs., Moscow, USSR).
Strength Mater. (USA), vol.14, no.8, p.1155-6 (Aug. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.8, p.135-6 (Aug. 1982).
The equipment consists of a vibration table, a static frequency converter, and a measuring system. The equipment, in which forces up to 12.10^4 N can be generated at an oscillation frequency of 18-20 Hz, can be used to test simultaneously six flat cantilevered specimens in cyclic bending and to produce a symmetric or asymmetric cycle of stress variants in each specimen. Power is supplied to the equipment from a 380 V three-phase mains with industrial frequency. The required power does not exceed 30 kW, and the equipment weighs 2500 kg. (no refs.)

109663 Stress-strain curves for high-temperature monotonic loading. N.A.Makhutov, V.N.Merkulov (Moscow Aviation Engng. Inst., Moscow, USSR).
Strength Mater. (USA), vol.14, no.10, p.1299-303 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.12-15 (Oct. 1982). [received: Sept. 1983]
It is concluded that in analyzing fracture under monotonic loading at high temperature, when elastoplastic strain is accompanied by creep strain and long-time static damages are accumulated, strain approaches can be justifiably used. Such approaches consider the degree of development of inelastic strain, the change in the resistance to deformation, long-time ductility characteristics, and the three-dimensional character of the stress state in crack zones. These factors are fundamental in the stage of stable crack growth and determine the limiting loads for the given loading conditions (with respect to rates and temperatures); the stress-strain diagrams obtained in this case permit evaluation of the limiting loads and critical flow size with allowance for flaw growth. (12 refs.)

109664 Determination of life under two-frequency loading. II. Proposed method. V.I.Trufyakov, V.S.Koval'chuk (E.O. Paton Inst. of Electronic Welding, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.10, p.1303-8 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.15-20 (Oct. 1982). [received: Sept. 1983]
For pt.I see ibid., vol.14, no.9, p.1165 (1982). A formula is proposed to evaluate the effect of the super-position of a high-frequency component on the fatigue life under two-frequency loading using the change in the life corresponding to low-frequency loading. (8 refs.)

109665 Study of the strain characteristics of materials and evaluation of deformation conditions in concentration zones with nonisothermal cyclic loading. A.G.Kazantsev (A.A. Blagonravov Inst. of Engng. Sci., Acad. of Sci., Ukrainian SSR).
Strength Mater. (USA), vol.14, no.10, p.1308-13 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.20-5 (Oct. 1982). [received: Sept. 1983]
Analysis of the results obtained shows that in isothermal loading at 150 and 650°C stabilization of the stress-strain curve leads to a situation whereby the loading on the hole contour and at the notch root approaches severe

(ϵ=const) conditions after the third half-cycle. In nonisothermal loading, there is no such complete stabilization after the same number of half-cycles. In this case, the strains are greater than those seen under isothermal loading at 150°C and less than those seen under isothermal loading at 650°C. This difference reaches 30-40%, which must be taken into account in evaluating low-cycle strength. When temperature changes within a broader range, as well as in the case of materials with a more pronounced dependence of strain characteristics on temperature, this difference may be even more substantial. (6 refs.)

109666 Prediction of endurance on the basis of characteristic loading parameters. I.G.Zavalich, L.A.Shefer (Chelyabinsk Polytech. Inst., Chelyabinsk, USSR).
Strength Mater. (USA), vol.14, no.10, p.1314-20 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.25-30 (Oct. 1982). [received: Sept. 1983]
A method is proposed which permits the conversion of fatigue characteristics from one process to another without schematization, and use of the fatigue damage summation hypotheses. The method is based on the equivalence of random and programmed loading processes. Tests were conducted in cantilever bending on flat specimens of materials differing in both chemical composition and strength properties (aluminum alloy AMg6, heat-resistant steel D152, glass-fiber-reinforced plastic PPN), making it possible to determine $\sigma_{\min}$ as a quantity independent of the test material. (7 refs.)

109667 Experimental determination of the stress intensity factor in bending for a cylindrical single-edge-cracked specimen. A.V.Prokopenko (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.10, p.1327-30 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.37-40 (Oct. 1982). [received: Sept. 1983]
A method is proposed for determining the SIF for surface single-edged fatigue cracks in smooth cylindrical specimens under bending load. This makes it possible to find the SIF for smaller cracks than can be determined by using the former method, which involves measurement of elastic yielding. For a relatively large crack length the proposed method produces results which are in good agreement with those obtained by the method of measurement of the elastic yielding of crack-bearing specimens. (13 refs.)

109668 One experimental method of determining the maximum stresses in splitting. V.I.Romanchenko, G.V.Stepanov (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.10, p.1345-7 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.53-5 (Oct. 1982). [received: Sept. 1983]
Investigates the possibility of directly finding the maximum tangential stresses σ_* in the plane of splitting, based on recording the profile of the load wave by a pressure sensor. (7 refs.)

109669 An apparatus for determining the deformability of a material in a complex strain state with neutron irradiation from the Neitron 9 unit. G.S.Pisarenko, A.P.Voloshchenko, M.M.Aleksyuk, V.K.Lukashev, V.I.Prokopenko, Yu.A.Kuzema, B.V.Samsonov, A.Ya.Rogozyanov, V.K.Gorbatov (Inst. of Strength Problems, Acad. of Sci, Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.10, p.1407-13 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.104-9 (Oct. 1982). [received: Sept. 1983]
The Neitron 9 equipment was developed for examining the deformation of materials in combined states of strain under neutron irradiation. The apparatus consists of a loading device placed in a reactor channel and control systems mounted in five instrument racks. Rack 2 contains the control system for the electric heater, while rack 3 contains the system for measuring and recording the data from the transducers, and rack 4 contains the system providing automatic control of the strain rate. The design involves locating the loading device within a channel at the minimum distance from the core. This reduces the length of the loading ties and thus minimizes the error due to deformation of these. The specimen is loaded with an axial tensile force and torque. Both loads are applied with constant strain rates and with a constant ratio between them. (8 refs.)

109670 Equipment of type DSO for fatigue testing in repeated impact and harmonic loading with various stress ratios. V.A.Degtyarev (Inst. of Strength Problems, Acad. of Sci., Kiev, Ukrainian SSR).
Strength Mater. (USA), vol.14, no.10, p.1413-16 (Oct. 1982). Translation of: *Probl. Prochn. (USSR)*, vol.14, no.10, p.110-13 (Oct. 1982). [received: Sept. 1983]
The equipment was constructed to examine the effect of the stress ratio of the load cycle of impact loading on the fatigue of materials and welded joints in flat bending. The distinguishing features of equipment DSO-1 are the static loading mechanism and the unit for clamping the specimen. The clamping unit consists of the support for the cantilever clamping of the specimen. The support is designed in such a manner that the line of load application passes inside the contour of the surface by which the support is fixed to the body of the impact tester. (5 refs.)

109671 Feasibility of coating inspection by gamma-albedo method. O.I.Nedavnii (Sci. Res. Inst. of Electronic Introscopy, Tomsk, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.10, p.755-9 (Oct. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.10, p.3-8 (Oct. 1982). [received: Sept. 1983]
The feasibility of inspecting coatings of heavy materials on substrates of materials with low atomic number by utilizing the backscattering of low-energy gamma radiation is demonstrated on the lead-aluminum combination. The analysis is based on the physical model of an absorber-scatterer system. The effect of fluctuations of the substrate thickness on the accuracy of thickness measurements is evaluated. (9 refs.)

109672 A standard photometric method of determining beam sizes of defects. V.M.Zuev, V.I.Ivanov (Central Sci.-Res. Inst. of Technol. & Mech. Engng., Moscow, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.10, p.764-70 (Oct. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.10, p.14-21 (Oct. 1982). [received: Sept. 1983]
A standard photometric method is described for determining the sizes of defects in the beam direction, with allowance for the detailed working conditions. The method allows one to estimate the beam dimensions of the following types of defects in welded joints: gas pores, unwelded spots, slag inclusions, hair cracks, and runs. (8 refs.)

109673 Experimental study of flaw detection by means of laser radiation. R.E.Krzhizhanovskii, N.M.Filippov, A.D.Rumyantsev.
Sov. J. Nondestr. Test. (USA), vol.18, no.10, p.773-5 (Oct. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.10, p.26-7 (Oct. 1982). [received: Sept. 1983]
The detection of flaws by means of laser generated acoustic pulses is discussed. The influence of the relative disposition of a flaw, the probe, and the point of injection of the laser radiation, on the receiving conditions for the useful signal is examined. It is shown that an inspection can be performed in two stages with the same arrangement: a region is first searched for the presence of flaws and then they are studied in detail. (3 refs.)

109674 Nondestructive inspection of the quality of materials and components using multitransducer eddy-current devices. B.V.Korneev, A.P.Alekseev (Kuibyshev Inst. of Electrotech. Communications, Kuibyshev, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.10, p.778-86 (Oct. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.10, p.30-9 (Oct. 1982). [received: Sept. 1983]
Reports on eddy-current devices for nondestructive inspection with several transducers are systematized. Advantages of these devices in comparison with single-transducer devices are shown, and the direction of further improvement of the former is outlined. (59 refs.)

109675 Topography of electromagnetic field at ferromagnet-air interface generated by volume shear waves. R.S.Il'yasov, V.A.Komarov (Inst. of Metal Phys., Acad. of Sci., USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.10, p.796-800 (Oct. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.10, p.49-54 (Oct. 1982). [received: Sept. 1983]
Measurements were made of electromagnetic field distributions over the surface of an electrically conducting ferromagnetic material (Armco iron) polarized by a tangential magnetic field during electromagnetoacoustic two-fold conversion. It was found that volume shear waves are the ones most intensely excited when laid-on transducers are used. Here it is demonstrated that for measuring the electromagnetoacoustic field generated by such vibrations, it is most expedient to use search coils which record the normal component of the electromagnetic field. (6 refs.)

109676 Interference resistance of tests on ferromagnetic products by Barkhausen-noise parameters. V.A.Shakhnin, N.S.Kazakov, A.S.Petyaev (Omsk Polytech. Inst., Omsk, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.10, p.801-4 (Oct. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.10, p.54-7 (Oct. 1982). [received: Sept. 1983]
The results of an experimental investigation into the effects that the conditions of magnetization and the magnetic history of the testpiece have on the Barkhausen-noise EMF are reported. The authors show that magnetizing the testpiece by fields at two frequencies increases the reliability of the test results. (4 refs.)

109677 Measurement of the acoustical properties of plastics. I.N.Ermolov, V.I.Timofeev (Central Sci. Res. Inst. of Technol. & Mech. Engng., Moscow, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.10, p.806-9 (Oct. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.10, p.60-3 (Oct. 1982). [received: Sept. 1983]
A study of the acoustical properties of plastics is reported. The existing data on the attenuation of longitudinal ultrasonic waves in organic glass (Plexiglas type), polystyrene, and compound K-153 are subjected to a critical analysis. It is established that the published data on the ultrasonic velocities are in good agreement with the data obtained, but the values of the attenuation coefficients are too high. The attenuation coefficient is determined by comparing the amplitudes of bottom signals measured in two or more samples of different heights. It is shown that the multiple-reflection method of measuring the attenuation yields results that are too high. Practical recommendations are given for measuring the attenuation coefficient in plastics. (2 refs.)

109678 Acoustical characteristics of some polymers used as test specimens. V.A.Tokarev, E.I.Seregin, V.P.Glukhovskii (Sci.-Res. Inst. of Building Structures, Kiev, Ukrainian SSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.10, p.812-15 (Oct. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.10, p.67-70 (Oct. 1982). [received: Sept. 1983]
The acoustical characteristics of polymer materials (Plexiglas, ebonite, and Teflon) are investigated. It is shown that Plexiglas, in comparison with ebonite and Teflon, has the lowest temperature coefficient of the velocity of ultrasound. In the course of natural aging, Plexiglass retains a high stability of the velocity of ultrasound for a long period of time, making it the preferred material for the fabrication of standard specimens. (7 refs.)

109679 Effect of heat treatment conditions on the form of the scattered pulse and the mean level of structural noise for steels with a homogeneous structure. V.L.Busov (Sci.-Res. & Design Technol. Engng. Inst., Kramatosk, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.10, p.815-24 (Oct. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.10, p.70-81 (Oct. 1982). [received: Sept. 1983]
The method of small interferences was used to determine the form of the envelope of the echo signal and the mean level of structural noise in the backscattering of ultrasonic waves on specimens with a homogeneous structure. The effect of the dimensions of random inhomogeneities of the medium on the mean level of structural noise for annealed and quenched specimens was explained on the basis of the results. (15 refs.)

109680 Acoustic pulses excited by impacts on objects—their analytical representation and spectra. Yu.V.Lange, E.G.Ustinov (Sci.-Res. Inst. of Introscopy, Moscow, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.10, p.825-30 (Oct. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.10, p.81-7 (Oct. 1982). [received: Sept. 1983]
The problems of impact-excited elastic vibrations for the inspection of objects by the free-vibration method are discussed. A formula is proposed to approximate these pulses and it is compared with experimental data. The spectra of impact pulses having various degrees of asymmetry are calculated. (11 refs.)

109681 Characteristics of acoustic measurements in highly absorptive media. M.B.Gitis, A.A.Shenker (All-Union Sci.-Res. Inst. for Dev. of Nondestructive Methods & Means of Materials Quality Control, Kishinev, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.10, p.831-7 (Oct. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.10, p.87-94 (Oct. 1982). [received: Sept. 1983]
The distortions of elastic pulse shapes in highly absorptive media have been investigated. Asymptotic expressions have been derived that describe the shape of a rectangular wave packet with a high sinusoidal pulse-modulated frequency which are functions of parameters for the medium and the path that is traversed. It is shown that in certain situations the change of shape for signals during their propagation can substantially distort measurements made on the velocity and the coefficient of sound absorption by the usual methods. A modification of the procedure is proposed that makes it possible by means of low-frequency measurements to determine all the internal characteristics of a medium having a single relaxation time. (10 refs.)

109682 Nondestructive inspection by the method of magnetic leakage fields. Theoretical and experimental foundations of the detection of surface cracks of finite and infinite depth. F.Forster (Dr. F. Forster Inst., Reutlingen, Germany).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.841-58 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.3-25 (Nov. 1982). [received: Sept. 1983]
A historical review is given of the development of the method of magnetic leakage fields for nondestructive inspection. The leakage field of surface cracks of infinite and finite depth is examined for the linear case. Some calculation methods are presented which make it possible to express a number of regularities of magnetic leakage fields in simple elementary formulas. (13 refs.)

109683 Algorithm for determining the dimensions of flaws in the theory of eddy-current flaw detection by superposed transducers. Yu.K.Fedosenko (Sci. Res. Inst. of Introscopy, Moscow, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.859-63 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.25-30 (Nov. 1982). [received: Sept. 1983]
On the basis of previously obtained formulas expressing the correlation of the insertion voltage with the dimensions of a flaw and of the transducer winding, the author investigates algorithms for determining parameters of inhomogeneity. The problem reduces to the numerical analysis of a system of five nonlinear equations. The author examines methods of forming such a system and ways of solving it. He analyzes possible special cases. (5 refs.)

109684 Inspection of case hardening by method of higher harmonics. E.G.Revkov, V.V.Klyuev, A.D.Pokrovskii, Yu.P.Khvalebnov (Moscow Inst. of Power Engng., Moscow, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.864-70 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.30-8 (Nov. 1982). [received: Sept. 1983]
A method has been developed for evaluating the signals from a feedthrough transducer during inspection of case hardening by the method of higher harmonics. Modes of quality control are selected on this basis. Also, the change in electric field intensity necessary for optimal inspection of objects with variable length is estimated. (10 refs.)

109685 Magnetic testing of the mechanical properties of tube material using ferropickup coercimeters. V.I.Roitman, O.S.Konovalov, A.S.Golovko, R.M.Brusentsova, N.B.Batrak, M.V.Teneta (50th-Anniversary-of-the-Great-October-Socialist-Revolution Nikopol'skii Yuzhnotrubnyi Factory, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.871-7 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.39-45 (Nov. 1982). [received: Sept. 1983]
An improved method for the magnetic monitoring of the mechanical properties of steel tubes is described, based on investigations of the behaviour of the demagnetizing current as a function of the diameter and thickness of the tube walls, which considerably reduces the time required to carry out such monitoring under industrial conditions. (8 refs.)

109686 Extension of the region of tuning out of the effect of changes in the gap between the transducer and the article under test in the pulsed magnetic method of testing. M.A.Mel'gui, V.F.Matyuk (Inst. of Appl. Phys., Acad. of Sci., Belorussia SSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.877-80 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.46-9 (Nov. 1982). [received: Sept. 1983]
An approximation of the distribution of the gradient of the normal component of the residual field of a locally magnetized article by a power function is proposed. The region in which the effect of changes in the gap between the transducer and the article being monitored is tuned out is compared when measuring the sum of the gradients of the residual field on two sides of the article and when measuring their geometric mean. (3 refs.)

109687 A scanning induction transducer for the inspection of flat surfaces. A.I.Pashagin, V.E.Shcherbinin, B.A.Filippov (Inst. of Metals Phys., Acad. of Sci., USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.881-5 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.50-5 (Nov. 1982). [received: Sept. 1983]
The authors describe a simple induction transducer with a stationary coil and a core rotating inside the coil eccentrically with respect to the coil axis. The transducer is used for the inspection of joints in pipes welded by arc welding. The detectability of defects with this transducer in magnetic inspection, in relation to the strength of the applied field and the defect size, is examined. The characteristics of the transducer are described in relation to the parameters of the cores. (4 refs.)

109688 Automatic devices for the electromagnetic inspection of the thickness of the coating on small components. A.S.Kanaev (Inst. of Phys., Acad. of Sci., Latvian SSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.886-90 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.55-9 (Nov. 1982). [received: Sept. 1983]
Methods and devices for the detection of the presence and thickness of coatings on components are examined. Special attention is given to the special features of identifying multilayer components produced by powder metallurgy methods. The technical characteristics of automatic devices for electromagnetic inspection are presented. (3 refs.)

109689 Estimation of extra useful life of objects by monitoring acoustic emission. V.I.Ivanov (Central Sci.-Res. Inst. of Technol. & Machine Construction, Moscow, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.891-4 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.60-4 (Nov. 1982). [received: Sept. 1983]
Based on a probability study of dependable operation for equipment, an expression has been obtained for determining its extra useful life. It is shown that by employing a nondestructive monitoring method, specifically the acoustic-emission method, it is possible to determine the guaranteed extra useful life. (4 refs.)

109690 Absolute sensitivity of series-produced ultrasonic defectoscopes. I.N.Ermolov, M.S.Naumov (Central Sci.-Res. Inst. of Technol. & Machine Construction, Moscow, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.895-7 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.64-8 (Nov. 1982). [received: Sept. 1983]
The absolute sensitivity of several commercial defectoscopes is calculated from technical data and determined from actual measurements. It is demonstrated that this characteristic can serve as a basis for comparing the capabilities of various instruments with regard to flaw detection in fine-grain materials. (2 refs.)

109691 Effect of delay in contact layers on accuracy of measurement of ultrasound propagation time. I.I.Vainshtok, V.S.Lerner (Moscow Highway Inst., Moscow, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.898-902 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.68-72 (Nov. 1982). [received: Sept. 1983]
The delay of ultrasound in contact layers of lubricant is examined in the case of obliquely incident waves. The dependence of the time delay on the acoustic properties of the materials forming the contact layer is analyzed, and a scheme is proposed for measuring the propagation time with compensation of delays. (7 refs.)

109692 Standardizing the terminology of the acoustic-emission method. Yu.B.Drobot, V.I.Ivanov, E.G.Smirnov (Central Sci.-Res. Inst. of Technol. & Mech. Engng., Moscow, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.902-5 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.72-6 (Nov. 1982). [received: Sept. 1983]
Technical standardization documentation published in various countries on the terminology used in connection with acoustic emission is briefly surveyed. The terms relating to acoustic emission are given, along with their definitions and notation in accordance with the Soviet All-Union State Standard (GOST) 25.002-80. (17 refs.)

109693 Detection of a corner reflector with insonification at angles greater than 45°. V.S.Goncharov.
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.906-9 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.76-9 (Nov. 1982). [received: Sept. 1983]
It is shown that the acoustic path for a corner reflector can be calculated by the method of images, using a simple expression. The expression takes into account the 'focusing' action of the plane when shear waves are incident on it at angles close to the critical, as well as the attenuation of the field upon reflection from a plane reflector having small dimensions in the plane of wave incidence. Since the calculated values of $A\gamma/A\gamma=45°$ have been confirmed experimentally, the derived expression can be used for flaw detection. (5 refs.)

109694 Evaluation of the information content of the characteristics of radiation scattered by the surface of geometrical bodies. E.G.Golikov, Yu.A.Kovyazin, V.S.Kortov (S.M. Kirov Ural Polytech. Inst., USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11, p.915-20 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.86-92 (Nov. 1982). [received: Sept. 1983]
The results are presented of experimental investigations into the differential characteristics of radiation scattered from objects of various geometrical form to evaluate the possibilities of the radiation inspection of the effective surface area on the basis of the energy albedo of bremsstrahlung of electron accelerators. (8 refs.)

109695 Increasing the information content of radiographic methods of inspection of welded joints. V.M.Zuev, V.I.Ivanov (Central Sci.-Res. Inst. of Engng., Moscow, USSR).
Sov. J. Nondestr. Test. (USA), vol.18, no.11 (Nov. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.11, p.92-6 921-4 (Nov. 1982). [received: Sept. 1983]
Problems of increasing the information content of the radiographic inspection of welded joints by using improved methods of estimating the beam dimensions of defects are examined. The accuracy and information content of the standard-photometric method of determining the dimensions of defects in the direction of radiation are analyzed. (3 refs.)

109696 Measurement of mutual impedance in eddy current testing coils. I.Uetake, R.Kuwae, H.Ito.
Trans. Natl. Res. Inst. Met. (Japan), vol.25, no.2, p.87-96 (June 1983).
Describes the results of mutual impedance measurements of self-comparison type encircling coils for eddy current testing. The measurements were performed on coils with austenitic stainless steel (SUS304) and carbon steel (S25C) bars, variating the dimensions of the coil, specimen and defect, coil-to-coil spacing and DC magnetizing strength. It was shown that the locus of mutual impedance could be explained by the law of similarity and was influenced by DC magnetizing strength. (9 refs.)

109697 Stress analysis of a rotating cylinder experiment to determine crack growth in thick section steel. K.Reading, A.M.Clayton.
Report ND-R-892(R), UKAEA, Risley, Lancs., England (June 1983), 25 pp.
Available from HMSO, London, England.
An experiment has been proposed to validate fracture assessment methods for thick walled components under 'upper shelf' conditions, using a thick walled cylinder. The cylinder is rotated to produce primary stresses. To produce secondary stresses it is heated and then quenched on the inside face. The authors compare the stress system to that of a pressure vessel and specify suitable dimensions of the cylinder to obtain 2 mm of slow ductile tearing of a full length longitudinal starter crack on the inside wall, before net section yield occurs. The results from a specially developed computer program to analyse the cylinder fracture behaviour under thermal shock are described. It is shown that the rotating cylinder adequately reproduces the essential features of fracture in a large pressure vessel. (11 refs.)

81.90 OTHER TOPICS IN MATERIALS SCIENCE

109698 New method for solid-state bonding between ceramics and metals. K.Suganuma, T.Okamoto, M.Shimada, M.Koizumi (Inst. of Sci. & Industrial Res., Osaka Univ., Ibaraki, Osaka, Japan).
J. Am. Ceram. Soc. (USA), vol.66, no.7, p.C117-18 (July 1983).
A new method for solid-state bonding between ceramics and metals was developed. An interlayer, which is a composite of the materials to be bonded, is used. The technique can be applied to materials which cannot be bonded by conventional diffusion-bonding methods because of thermal-expansion mismatches. It is expected that the bonded materials will have excellent thermal shock resistance. (4 refs.)

109699 Drying of materials in magnetic high-frequency field. Yu.P.Yulenets, A.K.Arkhipov, A.V.Zhogin (Lensovet Leningrad Technol. Inst., Leningrad, USSR).
J. Eng. Phys. (USA), vol.44, no.1, p.73-5 (Jan. 1983). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.44, no.1, p.88-91 (Jan. 1983). [received: Sept. 1983]
A theoretical analysis is made of energy relations which determine the efficiency of drying granular materials in a magnetic high-frequency field. (5 refs.)

109700 Comparison of the adhesion and cohesion of triblock and random copolymers of styrene and butadiene. G.R.Hamed (Inst. of Polymer Sci., Univ. of Akron, Akron, OH, USA).
J. Adhes. (GB), vol.16, no.1, p.31-9 (1983).
A substantially greater detachment energy is required to strip a polyethylene terephthalate (Mylar) film from a styrene-butadiene-styrene (SBS) triblock copolymer compared to that for peeling from a random styrene-butadiene (SBR) copolymer. It is proposed that this difference in peel strength (between the SBS and SBR) is a consequence of the much higher dissipative capacity of the former elastomer. Another manifestation of this is the higher cohesive tear strength of the SBS compared to the SBR. Extents of energy dissipation within each elastomer during detachment of the Mylar adherend are consistent with the hypothesis that the average maximum stress experience before detachment is some similar fraction of each elastomer's tensile strength. (11 refs.)

109701 Scientific goals of the D1-mission (Spacelab). P.R.Sahm, R.Jansen (Aachen Inst. of Technol., Aachen, Germany).
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.115-17
Tha aim of the D1-mission is to utilise microgravity environment in space for basic research in the field of materials science (MS) and the life sciences (LS). The various disciplines involved in this mission including important mission parameters are shown. Presently about 70 experiments have been preselected for the D1-mission. The ratio between MS and LS experiments is almost 2:1. In addition, two more technologically oriented experiments dealing with navigation will be on board. The lowest common denominator of most of the involved experiments still remains their microgravity relevance and resulting effects. The multiplicity of experiments has led to numerous contacts between scientists of different disciplines, and highly valuable scientific interactions have taken place. for example, crystal growers and fluid dynamicists are effectively interacting on crystal growth theory, and new knowledge has resulted. Also, first connections are being established presently between the life sciences and fluid dynamics. (no refs.)

82.00 PHYSICAL CHEMISTRY

82.20 CHEMICAL KINETICS

109702 The influence of catalyst dilution by inert particles on the effectivity of a catalytical process in a fluidized bed. A.A.Augenblick, V.A.Kernerman, G.N.Abayev, M.G.Slin'ko (Karpov Phys. Chem.-Inst., Moscow, USSR), Yu.A.Sergeev.
Chem. Eng. Sci. (GB), vol.38, no.8, p.1217-22 (1983).
The method of the increasing a selectivity of catalytic processes in fluidized bed reactor by decreasing local chemical reaction rates together with increasing a reactive volume is discussed. Based on the two-phase model of a fluidized bed it is shown that the dilution of a catalyst by inert particles leads to an increasing of effective interphase exchange coefficients and a decreasing of effective axial mixing coefficients. Restrictions to applications of the method connected with local features of a bed structure are discussed. (22 refs.)

109703 The hysteresis of steady states in a gradientless liquid-phase reaction system. A.H.Heemskerk, J.M.H.Fortuin (Lab. voor Chem. Technol., Amsterdam, Netherlands).
Chem. Eng. Sci. (GB), vol.38, no.8, p.1261-9 (1983).
The dynamic behaviour of a reaction system in a continuous-flow stirred tank reactor is described by a model comprising the unsteady mass and heat balances and the kinetics of the reaction system concerned. This model predicts that under certain conditions a hysteresis effect will occur, which manifests itself when the steady-state temperature of the reaction system is plotted against the reference temperature. A number of experiments concerning the hysteresis effect are reported. The measurements were carried out with a well-mixed and well-insulated 236 ml reaction vessel provided with a stirrer and baffles. The reactor was filled completely with an aqueous reaction system for the acid-catalyzed hydration of methyloxiran. (11 refs.)

109704 Thermal behaviour of agitated gas-liquid reactors with a vaporizing solvent. Air oxidation of hydrocarbons. K.R.Westerterp, P.R.J.J.Crombeen (Dept. of Chem. Engng., Twente Univ. of Technol., Enschede, Netherlands).
Chem. Eng. Sci. (GB), vol.38, no.8, p.1331-40 (1983).
Many highly exothermic gas-liquid reactions are carried out with a vaporizing solvent, which after condensation is returned to the reactor. In this way the liberated reaction heat for a large part is absorbed by the cooling water flowing through the condenser. In order to determine the influence of this evaporation on the behaviour of an agitated gas-liquid tank reactor a model second order reaction was studied. The temperature dependence of the enhancement factor is strongly affected by the solvent evaporation. The influence of several design and operation parameters such as liquid residence time, dilution of reactant with solvent, air excess in the gas phase and reactor pressure on the conversion and the reactor pressure is demonstrated. (35 refs.)

109705 Falsification of kinetic parameters by incorrect treatment of recirculation reactor data. S.Wedel, J.Villadsen (Dept. of Chem. Engng., Tech. High School, Lyngby, Denmark).
Chem. Eng. Sci. (GB), vol.38, no.8, p.1346-9 (1983).
The authors propose the falsification ratio C as a new criterion to estimate the error that arises from treating the recycle reactor as CSTR. (6 refs.)

109706 Falsification of kinetic parameters by incorrect treatment of recirculation reactor data. R.Broucek (Univ. Erlangen-Nurnberg, Erlangen, Germany).
Chem. Eng. Sci. (GB), vol.38, no.8, p.1349-50 (1983).
S. Wedel and J. Villadsen (see ibid., vol.38, p.1346-9 1983) propose the falsification ratio ρ as a new criterion to estimate the error that arises from treating the recycle reactor as CSTR. The missing information of an upper limit of ρ which can still be tolerated complicates the practical use of the new criterion. The present author shows that this upper limit could be derived from the well-known demand for a gradient-free catalyst bed concerning concentration and temperature. (2 refs.)

109707 The enumeration of reaction pathways using Burnside's lemma. T.J.McLarnan (Dept. of Chem., Univ. of Chicago, Chicago, IL, USA).
Theor. Chim. Acta (Germany), vol.63, no.3, p.195-207 (1983).
Formulas are given for the number and statistical weights of reaction pathways and from one molecular conformation to another via a given transition state. Arbitrary mechanistic assumptions can be incorporated into this enumeration. These formulas arise as straightforward generalizations of an expression for the number of double cosets in any group, which can be proven in one line using Burnside's lemma. (26 refs.)

109708 Reactions in glass melt systems. G.H.Frischat, M.Braedt, W.Beier (Inst. fur Nichtmetallische Werkstoffe, Tech. Univ. Clausthal, Clausthal, Germany).
Proceedings of the 4th European Symposium on Materials Sciences under Microgravity (ESA SP-191), Madrid, Spain, 5-8 April 1983 (Paris, France: ESA 1983), p.161-5
The μg research project 'Reaction Kinetics in Glass Melts' includes the following subtopics: interdiffusion between glass melts of different compositions, corrosion of silica glass by melts, and self diffusion in glass melts. During the past five years three TEXUS rocket experiments have been undertaken and an experiment is in preparation for the FSLP mission in October 1983. The author reports on the different experiments, on their μg relevancy and how they will be designed and performed. The necessary ground-based research work is also discussed. Finally a summary of the kinetic results obtained thus far for different glass melt systems and an outline on further work are given. (9 refs.)

109709 Mode specificity of unimolecular rate constants in the Henon-Heiles system. Yi Yan Bai, G.Hose, C.W.McCurdy, H.S.Taylor (Fundamenteel Onderzoek der Materie, Inst. voor Atoom-en Molecuulfysica, Amsterdam, Netherlands).
Chem. Phys. Lett. (Netherlands), vol.99, no.4, p.342-6 (12 Aug. 1983).
The tunneling widths of high-energy metastable states lying in the classical irregular region of the Henon-Heiles potential energy surface were calculated via complex analytical continuation of stabilization graphs. Mode specificity is demonstrated in that the lifetimes of normal-mode, local-bond-mode, and mode-mixed states at nearby energies differ by an order of magnitude. (21 refs.)

109710 A simple perturbational approach for the determination of favourable reaction pathways. V.Bachler (Max-Planck-Inst. fur Strahlenchem., Mulheim, Ruhr, Germany), E.A.Halevi.
Theor. Chim. Acta (Germany), vol.63, no.2, p.83-101 (1983).
A simple perturbational approach has been used to establish the symmetry conditions for energetically favourable nuclear motions on a potential energy surface. In particular, the operational rules of Orbital Correspondence Analysis in Maximum Symmetry (OCAMS) for specifying the symmetry species of the nuclear displacements, which make a symmetry forbidden pathway symmetry-allowed, have been derived. A general, symmetry-independent, procedure is then proposed for finding the energetically most favourable pathway by referring to the form of the overlap density function of non-correlating orbitals. The method is demonstrated by selecting from among the several symmetry-allowed nuclear motions on the potential energy surface for the H_2+D_2 exchange reaction, that which is energetically most favourable. (22 refs.)

109711 Search for saddle points of energy hypersurfaces using a multidimensional space of 'guiding' coordinates. I.Balint, M.I.Ban (Inst. of General & Phys. Chem., Attila Jozsef Univ., Szeged, Hungary).
Theor. Chim. Acta (Germany), vol.63, no.3, p.255-68 (1983).
For the determination of saddle points (SPs) of adiabatic potential surfaces a novel method defining a 'pseudo reaction path' (PRP) is presented. The PRP consists of two components, the one is being the function of some selected 'guiding' coordinates and the other is depending on the remaining ones. The tangent components of the PRP are parallel and antiparallel to the normals of the tangential planes of the equipotential surfaces defined by the two groups of coordinates. PRPs starting from points in an approximately chosen domain of the configurational space arrive at the SP. (46 refs.)

82.30 SPECIFIC CHEMICAL REACTIONS; REACTION MECHANISMS

109712 Association reactions of Na^+ and some implications for interstellar chemistry. D.Smith, N.G.Adams, E.Alge (Dept. of Space Res., Univ. of Birmingham, Birmingham, England), E.Herbst.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.365-8 (1 Sept. 1983).
Three-body association reactions of Na^+ with a variety of neutral gases in the presence of He as third body have been studied in a SIFT at 80K. The measured rate coefficients are utilized to estimate radiative association rate coefficients at 20K. It is shown that Na^+-neutral radiative association reactions play a role in the depletion of Na^+ in dense interstellar clouds and can produce a sufficient amount of NaOH to explain its observed tentative abundance in Sgr B2. (25 refs.)

109713 Kinetic study of the reaction of OH with CO from 250 to 1040K. A.R.Ravishankara, R.L.Thompson (Engng. Experiment Station, Georgia Inst. of Technol., Atlanta, CA, USA).
Chem. Phys. Lett. (Netherlands), vol.99, no.5-6, p.377-81 (19 Aug. 1983).
Absolute rate coefficients (k_1) for the reaction of OH with CO have been measured in the temperature range of 250-1040K. The technique of flash photolysis-resonance fluorescence was employed for these measurements. The obtained data are best fit by the expression $k_1=\exp(-30.03+1.22\times10^{-3}T)$ cm^3 $molecule^{-1}$ s^{-1}. (14 refs.)

109714 Laser-assisted chemical reactions: semiclassical approach employing Floquet and *R*-matrix theories. M.Mohan, K.F.Milfeld, R.E.Wyatt (Dept. of Chem., Univ. of Texas, Austin, TX, USA).
Chem. Phys. Lett. (Netherlands), vol.99, no.5-6, p.411-16 (19 Aug. 1983).
A general theory of laser-assisted reactions which includes multiphoton effects is presented. The scattering dynamics is determined by the quantal R-matrix formalism and the semiclassical radiation-complex interaction is described by nonperturbative Floquet theory. The theory is applied to a model collinear A+BC reaction in an IR laser field. (23 refs.)

109715 Chemiluminescence induced in the laser-promoted reaction of ethanol with oxygen. J.M.Riveros, P.C.Isolani (Inst. de Quimica, Univ. of Sao Paulo, Sao Paulo, Brazil), S.R.A.Leite.
Chem. Phys. Lett. (Netherlands), vol.99, no.5-6, p.442-4 (19 Aug. 1983).
The vibrational multiphoton excitation of ethanol in the presence of oxygen results in chemiluminescent reactions yielding CH^* and C_2^*. The rise times of the chemiluminescence become progressively slower and the intensity increases with additional O_2 pressure. At 15 Torr of O_2 the emission duration is longer than 10 μs. (14 refs.)

109716 Model compounds for protonation of benz[a]phenazine: spectroscopy of protonated 1,2- and 3,4-benzacridines. A.Mordzinski, A.Grabowska (Inst. of Phys. Chem., Polish Acad. of Sci., Warsaw, Poland).
Chem. Phys. Lett. (Netherlands), vol.99, no.5-6, p.450-5 (19 Aug. 1983).
Absorption fluorescence and MCD spectra of 1,2- and 3,4-benzacridines (1,2- and 3,4-BAc) and their conjugate acids ($BAcH^+$) are reported. Comparison with 1,2- and 3,4-$BAcH^+$ as model compounds for singly protonated benz[a]phenazine (BfH^+) support the prior hypothesis of its distortion in the S_1 state [1]. The model of distortion−folding of BfH^+ along its N-N axis−was reproduced by INDO/S calculations. (12 refs.)

109717 Rates of OH radical reactions. The reaction $OH+SO_2+N_2$. G.Paraskevopoulos, D.L.Singleton, R.S.Irwin (Div. of Chem., Nat. Res. Council of Canada, Ottawa, Canada).
Chem. Phys. Lett. (Netherlands), vol.100, no.1, p.83-7 (26 Aug. 1983).
Absolute rate constants for the reaction $OH+SO_2+N_2$ have been determined in the gas phase, at 297K, in the pressure range 50-760 Torr. OH radicals were generated by flash photolysis of N_2O/H_2 mixtures and were monitored by time-resolved resonance absorption. The second-order rate constant k_{II} was found to depend on the pressure of N_2 and may be expressed as: $k_{II}=7.4\times10^{11}/(1+237/P)$ where P is in Torr and k_{II} in cm^3 mol^{-1} s^{-1}. (20 refs.)

109718 Prediction and interpretation of collinear reactive scattering resonances by the diagonal corrected vibrational adiabatic hyperspherical model. J.Romelt (Lehrstuhl fur Theoretische Chem., Univ. Bonn, Bonn, Germany).
Chem. Phys. (Netherlands), vol.79, no.2, p.197-209 (1 Sept. 1983).
One-dimensional single-channel scattering calculations on an effective potential are used to discuss resonances in collinear reactions and to predict their energetic location almost quantitatively. The effective potential includes the vibrationally adiabatic potential and the adiabatic diagonal correction in Delves' mass-weighted polar coordinates (hyperspherical coordinates). This diagonal corrected vibrational adiabatic hyperspherical (DIVAH) model is tested for a variety of reactions ($H+H_2$, H+MuH, I+HI, $F+H_2$) and a detailed discussion of the effective potential and its physical implications is given. (46 refs.)

109719 On the theory of adiabatic electron-transfer reactions in polar solvents. A.B.Helman (Inst. of Inorganic Chem., Acad. of Sci., Novosibirsk, USSR).
Chem. Phys. (Netherlands), vol.79, no.2, p.235-44 (1 Sept. 1983).
A theory describing the rate of adiabatic electron-transfer reactions in a polar medium with an arbitrary spectrum of the dielectric losses is presented. All results are given in terms of analytical expressions via integrals over the frequency-dependent dielectric permittivity of the solvent. The present work is a generalization of the well-known work of Kramers, concerning escape over a potential barrier, for the case where the motion on the reaction coordinate is an arbitrary normal random process and it may serve as a substantiation of the transition-state method. (22 refs.)

109720 Gas-phase solvation of NO_2^- and NO_3^- by ethyl nitrate. S.Wlodek, Z.Luczynski, H.Wincel (Dept. of Radiation Chem., Inst. of Nuclear Res., Warsaw, Poland).
Int. J. Mass Spectrom. & Ion Phys. (Netherlands), vol.52, no.2-3, p.149-63 (1 Sept. 1983).
The gas-phase clustering reactions $NO_2^-.(C_2H_5ONO_2)_{n-1}+C_2H_5ONO_2=NO_2^-.(C_2H_5ONO_2)_n$ (n=1-3) $NO_3^-.(C_2H_5ONO_2)_{n-1}+C_2H_5ONO_2=NO_3^-.(C_2H_5ONO_2)_n$ (n=1 and 2) have been studied by means of a high-pressure mass spectrometer at temperatures from 200 to 380K and at total pressures of 0.5-2 torr. Under the conditions used these reactions, with the exception of $NO_2^-+C_2H_5ONO_2=NO_2^-.C_2H_5ONO_2$, achieve thermodynamic equilibrium above 1 torr. On the basis of the temperature dependence measurements of the equilibrium constants, thermodynamic data have been determined. The following $\Delta H^0_{n-1,n}$ values were obtained: $NO_2^-.(C_2H_5ONO_2)_n$; $\Delta H_{0,1}^0=-20.9$ (indirectly obtained), $\Delta H_{1,2}^0=-8.5$ and $\Delta H_{2,3}^0=-7.3$ kcal mol^{-1}; $NO_3^-.(C_2H_5ONO_2)_n$; $\Delta H_{0,1}^0=-17.2$ and $\Delta H_{1,2}^0=-7.2$ kcal mol^{-1}. Semiempirical INDO MO calculations were performed for $NO_2^-.(C_2H_5ONO_2)_{n=1,2}$ and $NO_3^-.(C_2H_5ONO_2)_{n=1,2}$ to test the structures and binding energies of these systems. The experimental observations are discussed in terms of the structure stabilities of the solvated ions. (16 refs.)

109721 Metastable doubly-charged ions of methane studied by means of a triple-sector mass spectrometer. M.Rabrenovic, A.G.Brenton, J.H.Beynon (Royal Society Res. Unit, Univ. Coll. of Swansea, Swansea, Wales).
Int. J. Mass Spectrom. & Ion Phys. (Netherlands), vol.52, no.2-3, p.175-82 (1 Sept. 1983).
A triple-sector mass spectrometer is described in which the ion beam traverses successively a magnetic sector and two electric sectors. The advantages of this arrangement in suppressing artifact peaks and in enabling fast and slow reactions of ions formed in the region between the magnetic sector and the first electric sector are described. The instrument is used to study the fragmentation of CH_4^{2+} ions of low internal energy formed by charge stripping. Whilst unstable CH_4^{2+} ions react to give CH_2^{2+} and C^{2+}, metastable CH_4^{2+} ions give the charge separation reaction leading to CH_3^+ and H^+. The lifetime of some CH_4^{2+} ions formed by charge stripping of CH_4^+ is several microseconds. (14 refs.)

109722 Mechanism of fragmentation of organic molecules during keV particle bombardment. D.W.Moon, N.Winograd (Dept. of Chem., Pennsylvania State Univ., University Park, PA, USA).
Int. J. Mass Spectrom. & Ion Phys. (Netherlands), vol.52, no.2-3, p.217-21 (1 Sept. 1983).
A simplified scheme is presented to distinguish between surface and gas-phase fragmentation of molecular ions in SIMS or FABMS experiments. The scheme is based on the measurement of the polar angle distribution of ejected

parent and daughter cluster ions and is derived from straightforward considerations of classical mechanics. Examples are given for chlorobenzene, benzene and pyridine adsorbed on to Ag(111) at 153K. (10 refs.)

109723 Thermodynamic analysis and kinetics of dissociation of SiC. S.V.Baranov, A.G.Vodop'yanov, G.K.Moiseev, G.N.Kozhevnikov (Inst. of Metall., Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1097-100 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1300-3 (Aug. 1982).
Calculations which simulate thermal decomposition of SiC at 2000-3300K and total pressure of 9.81×10^{-2} MPa in an initial atmosphere of He and Co were performed on an ES-1040 computer based on a program which executes an algorithm for minimisation of the total potentials of the system. It was found that free carbon is formed in the condensed phase under ~2800K, while liquid silicon is also formed at 2800-3100K. Monoatomic silicon is the basic gaseous product of dissociation in an initial atmosphere of He, while silicon monoxide is the basic product in an initial atmosphere of CO. Dissociation of SiC at the same temperatures is more complete in CO than in the inert gas. The results of the computer simulation were experimentally confirmed: it was found that dissociation of SiC is more complete in CO than in the inert gas; carbon is found in samples of SiC heated to 2270K, while metallic silicon is found at 2770K. A correlation between the rate constant of dissociation of SiC and the temperature was obtained for the 2270-2670K interval in an atmosphere of CO. (2 refs.)

109724 Formation of tungsten carbides on reaction of tungsten trioxide with carbon in a low-temperature plasma. G.K.Moiseev, S.K.Popov, L.A.Ovchinnikova, N.A.Vatolin (Metall. Inst., Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1101-4 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1304-7 (Aug. 1982).
Calculations have been carried out which model the formation of tungsten carbides from tungsten trioxide and carbon at 1000-4000K in a starting medium of Ar. The compositions and content of the components of the phases have been determined, plus the energy expenditures in carrying out the process. It has been found that at various starting concentrations of the reducing agent, up to 3100K, mixtures of crystalline WC and α-W_2C with carbon are formed; above about 3100K, liquid solutions of carbon in tungsten. In an $Ar+H_2$ plasma at 3000K and a treatment time of 180 sec, experiments have been performed on the preparation of tungsten carbides from tungsten trioxide and carbon at various ratios of these materials. It has been found that mixtures of WC, α-W_2C, and carbon are formed. Ratios of the carbides in these mixtures have been calculated from analytical chemical data. The results of the calculations and the experimental figures agree satisfactorily with one another. (8 refs.)

109725 Negative ion formation in collision of electron with H_2 and isotopes. S.Bhattacharyya (Dept. of Phys., Gokhale Coll., Calcutta, India), L.Chatterjee, T.Roy.
Indian J. Phys. Part B, vol.57B, no.2, p.184-9 (April 1983). [received: Sept. 1983]
Cross-section for unstable H^- ion formation from dissociative attachment (DA) of H_2 and D^- formation from D_2 are computed using non-relativistic quantum electrodynamics. Peaks are observed in the DA of H_2 and D_2 in the range 12 to 12.5 eV, corresponding experimental peaks (Rapp, Sharp and Briglia 1965) being observed in the range 10-12 eV. Experimental effect of smaller probability with heavier mass is also confirmed. (14 refs.)

109726 Energy and time dependence of the decay processes of toluene molecular cations. R.Bombach, J.Dannacher, J.-P.Stadelmann (Phys.-Chem. Inst., Univ. Basel, Basel, Switzerland).
J. Am. Chem. Soc. (USA), vol.105, no.13, p.4205-11 (29 June 1983).
The breakdown diagram of toluene cation has been determined by time-resolved He Iα photoelectron-photoion coincidence spectroscopy. The data have been analyzed within the framework of RRKM theory. The most notable outcomes concern: evidence for the entirely statistical nature of the investigated dissociative processes, the rate-energy functions for the formation of tropylium and benzylium cation, the 0K enthalpies of formation of $\Delta H_f{}^{\circ}{}_0$(tropylium cation)$=872\pm6$ kJ/mol and $\Delta H_f{}^{\circ}{}_0$(benzylium cation)$=935\pm9$ kJ/mol, the rate-energy function for the secondary fragmentation of the $C_7H_7^+$ ions, an upper limit of $\Delta H_f{}^{\circ}{}_0(C_5H_5^+)=1034\pm15$ kJ/mol for the product ion of this latter reaction, and a quantitative determination of the considerable kinetic shift associated with this secondary process. The partly bimolecular character of ion cyclotron resonance and collisional activation data and the vastly unknown extent of the isomerization of the two isomeric $C_7H_7^+$ primary product ions prevent an extensive comparison with previous results. (32 refs.)

109727 Chemical properties of the gas-phase benzvalene radical cation. D.L.Miller, M.L.Gross (Dept. of Chem., Univ. of Nebraska, Lincoln, NE, USA).
J. Am. Chem. Soc. (USA), vol.105, no.13, p.4239-43 (29 June 1983).
The nature of the gas-phase benzvalene radical cation has been explored by means of comparative ion-molecule reactions studied by Fourier transform mass spectrometry and by comparative collision-induced dissociation spectra obtained by mass spectrometry/mass spectrometry. This C_6H_6 radical cation has a unique structure different from previously studied C_6H_6 radical cations, including ionized benzene. The authors conclude that the structure is similar to that of its neutral precursor. The rate constant of the reaction with neutral butadiene has also been measured and compared with the rate constant of the reaction of ionized fulvene and butadiene. (48 refs.)

109728 On the structure of anions derived from cycloheptatriene in the gas phase. R.L.White, L.Wilkins, J.J.Heitkamp, S.W.Staley (Dept. of Chem., Univ. of California, Riverside, CA, USA).
J. Am. Chem. Soc. (USA), vol.105, no.15, p.4868-70 (27 July 1983).
Fourier transform mass spectrometric studies of hydrogen-deuterium exchange in gas-phase anion-molecule reactions at 6×10^{-6} torr have led to the conclusion that a species with the time-averaged symmetry of the cycloheptatrienyl anion (2) is formed by proton abstraction from cycloheptatriene (1) and then rapidly rearranges to the benzyl anion (3) when OD^- (and possibly ND_2^-) is employed as the abstracting base. These conclusions are supported by the results of 1-7,7-d_2 or 1-1,2,3,4,5,6-d_6 and OH^-, which show the required scrambling of the label in 3, and by results of $C_7H_7^-$ from toluene, which parallel those for $C_7H_7^-$ from 1 with ND_3 of D_2O but not with CD_3OD. Anion 2 undergoes exchange but does not rearrange to benzyl in the presence of CD_3OD. Evidence was not obtained for electron autodetachment from 3 formed from 1. Since such behavior is expected for unimolecular isomerization, it is concluded that rearrangement occurs predominantly in a complex between 2 and water. (18 refs.)

109729 Molecular dynamical studies of the dissociation of a diatomic molecular crystal. I. Energy exchange in rapid exothermic reactions. D.H.Tsai (NBS, Washington, DC, USA), S.F.Trevino.
J. Chem. Phys. (USA), vol.79, no.4, p.1684-97 (15 Aug. 1983).
The authors discuss the results of a study of the exothermic dissociation of a model diatomic molecular crystal. Their main purpose is to investigate the dynamics of energy transport and energy sharing in this system during the dissociation process. The crystal was prepared in a metastable molecular form, in thermal equilibrium at a low initial temperature and pressure. When they heated the system to a higher temperature, at constant volume, they observed thermally initiated dissociations which progressed rapidly to completion. During the dissociation process, they found that the sharing of the potential energy released by the metastable molecules with the rest of the system, and the sharing of the kinetic energy of the dissociated fragments with the kinetic energy of the molecules in the translational degrees of freedom, were rather efficient. But the intra- and intermolecular exchange of the kinetic energy among the various degrees of freedom, namely translation-rotation, translation-vibration, and rotation-vibration was inefficient. Dissociation would occur in one of the regions of high local kinetic energy density, after a molecule in that region had acquired sufficient vibrational energy to break apart, and when the 'caging' effect was favorable to allow the molecule to dissociate. From such a reaction site, and there may be others, the reaction would spread to a neighboring site, and continue this way until all the molecules became dissociated. The induction time showed an approximately logarithmic dependence on the inverse of the temperature of the system after heating. But during the process of rapid dissociation, both the potential energy and the kinetic energy of the system underwent rapid changes, and thermal equilibrium was not reached until the end of the process. (31 refs.)

109730 Electron transfer in the $O_2^+(X^2\Pi_g, v=0\text{-}8)+O_2(X^3\Sigma_g, v=0)$ system. A.E.DePristo (Dept. of Chem., Iowa State Univ., Ames, IA, USA).
J. Chem. Phys. (USA), vol.79, no.4, p.1741-4 (15 Aug. 1983).
Total charge exchange cross sections for the $O_2^+/.O_2$ system were calculated for vibrational levels of the ion up to $v=8$ with ground state neutrals. Four different interaction potentials were utilized, each with different coupling strength between the two electronic arrangements, and the results compared to experimental data. Quantitative agreement was not obtained and qualitative agreement was determined to reflect mainly the use of accurate vibrational overlaps and energy gaps rather than the features of the interaction. The implication of these results for the general theoretical treatment of ion-molecule reactions is discussed briefly. (25 refs.)

109731 Apparatus for high-pressure studies in chemical kinetics in liquid ammonia from −40°C+150°C (233-423K). S.Balt, J.P.Musch, W.E.Renkema, H.Ronde (Dept. of Inorganic Chem., Free Univ., Amsterdam, Netherlands).
J. Phys. E (GB), vol.16, no.9, p.829-31 (Sept. 1983).
A high-pressure apparatus (0-700 MPa) is described that allows kinetic measurements ($t_{1/2}>6$ min) on a routine base in liquid ammonia by in situ spectrophotometry. As an illustration preliminary results on the nitrito-nitro linkage isomerisation reaction of the penta-amminecobalt (III) complex are reported. The activation volume for this reaction, at 5°C (278K) is reported. (4 refs.)

109732 Mathematical model of heterogeneous reactions. V.A.Kirakosyan, A.P.Baskakov (S.M. Kirov Ural Polytech. Inst., Sverdlovsk, USSR).
J. Eng. Phys. (USA), vol.43, no.4, p.1104-10 (Oct. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.4, p.589-97 (Oct. 1982). [received: Sept. 1983]
The authors consider the reactions of a spherical porous particle with gas or liquid in a sufficiently general form, but limit themselves to reactions which do not change the volume of the particle. The macrokinetics of the reaction will be represented as follows. The gaseous or liquid reagent reaches the surface of the particle by convection. Subsequently, it diffuses in the bulk of the solid reagent and simultaneously reacts with it. The gaseous or liquid product which is thus formed escapes from the reaction zone by diffusion and mass exchange into the surrounding medium. In the course of the reaction, the authors neglect the change of volume of the fluid reagent and also the kinetic and diffusion characteristics of the solid. At any point the reaction proceeds until all reagent at this point is used up. As a result, starting from a definite moment of time, a crust of the solid reaction product is formed on the surface of the particle. The thickness of this crust increases as the reaction develops until all volume of the particle undergoes the reaction. (6 refs.)

109733 Experimental evidence of nucleation induced transition in a bistable chemical system. J.C.Roux, P.De Kepper, J.Boissonade (Centre de Recherche Paul Pascal, Univ. de Bordeaux I, Talence, France).
Phys. Lett. A (Netherlands), vol.97A, no.4, p.168-70 (22 Aug. 1983).
It is experimentally shown that a chemical nonequilibrium bistable system presents metastability and stirring rate sensitivity in full agreement with theoretical predictions of nucleation induced transitions. (16 refs.)

109734 The unified thermal and chain branching model of hydrocarbon oxidation in a well stirred continuous flow reactor. I.Gonda, B.F.Gray (Dept. of Pharmacy, Univ. of Aston, Birmingham, England).
Proc. R. Soc. London Ser. A (GB), vol.389, no.1796, p.133-52 (8 Sept. 1983).
The Gray-Yang 'skeleton' model of hydrocarbon oxidation, which unified the thermal and chain branching theories of hydrocarbon oxidation, is analysed in detail in order to probe its ability to account for the recent experimental observations in continuously stirred tank reactors. Using rigorous mathematical analysis, the nature of the thermokinetic steady states is investigated, and particular attention is paid to the existence of stable limit cycles originating from supercritical Hopf bifurcations. These oscillations representing the 'cool flames' disappear at the low temperature limit via limit cycle-saddle point bifurcations. The origin of 'two-stage' ignitions is traced to these bifurcations; the computed trajectories exhibit 'shoulders' characteristic of such ignitions. When the ambient temperature is traversed slowly upward or downward, rapid transitions between quasi-steady states occur. The system shows hysteresis in the transitions between oscillatory and non-oscillatory steady states. (23 refs.)

109735 A study of the nonadiabatic effects in the Li-Li_2^+ system: typical minimum energy paths for the reaction $Li+Li_2^+\rightarrow Li_3^+$. J.Vojtik, A.Krtkova, R.Polak (J. Heyrovsky Inst. of Phys. Chem. & Electrochem., Czechoslovak Acad. of Sci., Prague, Czechoslovakia).
Theor. Chim. Acta (Germany), vol.63, no.3, p.235-43 (1983).
Mutual arrangement and nonadiabatic coupling between the lowest two singlet potential energy surfaces of the Li_3^+ system are studied along typical ground-state minimum energy paths for the reaction $Li+Li_2^+\rightarrow Li_3^+$. The potentials and nonadiabatic coupling matrix elements are obtained using the diatomics-in-molecules method. The relative Li-Li_2^+ motion along the pathways is predicted to be inefficient in causing nonadiabatic transitions from the ground state to the first excited state of the system. (19 refs.)

109736 Kinetics of the interaction of a liquid diffusing into another one as studied by reflection spectroscopy (ATR). A.Z.Trifonov (Inst. of Organic Chem., Bulgarian Acad. of Sci., Sofia, Bulgaria), B.K.Shishedjiev, R.B.Kuzmanova, R.Stefanova.
Waerme- & Stoffuebertrag. (Germany), vol.17, no.4, p.237-40 (1983).
An approach is offered for determining the reaction rate constant (k) between two liquid substances, the one penetrating into the other. The procedure is based on the experimental measurement of the diffusion coefficient ($\mathcal{D}$). As

model reaction the isotopic exchange process in the ketone octanone-2 molecule is chosen, whose active hydrogen atoms undergo deuteration by the strong base trioctyl-methyl-ammonium deuteroxide (TOMA-OD). The diffusion coefficient of the penetrating TOMA-OD, when this reaction takes place, and the rate constant of the latter are determined by an attenuated total reflection (ATR) spectroscopic method on the grounds of appropriate mathematical modeling. 82.35 POLYMER REACTIONS AND POLYMERIZATION

109737 Plasma polymerization of ethane. I. Experimental studies of effluent gas composition and polymer deposition rates. R.J.Jensen, A.T.Bell, D.S.Soong (Dept. of Chem. Engng., Univ. of California, Berkeley, CA, USA).
Plasma Chem. & Plasma Process. (USA), vol.3, no.2, p.139-61 (June 1983).
The plasma polymerization of ethane was studied in a flow reactor of rectangular cross section. The plasma was sustained between parallel-plate electrodes by an F generator operating at 13.56 MHz. The composition of the gas leaving the reactor was analyzed by gas chromatography. Polymer deposition rates were measured as a function of axial position in the reactor, using a quartz-crystal microbalance. The effluent gas is composed primarily of unreacted C_2H_6 and H_2. Significant concentrations of CH_4, C_2H_4, C_2H_2, and C_3H_8, and small amounts of C_3H_6, i-C_5H_{12}, and n-C_5H_{12} are also observed. The distribution of these products is a strong function of the discharge power and of the gas pressure and residence time in the plasma. These experimental variables also affect both the rate of polymer deposition and the shape of the deposition profile along the reactor axis. (29 refs.)

109738 Plasma polymerization of ethane. II. Theoretical analysis of effluent gas composition and polymer deposition rates. R.J.Jensen, A.T.Bell, D.S.Soong (Dept. of Chem. Engng., Univ. of California, Berkeley, CA, USA).
Plasma Chem. & Plasma Process. (USA), vol.3, no.2, p.163-92 (June 1983).
For pt.I see ibid., vol.3, no.2, p.139 (1983). A theoretical model has been developed to describe the deposition of polymer occurring in a capacitatively coupled, low-pressure RF discharge sustained in ethane. The reaction mechanism chosen for this model assumes that polymer formation is controlled by the formation of free radicals in the plasma and the subsequent reaction of these species at the surface of the electrodes used to sustain the plasma. Convective and diffuse transport is taken to occur in the direction parallel to the electrodes. Diffusive transport perpendicular to the electrodes is considered to be rapid, and hence the gradients in this direction are taken to be negligible. Both the composition of the gas leaving the plasma reactor and the axial profile of polymer deposition rate within the reactor, observed experimentally, are predicted accurately by the model. Results obtained from the model have also been used to estimate the kinetic chain length and degree of unsaturation in the polymer. Both predictions are in reasonable agreement with experimental observations. (78 refs.)

82.40 CHEMICAL KINETICS AND REACTIONS: SPECIAL REGIMES

109739 A model for mixing with fast chemical reactions. V.G.Jenson (Dept. of Chem. Engng., Univ. of Birmingham, Birmingham, England).
Chem. Eng. Sci. (GB), vol.38, no.8, p.1151-7 (1983).
A previously published model of an unmixed spherical eddy containing an immobile reactant surrounded by a restricted volume of well mixed fluid has been improved by allowing all of the reactants and products to diffuse equally both within the eddy and in the surrounding fluid. The predicted development of the concentration profiles for a competitive consecutive second order reaction scheme is illustrated and shown to be physically reasonable. The final comparison with published experimental data confirms that the model is capable of predicting the results without the necessity of fitting any parameter values other than choosing the Kolmogoroff microscale for the diameter of the eddies. (9 refs.)

109740 Applicability limits of the stationary combustion model in the study of explosive initiation. S.G.Andreev, A.N.Isaev, V.S.Solov'ev, A.I.Chernov.
Combust. Explos. & Shock Waves (USA), vol.18, no.6, p.613-18 (Nov.-Dec. 1982). Translation of: *Fiz. Goreniya & Vzryva (USSR)*, vol.18, no.6, p.3-9 (Nov.-Dec. 1982).
Using the theory of stationary combustion, the authors establish limiting values for the parameters of hearth decomposition of an explosive. Use of the stationary combustion model permits qualitative analysis of the features of explosive combustion upon shock loading. (11 refs.)

109741 Erosion combustion of a solid fuel for various gas flow temperatures. A.M.Lipanov, I.G.Rusyak.
Combust. Explos. & Shock Waves (USA), vol.18, no.6, p.618-23 (Nov.-Dec. 1982). Translation of: *Fiz. Goreniya & Vzryva (USSR)*, vol.18, no.6, p.9-14 (Nov.-Dec. 1982).
In the theory of erosion combustion, turbulences in the flame zone is responsible for increasing the combustion rate of a solid fuel at high gas speeds. The authors examine the erosion combustion for various incident temperatures within the framework of the existing concepts. Two limiting cases are considered: 1) low pressures $p=2$-8 MPa, where there are two zones of heat production in the combustion region, and the combustion mechanism can be considered approximately as due to two successive overall reactions; 2) pressures $p>8$ MPa, where the two stages fuse into one and the combustion can be represented as due to a single overall reaction. (11 refs.)

109742 Dynamics of gas combustion in closed vessels with various laws of flame-surface variation. V.S.Babkin, P.K.Senachin, T.V.Krakhtinova.
Combust. Explos. & Shock Waves (USA), vol.18, no.6, p.623-8 (Nov.-Dec. 1982). Translation of: *Fiz. Goreniya & Vzryva (USSR)*, vol.18, no.6, p.14-20 (Nov.-Dec. 1982).
The authors investigate the general properties and features of the dynamics of gas combustion with different laws of the variation in the flame surface. The model laws of the variation in flame surface may expediently be chosen in the form of laws realized in the propagation of diverging of converging flames with spherical, cylindrical, and plane symmetry. Such flames give broad and, at the same time, systematic variations in the flame-front areas, imitating the broad range of real processes. (14 refs.)

109743 Flame zone in gas combustion in an inert porous medium. A.A.Korzhavin, V.A.Bunev, R.Kh.Abdullin, V.S.Babkin.
Combust. Explos. & Shock Waves (USA), vol.18, no.6, p.628-31 (Nov.-Dec. 1982). Translation of: *Fiz. Goreniya & Vzryva (USSR)*, vol.18, no.6, p.209-3 (Nov.-Dec. 1982).
The extent of the combustion zone of a gas mixture in a porous medium is determined, and a deduction is made that the combustion zone also contains products being cooled, in addition to chemical reaction foci. On the basis of the data obtained, the extent of the combustion zone is substantially greater than the thickness of the laminar flame front. It is deduced that the flame propagation regime in a porous medium is turbulent in nature. (6 refs.)

109744 Experimental study of stationary flame propagation in a tube under conditions of weightlessness. V.P.Samsonov, S.A.Abrukov, A.E.Davydov, V.A.Danilkin, V.Ya.Tyameikin.
Combust. Explos. & Shock Waves (USA), vol.18, no.6, p.650-2 (Nov.-Dec. 1982). Translation of: *Fiz. Goreniya & Vzryva (USSR)*, vol.18, no.6, p.45-8 (Nov.-Dec. 1982).
The authors investigate the changes in form of a laminar flame under the influence of natural thermal convection with stationary propagation in a vertical tube under normal gravitational conditions and under conditions of weightlessness, in which case convection is absent. (12 refs.)

109745 Existence and uniqueness of the steady solution of the equations of the problem of exothermal-wave propagation in a two-phase medium. P.L.Gusika.
Combust. Explos. & Shock Waves (USA), vol.18, no.6, p.690-5 (Nov.-Dec. 1982). Translation of: *Fiz. Goreniya & Vzryva (USSR)*, vol.18, no.6, p.90-6 (Nov.-Dec. 1982).
The author shows that the question of the existence and uniqueness of the solution of the system of equations as a whole, may be answered in the affirmative if it is proved that the specified initial and thermophysical parameters correspond to a unique value of the velocity and a unique solution of the equations for the reaction zone, satisfying the conditions at its boundaries with the heating zone and the thermal relaxation zone. (12 refs.)

109746 Method of calculating limits of stabilization of a flame of inhomogeneous mixtures traveling over a poorly streamlined body. V.L.Apollonov, V.N.Gruzdev, A.V.Talantov (A.N. Tupoleva Kazan Polytech. Inst., Kazan, USSR).
J. Eng. Phys. (USA), vol.43, no.4, p.1068-72 (Oct. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.4, p.548-54 (Oct. 1982). [received: Sept. 1983]
A method has been developed for calculating the range of stabilization of a flame of inhomogeneous mixtures with allowance for characteristics of the atomization, vaporization, and distribution of the fuel in the flow. (8 refs.)

109747 Fire and combustion systems. J.R.Lloyd (Dept. of Aerospace & Mech. Engng., Univ. of Notre Dame, Notre Dame, IN, USA).
Mech. Eng. (USA), vol.105, no.6, p.40-3 (June 1983).
The mathematical modeling of fires focuses on radiation, turbulence, and plumes. Topics such as spray combustion, turbulence effects on combustion, and coal combustion are but the tip of the iceberg. (no refs.)

109748 Gas-phase chemiluminescent reactions of ozone with monoterpenes. P.K.Arora, J.P.S.Chatha, K.G.Vohra (Air Monitoring Section, Bhabha Atomic Res. Centre, Bombay, India).
Chem. Phys. Lett. (Netherlands), vol.100, no.1, p.93-8 (26 Aug. 1983).
Chemiluminescent reactions of ozone with monoterpenes such as linallol, geranoil, d-limonene and α-pinene have been studied in the gas phase at low pressures. Methylglyoxal phosphorescence has been observed in the first two reactions. Emissions from $HCHO(^1A_2)$ are observed in the reaction of ozone with d-limonene and formation of excited glyoxyl is found to be first order in ozone. The reaction of ozone with β-pinene gives rise to emission from a α-dicarbonyl compound and this is found to be first order in ozone. The mechanisms for the formation of excited species are proposed. (4 refs.)

109749 Luminescence of I_2/Ar mixture flowing out of a quenching setup at atmospheric pressure. V.E.Nosenko, I.I.Borisov, V.V.Naumov, V.A.Reisig, A.V.Solov'ev.
Combust. Explos. & Shock Waves (USA), vol.18, no.6, p.657-61 (Nov.-Dec. 1982). Translation of: *Fiz. Goreniya & Vzryva (USSR)*, vol.18, no.6, p.53-7 (Nov.-Dec. 1982).
The authors show that as a result of nonadiabatic cooling of the thermally excited mixture I_2/Ar in the process of transonic flow through a quenching setup at atmospheric pressure, recombination radiation of molecular iodine in the green region of the spectrum was obtained. (19 refs.)

82.45 ELECTROCHEMISTRY AND ELECTROPHORESIS

(see also 66.10 Ionic conduction in liquids; for electro-osmosis, see 82.65)

109750 Current distribution on the surface electrode, immersed in an aqueous medium, when this surface is partly subjected to a mechanical abrasion. L.Chincholle (Univ. Paris VI, Paris, France).
C.R. Seances Acad. Sci. Ser. II (France), vol.296, no.20, p.1579-82 (6 June 1983). In French.
When a metal is dissolved in an aqueous medium, electrons are set free. If the film protecting the surface is permanently and regularly taken away, an electric current which can be analysed results. Then the electrode works as an electron generator with the properties of a classical, constant current supply. (no refs.)

109751 Influence of evolution of hydrogen on the value of the slope of polarization curves during cathodic deposition of metals of the iron group. V.M.Nagirnyi, V.M.Chaikovskaya.
Elektron. Obrab. Mater. (USSR), no.3, p.57-9 (1983). In Russian. English translation in: *Electrochem. Ind. Process. & Biol. (GB)*
Change in a fraction of the current of the hydrogen-evolution reaction during change in the density of the polarizing current leads to a deviation of the slope of the polarization curves from the true value. In order to obtain an approximate evaluation of this deviation it is necessary to allow for a correction to the change in a fraction of the current of the secondary reaction in the range of current density being measured, which can assume a value from 0 to 0.5. (7 refs.) *A.J.B.*

109752 Electrode wear in the treatment of low-carbon steel in electrolytic plasma in an anodic process. E.Resner, G.Marks, V.A.Zaitsev, A.M.Sukhotin.
Elektron. Obrab. Mater. (USSR), no.3, p.59-61 (1983). In Russian. English translation in: *Electrochem. Ind. Process. & Biol. (GB)*
It is shown that the wear of an electrode increases with increase in the concentration of hydrochloric acid and acetone, particularly at voltages corresponding to electrohydrodynamic conditions (325 V), and that the current efficiency under such conditions always exceeds 100%, independently of the duration of the tests. It is suggested that processes leading to wear of the anode in electroplasma heating are close in nature to the high-temperature oxidation of steel with the formation of FeO. (7 refs.) *A.J.B.*

109753 A laboratory testing apparatus for high speed electrolytes. F.Friedrich, C.J.Raub.
Galvanotechnik (Germany), vol.74, no.5, p.521-2 (May 1983). In German.
For the study of electrolytes with high rates of deposition, and electrolytes for selective plating in which the plating rate of the electrolyte is of special importance, a laboratory apparatus has been designed which enables the plating parameters to be simulated. The cathode can be used as a baffle which is sprayed. The anode acts as a nozzle. The apparatus can be employed in the service laboratory and elsewhere for the development of electrolytes. (3 refs.)

109754 The testing of electrodes for alkaline solution water electrolysis. J.Balajka (Res. Power Inst., Bratislava, Czechoslovakia).
Int. J. Hydrogen Energy (GB), vol.8, no.10, p.755-62 (1983).
The alkaline solution water electrolysis with the use of off-peak energy from nuclear power stations is proposed for hydrogen production in the initial stages of hydrogen energy system development. The energy consumption of this process could be reduced by the use of electrode improvements for both the anode and the cathode of bipolar electrolytic cells. These improvements comprise preparing an electrocatalytic surface layer, or the increase of an effective surface area by the use of Teflon-bonded electrodes or a Ni-layer on the asbestos diaphragm surface. The Teflon-bonded electrodes achieved the best results in the laboratory static test cell. In actual electrolytic cells difficulties with gas evolution arose. The simple and cheap electrode improvements, which were verified by the laboratory tests as well as by the test in the electrolyser module of 300 g H_2/h output were as follows: (1) Ni screen treated with a boiling solution of Na_2S in order to obtain a catalytically active surface layer of NiS_x, used as cathode; (2) Ni screen treated by thermal decomposition of Ni and Co nitrates in a molar ratio of 1:2 in order to obtain the spinel-like structure mixed oxide layer of $NiO.CO_2O_3$ as anode. This layer promotes resistance of the electrode surface to hot alkaline oxygen rich environments as well as the catalytic activity of the Ni screen electrode surface. (15 refs.)

109755 Iron oxide electrodes for photoelectrolysis of water. N.Giordano, E.Passalacqua, V.Antonucci (Istituto CNR di Ricerche sui Metodi e Processi Chimici per la Trasformazione e l'Accumulo dell'Energia, Messina, Italy), J.C.J.Bart.
Int. J. Hydrogen Energy (GB), vol.8, no.10, p.763-6 (1983).
Results of photoassisted electrolysis of water over iron electrodes oxidized in air between 200° and 1300°C are compared. Maximum photocurrents are found for electrodes activated at low temperatures (200-400°C). The current density greatly diminishes in the presence of a thick α-Fe_2O_3 overlayer. (25 refs.)

109756 Photomodulated and one-beam and two-beam potential modulated photoelectrochemical spectroscopies. J.F.McCann (School of Phys., Univ. of New South Wales, Kensington, NSW, Australia), M.Skyllas-Kazacos.
J. Electrochem. Soc. (USA), vol.130, no.7, p.1510-13 (July 1983).
Three techniques for measuring interband transitions in semiconductor electrodes in electrolytes are described. These are photomodulated and one-beam and two-beam potential modulated spectroscopies. The usefulness of the techniques is demonstrated by using each technique to measure the direct band gap transition for a single crystal n-CdSe electrode in a 1M S-1M Na_2S-1M NaOH electrolyte. The difference between a two-beam potential modulated photoelectrochemical spectrum and a corresponding one-beam spectrum is interpreted to be a measure of minority carrier recombination inside and at the surface of the semiconductor electrode. Peaks in the modulated photocurrent spectra at the direct bandedge of CdSe are attributed to field induced absorption effects. (15 refs.)

109757 NMR-electrolysis combined method (NMREL). Basic principles and some applications. V.G.Mairanovsky, L.Yu.Yusefovich, T.M.Filippova (All-Union Res. Vitamin Inst., Moscow, USSR).
J. Magn. Resonance (USA), vol.54, no.1, p.19-35 (Aug. 1983).
Electrolysis conducted directly in a sample tube of an NMR spectrometer (NMREL) has been applied to various kinetic and analytical problems and to the study of the mechanisms of electroorganic reactions. The kinetics of anion-radical decay was studied for benzoquinone, ubiquinone Q_0, ρ-nitrotoluene, 4-nitroorthoxylene, and ρ-toluenenitrile; and kinetics of electron transfer was studied for the symmetric system: $M^{\cdot -}+M \rightleftharpoons M+M^{\cdot -}$. Three NMREL techniques were tested to find the rate constants in the series of the compounds. Asymmetric electron transfer $M^{\cdot -}+N \rightleftharpoons M+N^{\cdot -}$ was studied for

endoergic reactions leading to both stable $N^{\cdot}$ and unstable $N^{\cdot}$, and the electron transfer and $N^{\cdot}$-decay rate constants were estimated. An analytical treatment has been proposed based on NMR signal broadening due to electron exchange, brought about by an electrochemical reaction. The potentialities of this treatment were demonstrated by the analysis of a 3-nitroorthoxylene+xylene mixture: the presence of xylene was detected accurately even for 20-fold excess of the other component. For electroreduction of vitamin A in DMF-d_6, NMREL has found an earlier unknown axerophtene isomer along with the usual product. (25 refs.)

109758 Magnetoelectrolysis. T.Z.Fahidy (Dept. of Chem. Engng., Univ. of Waterloo, Waterloo, Ontario, Canada).
J. Appl. Electrochem. (GB), vol.13, no.5, p.553-63 (Sept. 1983).
The influence of an imposed magnetic field on electrochemical processes is reviewed. In particular, the effects of combined electric/magnetic fields on electrolyte properties, mass transport, electrode kinetics and the quality of electroplated metals is emphasized. (101 refs.)

109759 Energy consumption of aluminium smelting cells containing solid wetted cathodes. R.C.Dorward (Kaiser Aluminum & Chem. Corp., Pleasanton, CA, USA).
J. Appl. Electrochem. (GB), vol.13, no.5, p.569-75 (Sept. 1983).
Tests with 10 kA pilot cells show that substituting a wetted, dimensionally stable cathode for the turbulent metal cathode allows the anode-cathode distance (ACD) to be decreased, with an attendent voltage reduction of about 1 V, depending on current density. Since high current efficiency is retained, specific energy consumption is decreased by about 20%. These savings are not as great as anticipated, however, because the effective electrical resistivity of the electrolyte increases as the ACD is lowered. This effect is ascribed to an increased void fraction of anode gas in the interpolar space, which appears to be dependent on anode size. (15 refs.)

109760 A new electrochemical technique for bleaching cellulose pulp. M.N.Nassar, O.A.Fadaly (Dept. of Chem. Engng., Tech. Univ. of Nova Scotia, Halifax, Nova Scotia, Canada), G.H.Sedahmed.
J. Appl. Electrochem. (GB), vol.13, no.5, p.663-7 (Sept. 1983).
A study of electrochemical bleaching of cellulose pulp was carried out in an electrolyte cell composed of a horizontal graphite anode and a parallel stainless screen steel cathode, using NaCl as electrolyte. Variables studied were: current density, sodium chloride concentration, pulp concentration, pH and temperature. The rate of bleaching was found to increase with increasing current density, salt concentration and temperature. The rate of bleaching was found to decrease with increasing pH and pulp concentration. Energy consumption ranged from 0.1 kWh kg^{-1} (pulp) to 1.75 kWh kg^{-1} (pulp), depending on current density and degree of bleaching. The quality of electrochemically bleached pulp was found to compare favourably with that of chemically bleached pulp. (6 refs.)

109761 Reverse electrodialysis. Electric energy detained from mixing of solutions of different salinity. R.Audinos (Lab. de Chimie Phys. et Electrochimie, Univ. Paul Sabatier, Toulouse, France).
J. Power Sources (Switzerland), vol.10, no.3, p.203-17 (Aug. 1983). In French.
It is possible to obtain, in the form of electric power, the energy of mixing of two solutions of different salinity by reverse electrodialysis. The laboratory electrodialyzer used was fitted in turn with two different pairs of permselective membranes, AMV-CMV and ARP-CRP. Solutions of $ZnSO_4$ (216/18.8, 201/34.6, 110/40.2 and 127/14.2 g/l) and of NaCl (245/13 and 250/1 g/l) were used in batch recirculation. Only NaCl solutions (294/1, 295/1 and 150/1 g/l) were used in continuous flow operation. Results show the influence of type of membrane, composition and concentration of solutions and type of electrode. The maximum power obtained is 400 nW/m^2. (14 refs.)

109762 Peculiarities of the electroreduction of aluminum from high-temperature aluminum chloride melts. Yu.K.Delimarskii, V.F.Makogon (Inst. of General & Inorganic Chem., Acad. of Sci., Kiev, Ukrainian SSR).
Sov. Electrochem. (USA), vol.18, no.10, p.1232-6 (Oct. 1982). Translation of: *Elektrokhimiya (USSR)*, vol.18, no.10, p.1386-90 (Oct. 1982).
The main results obtained in a study of the cathodic process of reduction of aluminium chloride at the temperature 700-800°C, i.e., above the melting point of aluminum, are presented. The formulation of the question is due to searches for possibilities of electrolysis of aluminum chloride. An electrochemical substantiation of the use of the electrolyte, electrodes, and methods was performed. The influence of the cationic composition of the electrolyte on the kinetics and mechanism of the electrode process was studied. The influence of side processes on them was evaluated. (14 refs.)

82.50 PHOTOCHEMISTRY AND RADIATION CHEMISTRY

(see also 33.50 Fluorescence, phosphorescence; radiationless transitions)

109763 Production and detection of energetic species by laser photolysis and detection techniques. J.R.McDonald (Chem. Div., Naval Res. Lab., Washington, DC, USA).
AIP Conf. Proc. (USA), no.100, p.307-16 (1983). (Topical Meeting on Excimer Lasers, Incline Village, NV, USA, 10-12 Jan. 1983).
The impact of lasers on photochemistry and spectroscopy has had an evolutionary effect. The author demonstrates the use of laser techniques adapted to the study of reaction chemistry and spectroscopy by discussion of a few recent experiments. The experiments involve the study of the spectroscopy or reactions of a group of energetic short-lived molecules—molecular free radicals. The author takes advantage of the high brightness short pulse capability of ultraviolet lasers to create the radicals and the tunability and narrow band width capability of dye lasers to probe the internal states and evolutionary processes of these reactive systems. In many instances the use of laser photolysis techniques has allowed the author to cleanly produce a radical for study which has not been feasible by more classical methods. In other cases, the use of laser induced fluorescence (LIF) allows one to uniquely follow the reactive fate of a single species in a mixture of reactive intermediates which is too complex to be studied by traditional product analysis techniques. (6 refs.)

109764 Correlation between the photoelectron emission and photooxidation threshold energies of a solute in the condensed phase. T.B.Truong (Lab. de Phys.-Chimie des Rayonnements, Univ. Paris-Sud, Orsay, France).
Chem. Phys. Lett. (Netherlands), vol.100, no.1, p.76-82 (26 Aug. 1983).
The photoelectron emission threshold energy E_t of a solute is related to its photooxidation threshold energy I_S by the following correlation: $E_t=I_S-P_--V_0$, where V_0 is the solvent conduction band depth and $P_-=-(e^2/2r)(1-D_{op}{}^{-1})$ is the polarization energy of the mobile electron with r derived from a solute-solvent cage charge-transfer model. For the first oxidation state, $A \rightarrow A^+ + e^-$, the E_t of a solute A differs from its gas-phase oxidation energy by a solute-solvent cage interaction terms ΔH_{CT}. (19 refs.)

109765 Deuterium separation and infrared photochemistry in CF_2HCl. J.E.Moser, P.Morand, R.Duperrex, H.van den Bergh (Inst. de Chimie Phys., Ecole Polytech. Federale, Lausanne, Switzerland).
Chem. Phys. (Netherlands), vol.79, no.2, p.277-88 (1 Sept. 1983).
Deuterium separation has been demonstrated by studying the infrared multiphoton dissociation of CF_2DCl and CF_2HCl/CF_2DCl mixtures. It is shown how the parameters which control the infrared photochemistry of CF_2DCl such as the temperature and the pressure, as well as the wavelength, the energy fluence and the intensity of the laser pulse, can be optimised for deuterium separation. Infrared analysis of the disappearing CF_2DCl and CF_2HCl peaks indicates isotopic selectivities in excess of 10^4. Dissociation yields of up to 5% are observed at fluences around 6 J cm^{-2} with 30 ns pulses at pressures in the range 0.3 to 150 Torr. A new route is presented for redeuteration of the deuterium-depleted CF_2HCl to natural abundance by way of high-temperature exchange in the gas phase. (49 refs.)

109766 Effect of a polar substituent on olefin triplet lifetime. R.A.Caldwell, M.Singh (Dept. of Chem., Univ. of Texas, Richardson, TX, USA).
J. Am. Chem. Soc. (USA), vol.105, no.15, p.5139-40 (27 July 1983).
The lifetimes of olefin triplets are important parameters for the study of the vast number of olefin triplet-state isomerizations and cycloadditions. They also serve as models for intersystem crossing rates in flexible organic triplet biradicals and biradicaloids. Several structural factors are expected to influence intersystem crossing in and thus the lifetimes of such species: interterminal distance, relative orientations of the orbitals bearing the unpaired electrons, and the degree of ionic character in the singlet wave function. The authors have sought systems that can test the importance of these factors one by one. They report the triplet lifetimes of chalcones with a wide range of polar substituents, presumably a valid test of the last factor. They observe essentially no effect, in contrast to what might have been expected. (19 refs.)

109767 Correlation effects in vibrational hole burning. J.Friedrich, D.Haarer (Phys. Inst., Univ. Bayreuth, Bayreuth, Germany).
J. Chem. Phys. (USA), vol.79, no.4, p.1612-15 (15 Aug. 1983).
The paper presents a theoretical model which describes correlation effects in nonresonant photochemical holes. The model calculations are compared with experiments of photochemical hole burning (PHB) in electronically excited vibrational states of 1,4-dihydroxyanthraquinone (DAQ) in alcohol glass matrices. Vibrational hole burning shows some specific features such as the occurrence of several nonresonant holes in the electronic origin which differ considerably in their widths and integrated optical density from the resonant hole. The difference in linewidth is related to a vibrational inhomogeneity which is superimposed on the observed relaxation broadening. The experiments show that the vibrational inhomogeneity is not uniform but varies with the vibrational state. (14 refs.)

109768 Reversible, light-induced isomerization of matrix-isolated molecules. Nitrosomethanol. R.P.Muller, J.R.Huber (Phys.-Chem. Inst., Univ. Zurich, Zurich, Switzerland).
J. Phys. Chem. (USA), vol.87, no.14, p.2460-2 (7 July 1983).
A reversible, light-induced isomerization of the previously unknown nitrosomethanol molecule $[H_2C(OH)(NO)]$ has been investigated by IR spectroscopy in an argon matrix. Two distinct conformers of the molecule—the intramolecularly hydrogen bonded cis form and an open-chain trans form—were reversibly interconverted by selective excitation with green and red light, respectively. (10 refs.)

109769 Intramolecular donor-acceptor systems. VII. Solvent dielectric relaxation effects on the photophysics of 6-(phenylamino)-*N*,*N*-dimethyl-2-naphthalenesulfonamides. E.M.Kosower (Dept. of Chem., Tel-Aviv Univ., Tel-Aviv, Israel), H.Kanety, H.Dodluk, G.Striker, T.Jovin, H.Boni, D.Huppert.
J. Phys. Chem. (USA), vol.87, no.14, p.2479-84 (7 July 1983).
For pt.VI see Chem. Phys. Lett., vol.84, p.48 (1981). Excitation of 6-[(4-X-phenyl)amino]-*N*,*N*-dimethyl-2-naphthalenesulfonamides (X=Br, H, CH_3,

OCH_3) produces a nonplanar S_1 ($S_{1,np}$) state which undergoes intramolecular electron transfer in a wide polarity range of solvents to form a charge-transfer S_1 state ($S_{1,ct}$), the processes being defined by emission maxima and fluorescence quantum yields as a function of solvent polarity and phenyl substituent. From the variation of fluorescence lifetimes with solvent polarity using dioxane-water and dioxane-methanol mixtures, solvent dielectric relaxation rates are implicated as the controlling feature for the nonradiative electron-transfer process which quenches the charge-transfer fluorescence and reforms the S_0 state. (12 refs.)

109770 Pulse-rate effects in the photochemistry of gas-phase bromobenzene ions. A study of ion relaxation mechanisms. R.C.Dunbar (Chem. Dept., Case Western Reserve Univ., Cleveland, OH, USA).
J. Phys. Chem. (USA), vol.87, no.16, p.3105-8 (4 Aug. 1983).
Two-photon photochemistry of gas-phase bromobenzene ion using a repetitively pulsed light source was studied in the ion cyclotron resonance (ICR) spectrometer and modeled by numerical integration of the kinetic equations. Theoretical modeling and experiment were in excellent agreement, showing as expected that effects of pulse rate depend strongly on the relation of pulse rate and ion relaxation rates. Effects attributable to infrared radiative relaxation of ions were clearly evident, and this relaxation was found to have a rate between 1 and 3 s^{-1}. (14 refs.)

109771 Radical cations of halogenobenzenes. An electron spin resonance study. P.Maj, A.Hasegawa, M.C.R.Symons (Dept. of Chem., Leicester Univ., Leicester, England).
J. Chem. Soc. Faraday Trans. I (GB), vol.79, pt.8, p.1931-8 (Aug. 1983).
Exposure of dilute solutions of a range of halogenobenzene derivatives in fluorotrichloromethane to ^{60}Co γ-rays at 77K gave the corresponding radical cations, characterized by their ESR spectra. The approximate π spin densities on halogen estimated therefrom increased from ca. 8% for PhF^+ to 23% for $PhCl^+$, 30% for $PhBr^+$ and 46% for PhI^+, in accord with the fall in ionization potential for this series of halogens. For *p*-fluorotoluene well defined methyl- and ring-proton hyperfine coupling was obtained, the methyl-proton coupling (19 G) being slightly greater than that for the toluene cation (18.5 G). For $PhBr^+$, replacement of para-hydrogen by Br, OH and SH gave a steady fall in spin density on bromine, reflecting increasing π-delocalization onto the para-substituent. For concentrated solutions of the chloro-, bromo- and iodo-derivatives dimer cations were detected. (38 refs.)

109772 Selectivity of muonic radical formation in methyl-substituted buta-1,3-dienes. E.Roduner (Phys.-Chem. Inst., Zurich Univ., Zurich, Switzerland), B.C.Webster.
J. Chem. Soc. Faraday Trans. I (GB), vol.79, pt.8, p.1939-50 (Aug. 1983).
Muonium-substituted free radicals are observed by muon spin rotation when polarised positive muons are stopped in several substituted liquid dienes. There is a preference for the most energetically stable radical to be formed. The selectivity of formation obeys the Evans-Polanyi relation between activation energies and heats of reaction. Two models are discussed for the radical-formation process and upper limits are set on the lifetimes of possible muonic radical precursors: 20 ps for $Mu(\equiv\mu^+e^-)$ and 2 ns for μ^+ in diamagnetic environments. (36 refs.)

109773 The effect of gold salts on the chemical mechanisms of photographic sulfur sensitization of silver halide photoemulsions: stabilization of adsorbed sulfide at the crystal surface. D.J.Cash (Minnesota 3M Res., Harlow, England).
Photogr. Sci. & Eng. (USA), vol.27, no.4, p.156-60 (July-Aug. 1983).
Different reactions occurring in gold and sulfur sensitization have been resolved. These were (1) sulfide formation, (2) sulfur sensitization due to silver sulfide specks, (3) gold sensitization due to gold-silver sulfide specks, (4) digestion fog due to sulfide specks, (5) premature fog due to reduction of gold to the elemental state. Kinetic measurements indicated that the essential chemical mechanism of sulfur sensitization, hence its photographic corollaries, was conserved in the presence of gold ion. The gold sensitization could be performed during or after the sulfur sensitization. With fast sulfide formation the presence of gold caused a decrease in the rate of photographic digestionl. This was attributed to retardation of sulfide speck growth by gold ion analogous to that by organic photographic stabilizers. A mechanism was suggested which involved the coordination of adsorbed sulfide by gold ion at kink sites or coordinated with the methionine residue of gelatin. Fog due to elemental gold could be completely removed by oxidizing agents with no loss of sensitization. This supported a gold (+ sulfur) sensitization mechanism due to gold ions involving the formation of mixed gold-silver sulfide specks. (35 refs.)

109774 Redistribution of development centers after sulfur sensitization. V.Zhelev, Y.Astrov (Central Lab., Bulgarian Acad. of Sci., Sofia, Bulgaria).
Photogr. Sci. & Eng. (USA), vol.27, no.4, p.160-70 (July-Aug. 1983).
Observations made under a variety of conditions suggest that silver aggregates formed in pure AgBr may be unstable, even when large enough to catalyze development. These aggregates readily decompose under the influence of deep electron traps introduced by sulfur sensitization. It is shown that adsorption of Ag_2S on the surface initiates an internal-to-surface redistribution of silver built up into the volume prior to the sensitization procedure. This redistribution should be distinguished from redistribution and decay processes following the exposure to long wavelength radiation where additional energy is introduced to the Ag/AgBr system. A long-range action of the sensitizer has been established consisting in induction (or speeding) of diffusion transfer of silver at a considerable distance from the surface. The model proposed assumes that Ag aggregates, termed quasistable, are in dynamic equilibrium with the conduction band thus supplying free electrons to deeper trapping sites. The data reported can be interpreted in favor of the Gurney-Mott model assuming particularly that Ag_2S provides deeper trapping levels than any others present in pure AgBr, whereupon Ag_2S specks operate as efficient concentration centers. A possibility of studying the function of a sensitizer under conditions where photoholes do not accompany the aggregation of silver is proposed. (68 refs.)

109775 Influence of chemical sensitization on photographic response: a computer modeling study. M.R.V.Sahyun (Central Res. Lab., 3M Center, St. Paul, MN, USA).
Photogr. Sci. & Eng. (USA), vol.27, no.4, p.171-7 (July-Aug. 1983).
A comprehensive computer model of latent formation in silver halide emulsion grains is attempted: size and effectiveness distributions of sulfide sensitivity specks, their dispersion among emulsion grains, and the process of latent image formation, according to the phase formation theory are all considered. Characteristic and DQE curves are calculated and presented for high-intensity exposure conditions. Results are related to conditions and parameters of chemical sensitization. Accordingly, directions of future, fruitful experimental investigations of the photographic process as well as the principal possibilities for its significant improvement, are considered. (53 refs.)

109776 Efficiency modulated sensitization. J.R.Harbour (Xerox Res. Centre of Canada, Mississauga, Ontario, Canada).
Photogr. Sci. & Eng. (USA), vol.27, no.4, p.178-81 (July-Aug. 1983).
ZnO particles surface modified through the synthetic deposition of Zn phthalocyanine exhibit a unique type of sensitization. With these particles, the normal photoactivity of ZnO, produced through excitation with 380 nm light can be modulated by coincident red light excitation adsorbed by the ZnPC. The ZnPC does not spectrally sensitize this ZnO photoactivity in the absence of the 380 nm irradiation. Using ESR spectroscopy, the author was able to monitor the photoinduced formation of the ZnPC cation radical and the $g=1.96$ ZnO signal associated with trapped conduction electrons. These ESR results corroborate a proposed mechanism for this sensitization in which a reduction of hole/electron recombination is mediated by the photo-excitation of ZnPC. (29 refs.)

109777 Spectral properties of flavins in hydrophilic matrices. K.Bystra, R.Drabent, L.Szubiskowska, B.Smyk (Inst. of Phys. & Food Chem., Acad. of Agriculture & Technol., Olsztyn, Poland).
Spectrosc. Lett. (USA), vol.16, no.7, p.513-30 (1983).
Absorption and emission properties of flavins (riboflavin 5-phosphate (FMN), riboflavin and 10-formylmethylisoalloxazine) in hydrophilic matrices have been studied. The results were discussed in terms of a possible change of the isoalloxazine nucleus geometry. The angles between absorption transiton moments and emission transition moment were estimated. It is suggested that FMN stabilized by PVA matrix can be treated as the energetically-well-isolated molecular system. (35 refs.)

109778 The effect of ammonia ions on the absorption and fluorescence of an oxazine dye. J.F.Giuliani, T.W.Barrett (Chem. Div., US Naval Res. Lab., Washington, DC, USA).
Spectrosc. Lett. (USA), vol.16, no.7, p.555-63 (1983).
The addition of ammonium hydroxide to a weakly acidic oxazine perchlorate dye produces a color change by means of a deprotonation mechanism in which the hydroxyl radical abstracts a loosely bound proton, leaving the positively charged ammonium cation to counter balance the perchlorate anion. This reaction produces significant absorption and fluorescence band shifts which can be accounted for by a semi-classical oscillator model predicting two dichroic electronic band systems associated with this dye. Peculiar wavelength excitation dependent fluorescence band shifts are attributed to overlapping triplet states simultaneously excited. (6 refs.)

109779 On the determination of emission quantum yields in turbid solid and liquid solutions. J.Bendig (Sektion Chem., Humboldt-Univ. zu Berlin, Berlin, Germany).
Z. Phys. Chem., Leipzig (Germany), vol.264, no.4, p.807-12 (1983). In German.
The known method of determination of fluorescence quantum yields does not apply to cases of turbid solid and liquid solutions, because of the light scattering. A new method is described, which is based on the measurement of a mixture of fluorophore and standard solutions. The necessary experimental conditions are given. The method is tested on the combination N-methylacridone/9,10-diphenylanthracene in ethanol at 77K. (14 refs.)

82.50E Photodissociation, photoionization as studied by luminescence and radiationless transitions

109780 Photoselection of conformational substrates and the hyposochromic photoproduct of rhodopsin. A.Cooper (Dept. of Chem., Glasgow Univ., Glasgow, Scotland).
Chem. Phys. Lett. (Netherlands), vol.99, no.4, p.305-9 (12 Aug. 1983).
Inhomogeneous broadening of visual pigment spectra may be due, in part, to the known dynamic conformational properties of protein molecules. As a consequence, the blue-shifted species formed by long-wavelength irradiation of rhodopsin at very low temperatures could be an artefact arising from pho-

toselection ('hole burning') of different conformational substates of the protein chromophore in the frozen matrix. Numerical simulation of this process mimics many of the observed spectral properties of hypsorhodopsin. (29 refs.)

82.55 RADIOCHEMISTRY

109781 The point of zero charge and adsorption properties of natural magnetite. S.K.Milonjic, M.M.Kopecni, Z.E.Ilic (Boris Kidric Inst. of Nuclear Sci.-Vinca, Beograd, Yugoslavia).
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.15-24 (1983).
The authors report the point of zero charge (pH_{zpc}) of natural magnetite and its adsorptive properties with regard to alkali metal ions. pH_{zpc} of freshly ground, untreated magnetite is 6.5, decreasing, after treatment with HCl, to the value of pH 3.8. This discrepancy might be explained as a consequence of possible structure changes on the magnetite surface. Adsorption properties of magnetite with respect to Li^+, Na^+ and K^+ ions in the concentration and pH ranges varying from 0.1 to 1.0 $mol.dm^{-3}$ and 6.5 to 10, respectively, were examined. For the used chloride media used, the adsorption sequence obtained is $Na^+ > K^+ > Li^+$. (37 refs.)

82.60 CHEMICAL THERMODYNAMICS

(see also 05.70 Thermodynamics)

109782 Partial molal volumes of some halobenzenes in carbon tetrachloride. F.Shahidi (Dept. of Chem. Engng. & Appl. Chem., Univ. of Toronto, Toronto, Ontario, Canada).
Can. J. Chem. (Canada), vol.61, no.7, p.1414-16 (July 1983).
The partial molal volumes at infinite dilution $\bar{V}^0$ for a number of halobenzenes are measured and related to their van der Waals volumes. Results indicate larger volume increments for halogen atoms in halobenzenes than those in alkyl halides. Possible explanations are forwarded. The effect of steric overcrowding in ortho-substituted benzenes on the $\bar{V}^0$ values are evaluated. (11 refs.)

109783 Diffusion with hydrolysis equilibria: transport coefficients of aqueous SO_2, NH_3 and Na_2CO_3. D.G.Leaist (Div. of Chem., Nat. Res. Council of Canada, Ottawa, Ontario, Canada).
Can. J. Chem. (Canada), vol.61, no.7, p.1494-9 (July 1983).
Practical equations are derived for estimating diffusion coefficients and Onsager transport coefficients of aqueous solutes subject to hydrolysis. The derivation is based on the Nernst-Hartley method which is extended to include chemical reaction of solute with solvent. The derived equations and existing mobility data are used to estimate transport coefficients of aqueous SO_2 (20°C), NH_3 (15°C) and Na_2CO_3 (25°C). In dilute solution where hydrolysis is extensive, rates of diffusion of SO_2 and NH_3 are increased by about 50% and 25%, respectively, relative to unhydrolyzed solute. Because of the carbonate-bicarbonate equilibrium, diffusion in aqueous Na_2CO_3 is a ternary process characterized by coupled transport of NaOH. In dilute solution the NaOH flux may exceed the flux of Na_2CO_3. (44 refs.)

109784 A systematic study on volumetric interactions of cyclohexanone with various aliphatic hydrocarbons. B.Chawla, R.Parkash, S.K.Suri (Dept. of Chem., Indian Inst. of Technol., New Delhi, India).
Can. J. Chem. (Canada), vol.61, no.7, p.1647-50 (July 1983).
Excess volumes of mixing, V^E, for binary mixtures of cyclohexanone with *n*-hexane, *n*-heptane, *n*-octane, *n*-nonane, *n*-decane, *n*-dodecane, *n*-tetradecane and *n*-hexadecane at 25°C were determined from the precise and accurate experimental density data. The sign and magnitude of $\bar{V}^E$ were discussed in terms of the strength of the unlike interactions present in the binary mixtures. Excess volumes of mixing of equimolar concentration (${V_{0.5}}^E$) were also obtained. Attempts were made to interpret ${V_{0.5}}^E$ in terms of the size and polarity of the constituent molecule. The two effects could not be separated, but a good linear relation between ${V_{0.5}}^E$ and the solubility parameter was found. (13 refs.)

109785 Heat integration of distillation columns into overall processes. B.Linnhoff (Dept. of Chem. Engng., Univ. of Manchester Inst. of Sci & Technol., (UMIST),,England). Manchester, H.Dunford, R.Smith.
Chem. Eng. Sci. (GB), vol.38, no.8, p.1175-88 (1983).
The authors put the design of individual distillation columns into context with the heat integration for the overall process. Good integration between distillation and the overall process can result in columns operating at effective zero utility cost. Some of the traditionally well-known schemes may in certain circumstances turn out counter-productive. They can prevent good integration and therefore eliminate the change of obtaining zero utility costs. Generally, the authors define good integration as a column not crossing the heat recovery pinch of the process and either the reboiler or the condenser being integrated with the process. If these criteria can be met, energy costs for distillation can effectively be zero. (16 refs.)

109786 On the binding of ligands to macromolecules: an accurate procedure. G.Baldini, M.Succi, G.Varani (Dipartimento di Fisica, Univ. di Milano, Milano, Italy).
Nuovo Cimento D (Italy), vol.2D, ser.1, no.4, p.1065-74 (July-Aug. 1983).
The determination of equilibrium constants, seen, e.g., in the usual scatchard plots, may be highly inaccurate because generally the values of the bound-ligand response are known with large uncertainty. A common cause of this inaccuracy stems from the use of samples that contain small amounts of free ligand, hardly avoided, or from equilibrium dialysis which is generally affected by the Donnan effect, dye losses, etc. From an analysis of this problem a simple procedure is derived, so that, in spite of the above drawbacks, the equilibrium parameters can be obtained with better precision. (5 refs.)

109787 The relative thermal value of tomorrow's fuels. H.C.Hottel (Dept. of Chem. Engng., MIT, Cambridge, MA, USA).
Ind. & Eng. Chem., Fundam. (USA), vol.22, no.3, p.271-6 (Aug. 1983).
An examination of the enthalpy-temperature relation for the products of combustion with air of twenty representative gas, liquid, and solid fuels showed that if the enthalpy is normalized by division by its value at a standard temperature—1800K was chosen—the so-normalized enthalpy-temperature function H^* (T) is, with accuracy adequate for engineering use, the same for all fuels studied. In consequence the T-Q path of furnace gases from a superior fuel may be exactly matched with an inferior fuel if additional input enthalpy is made available. The H^* concept permits quantitative formulation of RTV, relative thermal value, the value for use in furnaces of a Btu in a subject fuel compared to its value in a standard superior fuel. The concept also permits limited modeling of furnace performance of good fuels with poor ones, using a fuel-fired air preheater. RTV shows that methane is thermally inferior to syngas. (7 refs.)

109788 Saturated vapor pressure and heat of formation of As_4S_4. A.S.Pashinkin, A.A.Izergin, R.A.Amirov, A.S.Alikhanyan, A.V.Steblevskii (Moscow Electronics Inst., Moscow, USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1056-9 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.L253-6 (Aug. 1982).
The vapour pressure of crystalline arsenic tetrasulfide was measured by the Knudsen method with continuous recording of the change in the weight of the effusion chamber. The equilibrium of the dissociation $As_4S_4 \rightleftarrows As_4(g) + 2S_2(g)$ was investigated by a mass spectrometric method, using a double effusion chamber. The heat of sublimation of As_4S_4 and the heat of its formation in the crystalline and gaseous states were calculated according to the data obtained (under standard conditions). (10 refs.)

109789 Enthalpy of formation of rubidium vanadates. M.Ya.Khodos, V.N.Krasil'nikov, A.A.Fotiev (Inst. of Chem., Acad. of Sci., USSR).
Inorg. Mater. (USA), vol.18, no.8, p.1140-2 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1346-8 (Aug. 1982).
Five rubidium vanadates—Rb_3VO_4, $Rb_4V_2O_7$, $RbVO_3$, $Rb_3V_5O_{14}$, $Rb_2V_6O_{16}$—exist in the subsolidus region of the system Rb_2O-V_2O_5. The values of the change in the standard enthalpies of formation of the vanadates $Rb_4V_2O_7$, $RbVO_3$, $Rb_3V_5O_{14}$, $Rb_2V_6O_{16}$ were determined by the method of calorimetry of the heats of solution. The standard enthalpy of formation of rubidium orthovanadate was estimated. (8 refs.)

109790 Neutron diffraction study of cubic ice nucleation in a porous silica network. D.C.Steytler, J.C.Dore (Phys. Lab., Univ. of Kent, Canterbury, England), C.J.Wright.
J. Phys. Chem. (USA), vol.87, no.14, p.2458-9 (7 July 1983).
Nucleation of supercooled water (D_2O) contained in the porous silica, Spherisorb S20W, has been studied by neutron diffraction. The onset of freezing occurred at −13°C giving a diffraction pattern characteristic of the metastable cubic form of ice I (ice I_c) containing a small amount of the more stable hexagonal polymorph (ice I_h). In addition to these crystalline phases there is also evidence of a more disordered structure indicating the presence of a considerable proportion of unfrozen water. (17 refs.)

109791 Search for a simplified procedure for the evaluation of the Gibbs free energy of hydrogen-bond formation. M.M.Szczesniak (Inst. of Chem., Univ. of Wroclaw, Wroclaw, Poland), P.Hobza.
J. Phys. Chem. (USA), vol.87, no.14, p.2608-14 (7 July 1983).
An attempt is made to correlate the theoretical stabilization energies of hydrogen-bonded complexes with theoretical vibrational frequencies, the change of zero-point energy, the vibrational part of the temperature dependence of the enthalpy change, and the vibrational part of the entropy change, within a set of 16 hydrogen-bonded complexes. The correlation found between the stabilization energy and the sum of terms depending on vibrational frequencies enables one to estimate the ΔG of formation of hydrogen-bonded complexes. (34 refs.)

109792 Transient effects on the droplet-formation barrier and the nucleation rate in deeply supersaturated metastable phases. H.Furukawa (Dept. of Phys. Sci., Yamaguchi Univ., Yamaguchi, Japan).
Phys. Rev. A (USA), vol.28, no.3, p.1729-37 (Sept. 1983).
Assuming that the nucleation occurs in a small region with the volume of the order $(Dt)^{3/2}$, where D is the diffusion constant and t is the time passing after a quench, the author finds, that the droplet-formation barrier undergoes a transition from an infinitely large value to a finite value indicating the existence of the onset of the nucleation reaction. This finite value of the droplet-formation barrier is smaller in deeply supersaturated phases than the value required for the stabilization of the supersaturated phase, i.e. $\sim 60k_BT - 70k_BT$. Thus the cloudiness should occur just after the droplet-formation barrier has undergone the transition. For a deeply supersatured phase the locus of the cloud point is described by $y_1 \propto \varepsilon^{-\phi} {t_1}^{-3/8}$, where $y_1 \propto \rho/\Delta\rho$ and $T_c(1-\varepsilon)$ are a reduced density (with $\Delta\rho$ being the coexistence curve) measured from the coexistence state, and the temperature of supersaturated phase with T_c being the critical temperature, respectively. t_1 is the observation time after a quench. The exponent ϕ is found to be 0.70 for the liquid and 0.47 for the kinetic Ising-spin system. At low temperatures or for large t_1, the cloud point is given by the traditional one. The comparisons of the present result with experimental data are presented. (18 refs.)

109793 Thermochemistry of the cubic and hexagonal lithium tungsten bronze phases Li_xWO_3. P.G.Dickens, S.A.Kay (Inorganic Chem. Lab., Univ. of Oxford, Oxford, England).
Solid State Ionics (Netherlands), vol.8, no.4, p.291-5 (July 1983).
The enthalpies of formation of hexagonal WO_3, hexagonal and cubic Li_xWO_3 have been determined by solution calorimetry. The ambient-temperature materials h-$Li_{0.44}WO_3$ and c-Li_xWO_3 (x=0.51, 0.71) were prepared by *n*-butyl lithiation in hexane. The thermochemistries of the lithium insertion compounds were examined and related to structural features. (21 refs.)

109794 Analyses of G^E data for binary systems in terms of generalized quasi-lattice theory. M.Diaz Pena, A.Crespo Colin, A.Compostizo, I.Escudero (Dept. de Quimica Fisica, Facultad de Quimicas, Univ. Complutense, Madrid, Spain).
Z. Phys. Chem., Leipzig (Germany), vol.264, no.4, p.699-704 (1983). In German.
Experimental data on the excess Gibbs free energy for binary mixtures consisting of methylcyclohexane, cyclohexane or benzene with either chlorobenzene, fluorbenzene or thiophene were interpreted on the basis of the lattice model. Five different types of interaction were considered. Each molecule has been assigned a given number of sites in a lattice whose coordination number was four. The assignment of a site number for each molecule is based on the assumption that benzene occupies four sites and is used as a reference. Interaction energies determined for each contact type based on data on the systems were consistent for all of them. (12 refs.)

82.65 SURFACE PROCESSES

109795 The adsorption of methanol on Ag(111) and its reaction with preadsorbed oxygen. T.E.Felter, W.H.Weinberg (Div. of Chem. & Chem. Engng., California Inst. of Technol., Pasadena, CA, USA), G.Ya.Lastushkina, P.A.Zhdan, G.K.Boreskov, J.Hrbek.
Appl. Surf. Sci. (Netherlands), vol.16, no.3-4, p.351-64 (July-Aug. 1983).
The adsorption and oxidation of methanol on Ag(111) has been studied by photoelectron spectroscopy. He II ultraviolet photoelectron spectroscopy (UPS) has been employed for adsorbed monolayers and condensed multilayers of methanol on the surface at 95K, and relatively small shifts are found. X-ray photoelectron spectroscopy (XPS) was also employed and shows that for thick multilayers an enhanced intensity for the carbon 1s compared to the oxygen 1s occurs which can be explained by simple considerations of the escape depth. Larger coverages of surface intermediates were observed with XPS when active oxygen was initially on the surface. The intermediates include formaldehyde, methoxide, and possibly hemiacetyl alcoholate. The observation of formaldehyde implies a desorption limited formation step contrary to earlier published work. The kinetics of the oxidation reaction can be described by a simple Langmuir-Hinshelwood mechanism with rate parameters $\nu=10^{-9}$ cm^2 and $E=8.7$ kcal/mol. (25 refs.)

109796 X-ray photoemission spectroscopy of potassium promoted Fe and Pt surfaces after H_2 reduction and CO/H_2 reaction. H.P.Bonzel, G.Broden, H.J.Krebs (Inst. fur Grenzflachenforschung und Vakuumphys., KFA Julich, Julich, Germany).
Appl. Surf. Sci. (Netherlands), vol.16, no.3-4, p.373-94 (July-Aug. 1983).
Samples of Fe and Pt were cleaned in ultra-high vacuum (UHV) and then moved out to atmosphere to be covered with unknown amounts of KNO_2, K_2CO_3 and KOH in aqueous solution. After subsequent evaporation of water and heating to 470 and 690K the adsorbates were characterized by X-ray photoemission spectroscopy (XPS) and Auger electron spectroscopy. They were then reduced in 1 bar flowing H_2 at 570K for 5 min. XPS of the O(1s) core level provides evidence for the formation of adsorbed KOH in all cases. KOH is believed to be present in the form of K^+ and OH^-. The K coverage is estimated to be about one monolayer or higher. The K-promoted Fe samples were also subjected to a CO/H_2 mixture at 570K to produce hydrocarbons. XPD of the carbon layer deposited during this reaction showed C(1s) peaks at 289.0, 285.4 and 283.7 eV indicative of carbonate, CO and CH_x-type carbon, respectively. The high coverage of CO for K-promoted Fe is in accord with an increase in the adsorption energy of CO. The implications of these results of the hydrogenation of CO on K-promoted Fe are discussed. (32 refs.)

109797 Inelastic electron tunneling spectroscopic studies of adsorption of simulated epoxy resin. S.Affrossman (Dept. of Pure & Appl. Chem., Univ. of Strathclyde, Glasgow, Scotland), N.M.D.Brown, R.A.Pethrick, V.K.Sharma, R.J.Turner.
Appl. Surf. Sci. (Netherlands), vol.16, no.3-4, p.469-73 (July-Aug. 1983).
A model compound has been synthesised to simulate an amine cured epoxy resin. IET spectra of the compound adsorbed on a junction from solution suggest that bonding to the oxide occurs by chemisorption. Possible modes of bonding are discussed with reference to IETS results from related compounds. (18 refs.)

109798 Asymptotic analysis of single pore gas-solid reactions. K.Shankar, Y.C.Yortsos (Dept. of Chem. Engng., Univ. of Southern California, Los Angeles, CA, USA).
Chem. Eng. Sci. (GB), vol.38, no.8, p.1159-65 (1983).
The single-pore model for gas-solid reactions is used to develop exact, closed-form solutions for the concentration, pore radius and conversion profiles in a long, narrow pore for both cylindrical and slab geometries. For relatively large values of the Thiele modulus, the solutions portray the asymptotic behavior of the reaction scheme in a finite pore. The cases of incomplete conversion associated with pore closure at low initial porosities and complete conversion associated with a moving reaction zone at high initial porosities are analyzed. It is shown that the asymptotic results provide very accurate estimates of the overall conversion in applications involving large pore diffusional resistance or fast reactions. The sensitivity of the conversion to various physicochemical parameters is also examined. (14 refs.)

109799 Crystallisation and topochemical processes occurring on the surfaces of crystals of phosphates. E.A.Prodan, V.V.Samuskevich, T.N.Galkova, S.I.Pytlev (Inst. of General & Inorganic Chem., Acad. of Sci., Belorussian SSR).
Inorg. Mater. (USA), vol.18, no.8, p.1124-7 (Aug. 1982). Translation of: *Izv. Akad. Nauk SSSR Neorg. Mater.*, vol.18, no.8, p.1329-32 (Aug. 1982).
Describes the characteristic forms of localisation of topochemical reactions occurring on the surfaces of $Na_3P_3O_9.6H_2O$ crystals (dehydration) and $MnHPO_4.3H_2O$ crystals (dehydration, disproportionation, and ammonisation). They show that the parameters of the reaction depend on the growth conditions and face development of the crystal, and that the rate of crystallisation of the product is related to the features of the reaction and its characteristic localisation. (7 refs.)

109800 The effect of surface diffusion on surface reaction rates. R.I.Cukier (Dept. of Chem., Michigan State Univ., East Lansing, MI, USA).
J. Chem. Phys. (USA), vol.79, no.5, p.2430-5 (1 Sept. 1983).
The author presents a simple model to explore the role of surface diffusion on the rate of reaction between a surface diffusing species and a set of fixed randomly distributed reactive sites. A Langmuir adsorption/desorption term is used to describe the influence of the bulk phase on the surface. Reaction is modeled by a fast, with respect to surface diffusion, absorption on the perimeters of the reactive sites. A general effective medium theory is formulated for this model and solved approximately for the rate k_f and diffusion coefficient D, which characterize the transport of the reactive density on a scale large compared with intersite dimensions. The author finds that surface diffusion can be an important contributing factor to the rate of reaction. In particular, when surface diffusion is rapid relative to the Langmuir adsorption/desorption rate, the reaction rate increases strongly with increasing reactive site surface concentration relative to its value for low surface site concentration. (12 refs.)

109801 Chemisorption of oxygen at Ag(110) surfaces and its role in adsorbate activation. [Photoelectron spectra observations]. Chak-tong Au, S.Singh-Boparai, M.W.Roberts (Dept. of Chem., Univ. Coll. Cardiff, Cardiff, Wales), R.W.Joyner.
J. Chem. Soc. Faraday Trans. I (GB), vol.79, pt.8, p.1779-91 (Aug. 1983).
Oxygen has been shown by X-ray photoelectron spectroscopy (XPS) and ultraviolet photoelectron spectroscopy (UPS) studies to be adsorbed both molecularly and dissociatively at an Ag(110) surface at 80K. Chemisorbed chlorine inhibits the formation of the dissociative state. The interaction of water vapour with Ag(110) is influenced strongly, even at 80K, by the presence of O^{2-} (a). The formation of surface hydroxyls and hydrogen-bonded water clusters is discussed. Surface oxygen undergoes a chemisorptive replacement reaction with HCl (g) below 175K. At 473K there is strong evidence from both XPS and UPS for three states of oxygen; one of these is a strongly chemisorbed dioxygen species, while the other two involve dissociated oxygen one of which is sub-surface. Comparisons are made between the core and valence-level spectra observed with the Ag(110)-Cl+O_2 system and those obtained with an industrial silver catalyst known to be active in ethylene epoxidation. (19 refs.)

109802 Error simulation experiments. The virial equation in the absorption of isobutene on Aerosil. J.Cortes, H.Puschmann, E.Valencia (Facultad de Ciencias Fisicas y Matematicas, Univ. de Chile, Santiago, Chile).
J. Chem. Soc. Faraday Trans. I (GB), vol.79, pt.8, p.1833-42 (Aug. 1983).
The adsorption of 2-methylprop-1-ene on Aerosil has been investigated as a prototype system for studying the precision with which the coefficients of the virial adsorption isotherm can be determined from experimental data. An experiment simulation method is developed to calculate the error produced in the determination of parameters for a model applied to an experimental system. (11 refs.)

109803 Characterization of the surfaces of MgO-ZnO solid solutions by CO and H_2 adsorption at room temperature. G.Ghiotti, F.Boccuzzi (Istituto di Chimica Fisica, Univ. di Torino, Torino, Italy).
J. Chem. Soc. Faraday Trans. I (GB), vol.79, pt.8, p.1843-56 (Aug. 1983).
Solid solutions of ZnO and MgO with larger surface areas than those previously reported in the literature have been prepared and their formation tested by ultraviolet-visible reflectance spectroscopy. The surface chemistry of CO and H_2 (or D_2) interactions has been studied by infrared spectroscopy. Large differences with respect to the surface chemistry of the pure oxides have been found. CO is mainly adsorbed on MgO couples as oxidized carboxylate-type species which are stable up to 373K and then transformed into carbonate-type species. H_2 is mainly chemisorbed by heterolytic dissociation on three different Zn-O couples. (31 refs.)

109804 Formation of surface states on strontium oxide powders. [Photoluminescence observations]. S.Coluccia (Chem. Div., AERE, Harwell, England), A.J.Tench.
J. Chem. Soc. Faraday Trans. I (GB), vol.79, pt.8, p.1881-9 (Aug. 1983).
A detailed study of the formation of the oxide surface has been carried out by following the evolution of the various components of the photoluminescence spectra at successive stages of the thermal pretreatment of the samples. Different sets of ions in low coordination on the surface are correlated to specific bands in the emission as well as in the excitation spectra. At 300K, the results are consistent with energy transfer from the surface sites in high coordination to those in low coordination. (16 refs.)

109805 Comment on graphite intercalated with H_2SO_4. L.B.Ebert (Corporate Res.-Sci. Labs., Exxon Res. & Engng. Co., Linden, NJ, USA), E.H.Appelman.
Phys. Rev. B (USA), vol.28, no.3, p.1637-8 (1 Aug. 1983).
Salaneck, Brucker, Fischer, and Metrot (Phys. Rev. B 24, 5037, 1981) have stated that X-ray-photoelectron spectroscopic data indicate that the intercalant of the graphite-sulfuric-acid system consists of species containing a variety of $S_nO_{4n}{}^{2-}$ ions. The authors question the evidence for these peroxy sulfate species, since $C_{17}{}^+$ can be formed at potentials 0.23 to 0.38 V below that necessary to make $S_2O_8{}^{2-}$. The reaction of the chemically similar SO_4F^- species with graphite yields a product which does not contain SO_4F^-, suggesting that strong chemical oxidants will not be stable with respect to graphite. (20 refs.)

109806 Reply to 'Comment on graphite intercalated with H_2SO_4'. W.R.Salaneck, C.F.Brucker (Xerox Webster Res. Center, Webster, NY, USA), J.E.Fischer, A.Metrot.
Phys. Rev. B (USA), vol.28, no.3, p.1639 (1 Aug. 1983).
For comment see ibid., vol.28, no.3, p.1637 (1983). The authors defend their proposal that peroxidation can account for most of the charge accumulated between $C_{27}{}^+$ and $C_{12}{}^+$ in the graphite-bisulfate intercalation system. (4 refs.)

109807 Surface reactions and excitations. A.Howie (Cavendish Lab., Univ. of Cambridge, Cambridge, England).
Ultramicroscopy (Netherlands), vol.11, no.2-3, p.141-8 (1983). (Surface Imaging and Analysis with High Spatial Resolution, Wickenburg Inn, AZ, USA, 12-15 Jan. 1983).
Observations are presented of the growth of oxide nuclei on Al and Cu which illustrate the power of clean surface and RHEED techniques when combined with electron microscopy. Inelastic scattering and image potential effects in the RHEED and glancing angle microscopy situation are estimated using classical dielectric excitation theory. Attention is drawn to resonance effects which may occur in the surface excitations on small particles. Possible Bloch wave transitions corresponding to novel inelastic scattering processes inside the crystal and which may be significant in the glancing angle case are described. (22 refs.)

109808 Reactivity and optical properties of silicate glass surfaces. H.H.Dunken (Friedrich-Schiller-Univ. Jena, Jena, Germany).
Wiss. Z. Friedrich-Schiller-Univ. Jena, Math. Naturwiss. Reihe (Germany), vol.32, no.2-3, p.263-83 (1983). In German. (Otto-Schott-Colloquium on the State of Optical Glass Research 1982, Jena, Germany, 1982).
The chemical durability of silicate glasses is investigated by means of selected experimental methods. The reactivity experimental data are discussed on the basis of quantumchemical cluster-calculations. The same quantumchemical model is used to calculate the optical properties, especially oscillator strengths and dispersion. The influence of structure and composition on the reactivity and optical properties of the glasses is also discussed. (30 refs.)

82.70 DISPERSE SYSTEMS

(for flow behaviour, see 47.55K)

109809 Dielectric properties of sulfopropyl Sephadex gel beads dispersed in aqueous solutions. A.Ishikawa, T.Hanai, N.Koizumi (Inst. for Chem. Res., Kyoto Univ., Kyoto-Fu, Japan).
Jpn. J. Appl. Phys. Part 1 (Japan), vol.22, no.6, p.942-7 (June 1983).
Dielectric measurements were carried out on beds consisting of beads of the ion-exchange resin sulfopropyl Sephadex of the strong-acid type over the frequency range 30 Hz to 130 MHz. Striking dielectric relaxations were observed with dielectric increments of 10^2-10^3 in dielectric units and relaxation frequencies of 10 MHz. The relative permittivities and electrical conductivities of ion-exchange resins with different ionic forms were evaluated by the method proposed in recent investigations on the basis of theories of interfacial polarization. The values of the relative permittivities thus determined were unchanged irrespective of the ionic form and were smaller than the value for water. The values of the electrical conductivities changed with the ionic species of the counter ions. (29 refs.)

109810 Method for determining the effectiveness of dispersants for magnetic oxide. R.L.Bradshaw, S.J.Falcone, R.L.Price, A.Simonetti (IBM Corp., Armonk, NY, USA).
IBM Tech. Disclosure Bull. (USA), vol.26, no.2, p.447-8 (July 1983).
The dispersant and magnetic oxide particles are mixed and a particle size analysis is used to assess the effectiveness of the dispersant. This method is particularly useful to classify the ability of dispersants to properly disperse chromium dioxide particles in a polymer/solvent coating link, which coating ink is used to coat a substrate, in the process of manufacturing magnetic recording media. (no refs.)

109811 Diffusion-controlled flocculation: the effects of attractive and repulsive interactions. P.Meakin (Central Res. & Dev. Dept., E.I. du Pont de Nemours & Co. Inc., Wilmington, DE, USA).
J. Chem. Phys. (USA), vol.79, no.5, p.2426-9 (1 Sept. 1983).
A Monte Carlo computer model has been used to investigate the effects of repulsive interactions (sticking probabilities less than 1.0) and attractive interactions (particle capture) on diffusion-controlled aggregation processes. The author finds that particle capture leads to clusters with lower densities, whereas small sticking probabilities lead to higher density clusters. The radii of gyration (R_g) of clusters grown under diffusion-controlled conditions can be related to the number of particles in the cluster by $R_g = AN^{\beta}$. Despite the considerable difference in densities, the author finds that clusters grown with small sticking probabilities or large capture radii give quite similar values for the radius of gyration exponent (β) in the limit of large cluster sizes. The model details are expressed in the radius of gyration amplitude factor A. The results reported in the paper were obtained using a two-demensional nonlattice model. The author expects that similar results will be found in three-dimensional simulations. (10 refs.)

109812 Analysis of small angle neutron scattering spectra from polydisperse interacting colloids. M.Kotlarchyk, Sow-Hsin Chen (Dept. of Nuclear Engng., MIT, Cambridge, MA, USA).
J. Chem. Phys. (USA), vol.79, no.5, p.2461-9 (1 Sept. 1983).
In the paper, the authors outline a simple procedure for analyzing small angle neutron scattering (SANS) spectra from interacting colloids containing a continuous distribution of particle sizes. In particular, the effects of polydispersity on the apparent interparticle structure factor S′(Q) observed by SANS is investigated. They find that the oscillations in S′(Q) are significantly damped in comparison to those of the true structure factor S(Q). When their procedure is extended to the analysis of SANS spectra from nonspherical particles, they find that orientational averaging affects S′(Q) in a qualitatively similar way. The applicability of the procedure to the analysis of real data is demonstrated with spectra taken from water-in-oil microemulsions, ionic micelles, and interacting protein. (24 refs.)

109813 Phase composition of aqueous/hydrocarbon systems containing organic salts, alcohol, and sodium chloride. P.C.Ho, T.M.Bender (Chem. Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA).
J. Phys. Chem. (USA), vol.87, no.14, p.2614-20 (7 July 1983).
The phase compositions of five-component systems containing *n*-octane, water, 1-butanol, sodium chloride, and one of two low-equivalent-weight organic salts (protosurfactants) have been analyzed. The organic salts are sodium 2,5-diisopropylbenzenesulfonate or sodium 3,5-diisopropylsalicylate, both of which have six alkyl carbons on side chains of the benzene ring. The similarities earlier observed in phase behaviour of protosurfactant systems and surfactant systems are extended in these results. The distribution of organic salts between phases with changes in composition follows the trends known for surfactants. (23 refs.)

109814 Determination of interparticle structure factors in ionic micellar solutions by small angle neutron scattering. D.Bendedouch, Sow-Hsin Chen (Dept. of Nuclear Engng., MIT, Cambridge, MA, USA).
J. Phys. Chem. (USA), vol.87, no.14, p.2621-8 (7 July 1983).
A series of small-angle neutron-scattering (SANS) intensity spectra measurements were carried out on aqueous micellar solutions of ionic detergent lithium dodecyl sulfate (LDS). A systematic study of the system was conducted as a function of both detergent concentration, from 0.008 to 1.107 M, and salt (LiCl) concentration, from 0.0 M, at around 37°C. The data show that LDS micelles stay 'small' within this range of solution conditions, and therefore analysis can be made regarding the micelles as approximately monodisperse macroions suspended in a solution of given ionic strength. Analysis is made by using a mean spherical approximation for a model charged hard-sphere system to compute the interparticle structure factor, and a uniform prolate spheroidal structure for the micellar core to model the intraparticle structure factor. (24 refs.)

109815 Electrostatic curvature contributions to interfacial tension of micellar and microemulsion phases. D.J.Mitchell, B.W.Ninham (Dept. of Appl. Math., Australian Nat. Univ., Canberra, Australia).
J. Phys. Chem. (USA), vol.87, no.16, p.2996-8 (4 Aug. 1983).
Analytic expressions are derived for the interfacial tension of ionic micellar and microemulsion systems. The theory assumes validity of the nonlinear equation. Comparison with data for sodium dodecyl sulfate (SDS) provides strong support for earlier theories of self-assembly of ionic surfactants. (21 refs.)

109816 Solutions and critical times for the polydisperse coagulation equation when $a(x,y)=A+B(x+y)+Cxy$. J.L.Spouge (Trinity Coll., Oxford, England).
J. Phys. A (GB), vol.16, no.13, p.3127-32 (11 Sept. 1983).
Gives solutions of the polydisperse Smoluchowski coagulation equation $\partial f(x,t)/\partial t = {}^1/_2\int_0^x f(y,t)f(x-y,t)a(y,x-y)\mathrm{d}y - f(x,t)\int_0^\infty f(y,t)a(x,y)\mathrm{d}y$, $f(x,0)=g(x)$ for arbitrary $g(x)$ when the coagulation kernel $a(x,y)=A+B(x+y)+Cxy$. The solutions are given as recursions and infinite series and are practical for computation. For the given kernels the author also gives the gelation times t_g at which $M_2(t)=\int_0^\infty x^2 f(x,t)\mathrm{d}x$ becomes infinite. (13 refs.)

109817 The effect of Brownian diffusion on shear-induced coagulation of colloidal dispersions. D.L.Feke, W.R.Schowalter (Dept. of Chem. Engng., Princeton Univ., Princeton, NJ, USA).
J. Fluid Mech. (GB), vol.133, p.17-35 (Aug. 1983).
The effect of a small amount of Brownian diffusion on shear-induced coagulation of spherical particles has been calculated. This has been accomplished by considering the binary collision process between a test sphere and identical spheres interacting with the test sphere through induced-dipole attraction, electrostatic repulsion and hydrodynamically induced forces. The effect of diffusion is found by means of an expansion in inverse Peclet number. Specific calculations were performed for uniaxial extension and for laminar shear flow. It is found that Brownian diffusion, the effect of which is nonlinearly coupled with flow type and strength, can act to increase or decrease the coagulation rate. (14 refs.)

109818 Kinetics of the aggregation of a dilute, finely disperse system at low shear velocities. Yu.A.Buevich, K.S.Kuvalkin (Ural'sk State Univ., Sverdlovsk, USSR).
J. Eng. Phys. (USA), vol.43, no.4, p.1083-90 (Oct. 1982). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.43, no.4, p.565-73 (Oct. 1982). [received: Sept. 1983]
The formation of doublets of spherical particles in a shear stream due to Brownian motion is considered with allowance for their hydrodynamic interaction and the breakup of doublets with a low binding energy. (16 refs.)

109819 Multiple Rayleigh-Gans-Debye scattering in colloidal systems—general theory and static light scattering. J.K.G.Dhont (Van't Hoff Lab., voor Fys. en Colloidchem., Rijksuniv. Utrecht, Utrecht, Netherlands).
Physica A (Netherlands), vol.120A, no.1-2, p.238-62 (1983).
For small differences in the refractive index between the Brownian particles and the solvent, the total scattered field strength may be represented as a series of single-, double- and higher-order scattered field strengths. Equations for these *n*th-order field strengths, scattered from a collection of Brownian particles with fixed orientations and positions are derived. Scattered intensities (up to second order) from a colloidal system containing identical spherical particles are then obtained by ensemble averaging over position coordinates, taking interaction into account. The resulting formulas are relatively simple, and can be used for routine correction of scattering data for double scattering. The geometry of the scattering system plays an important role here.

Experiments on colloidal solutions containing latex and silica particles are performed, testing the theory and the interactive correction method for double scattering. The author used cylindrical cuvettes with rectangular incident and detected beams of radiation. The agreement between experiment and theory is good, yielding a routine correction procedure for double scattering, up to double scattering percentages of about 50%. (11 refs.)

109820 Estimation of the co-ordination number in a multi-component mixture of spheres. M.Suzuki, T.Oshima (Dept. of Chem. Engng., Himeji Inst. of Technol., Himeji, Japan).
Powder Technol. (Switzerland), vol.35, no.2, p.159-66 (July-Aug. 1983).
A simple model of a 2-component mixture of spherical- or disk-type particles was proposed for estimating the co-ordination number, which is the number of contact points on a particle. To verify the validity of the model, the co-ordination numbers calculated from the model were compared with those obtained from the computer simulation of a 2-component mixture and there was fairly good agreement between the two sets of data. An extension of the model was made to calculate the effect of multi-component spherical particles on the co-ordination number. The model gives a good approximation to the existing experimental data for 4- and 5-component mixtures. (6 refs.)

82.80 CHEMICAL ANALYSIS AND RELATED PHYSICAL METHODS OF ANALYSIS

109821 Auger electron spectroscopy as a tool in an industrial laboratory. P.-E.Nilsson-Jatko, S.Sehlstedt, L.Unneberg.
ASEA J. (Sweden), vol.56, no.1, p.26-31 (1983).
Some examples of the areas within ASEA where this technique has been successfully applied are described. The analytical technique makes it possible to determine the chemical composition of extremely thin surface layers. The analysis depth is of the order of two to three atomic layers, that is about 10 Å. (no refs.)

109822 Influence on microwave device performance of n-GaAs surface chemical composition deviation induced by mask layer growth. Chen Keming, Wang Sen, Chen Weide, Fang Puming (Inst. of Semiconductors, Acad. Sinica, Beijing, China).
Chin. J. Semicond. (China), vol.4, no.4, p.334-9 (July 1983). In Chinese.
The influence of (100) n-GaAs surface chemical composition deviation on characteristics of Schottky barrier and ohmic contact is investigated using ϕ550 AES/ESCA system with ion sputtering. The deviation is formed while SiO_2 deposited at different temperatures on n-GaAs is used as a mask. On the basis of the above studies it is suggested that the usual SiO_2 deposition process is composed of two physical processes, i.e. primarily the SiO_2 deposition and the arsenic volatilization followed by oxygen from As-O bonds transfer to Ga to form additional Ga-O bonds. The answer is given to why the performance of a 3 mm mixer using SiO_2 deposited at 400°C as mask is superior to that of a 4 mm mixer using SiO_2 deposited at 700°C, and it is shown that unsatisfactory performances of the latter are due to the β-Ga_2O_3 still existing at Ni/n-GaAs interfaces and leading to more defects. (7 refs.)

109823 Entropy changes during an ideal gas chromatographic separation. M.Jaffar (Dept. of Chem., Quaid-i-Azam Univ., Islamabad, Pakistan).
Arabian J. Sci. & Eng. (GB), vol.8, no.2, p.141-3 (April 1983).
The present investigation attempts to put forward a modified quantitative approach to study the isentropic/nonisentropic gas liquid chromatography (GLC) separations, taking into account the entropy changes as a function of concentration profile variations arising from changes in the carrier gas flow in the retentive regions of an ideal column. In addition, the present work offers a mathematical analysis for estimating thermodynamic properties of multi-component mixtures through GLC parameters. (6 refs.)

109824 An activation method to determine the isotopic ratio of ^{6}Li/^{7}Li in lithium compounds. J.Asher, M.T.Swinhoe (Nuclear Phys. Div., AERE, Harwell, England).
Nucl. Instrum. & Methods Phys. Res. (Netherlands), vol.213, no.2-3, p.503-6 (1 Aug. 1983).
A method to determine the isotopic composition of lithium compounds has been developed, with two variations. In one, the activity of ^{7}Be, produced when the sample is bombarded with 4.8 MeV deuterons [via the ^{6}Li(d,n) reaction], is compared with the activity produced in a sample of the same compound with a known ^{6}Li/^{7}Li ratio. In the second, a cross-comparison is made between samples of different composition for both deuteron- (^{6}Li activation) and proton-(^{7}Li activation) induced activities of ^{7}Be, giving ^{6}Li/^{7}Li ratio measurements independent of calibration. The method works well for compounds not containing hydrogen; a lower limit on the sensitivity to ^{6}Li content was found because of residual hydrogen in the compounds investigated. (6 refs.)

109825 The determination of trace inorganic contaminants in polyimides. E.Sacher (Dept. of Engng. Phys., Ecole Polytech., Montreal, Quebec, Canada).
IEEE Trans. Electr. Insul. (USA), vol.EL-18, no.4, p.369-73 (Aug. 1983).
Several techniques capable of measuring inorganic contaminants in the PPM to PPB range have been used to analyze both polyimides and their aqueous extracts for mobile ions. The techniques include plasma spectroscopy, ion chromatography and neutron activation analysis. Their combination has shown that the most hostile mobile ions present are alkali metal ions. While halide ions are present in bulk polymer they are not mobile. The techniques, their limitations, and possible contamination sources are discussed. (18 refs.)

109826 Spectrographic analysis of semiconductor silicon and germanium with a hollow-cathode discharge. N.K.Rudnevskii, D.E.Maksimov, A.N.Tumanova, T.M.Shabanova.
J. Appl. Spectrosc. (USA), vol.37, no.5, p.1219-21 (Nov. 1982). Translation of: *Zh. Prikl. Spektrosk. (USSR)*, vol.37, no.5, p.722-4 (Nov. 1982). [received: Sept. 1983]
Because of the practical needs of the technology of manufacture of semiconductor materials with desired parameters, it is necessary to develop highly sensitive methods for analysis of germanium and silicon used both in monitoring the purity of the starting materials for semiconductor preparation and for monitoring the technological process of their doping. The combined use of direct spectrographic methods with preconcentration of impurities is of interest in the analysis of various semiconductor materials based on germanium and silicon. Because of the increased requirements imposed by manufacture of semiconductor substances, it is necessary to lower the limits of detection of impurity elements. The greatest possibilities for lowering the detection limits by spectrographic analysis of semiconductor germanium and silicon consist in optimization of the spectrum excitation processes. One of the promising ways is the use of a hollow-cathode discharge as the excitation source. Using this light source, the authors have developed direct spectrographic methods for analysis of germanium and silicon and also a method for analysis of germanium with chemical preconcentration of impurities. (1 ref.)

109827 Distribution of laser erosion products on a substrate and its use for spectral analysis. V.I.Derzhitskaya, M.L.Petukh, A.A.Yankovskii.
J. Appl. Spectrosc. (USA), vol.37, no.5, p.1222-4 (Nov. 1982). Translation of: *Zh. Prikl. Spektrosk. (USSR)*, vol.37, no.5, p.724-7 (Nov. 1982). [received: Sept. 1983]
The method of emission spectral analysis can be used to determine the thickness and composition of thin coatings. Lasers permit analyzing arbitrary coatings on both electrically conducting and nonconducting substrates using the same method. In order to increase the sensitivity of determination of low concentrations, lasers are usually used together with electrical discharges. The authors used a variant of this method in which the operations of laser removal of a specimen and its evaporation in electrical discharges were separated. (3 refs.)

109828 Simultaneous radiochemical determination of chemically similar elements by the method of concentration dependent distribution. II. Theory of the method based on substoichiometric masking and auxiliary extractants. M.Kyrs, J.Halova (Nuclear Res. Inst., Rez, Czechoslovakia).
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.29-41 (1983).
For pt.I see ibid., vol.52, p.53 (1979). The distribution of a radioactively labelled substance was measured in two different solvent extraction systems in the presence of substoichiometric amounts of different masking reagents. The theory of the errors involved in the method is elaborated, recommendations are given for the choice of the conditions of the determination, e.g. which combination of extractant and masking reagent is preferable, which of the two elements should be labelled, what is the optimum concentration of the masking reagent and what values of distribution ratios are desirable. (12 refs.)

109829 Polarographic waves of tri-n-butyl phosphate and polarographic determination of uranium in the presence of tri-n-butyl phosphate. A.Sobkowska (Dept. of Analytical Chem., Inst. of Nuclear Res., Warszawa, Poland).
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.43-51 (1983).
The results of a study on the polarographic behaviour of TBP and its influence on the determination of uranyl ions is presented. The half-wave potential of the adsorption wave of TBP depends on the concentration of TBP, type of supporting electrolyte and its concentration. In the presence of TBP the polarographic wave of U(VI) ion is changed. Below 7×10^{-5} M TBP the polarographic wave of U(VI) is not affected, between 7×10^{-5} and 2×10^{-4} M TBP the shape, height and half-wave potential of U(VI) waves are changed and above 2×10^{-4} M, up to saturated solution of TBP, the waves of U(VI) do not change further. (15 refs.)

109830 Calibration of Micromatter Co. standards used for the calibration of PIXE analysis systems. D.W.Mingay (Phys. Div., Atomic Energy Board, Pretoria, S Africa).
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.127-35 (1983).
The evaluation of the accuracy of thin elemental standards produced by Micromatter Co., which are widely used for the calibration of the detection sensitivity of PIXE analysis systems, is presented in terms of Rutherford scattering measurements of the thickness of 68 standards covering a range of 59 different elements. (14 refs.)

109831 Estimation of depth profiles of boron in silicon on ion beam etched sloping cuts by means of neutron induced autoradiography. K.Freyer, H.C.Treutler, G.Deuretzbacher, J.Flachowsky (Central Inst. for Isotope & Radiation Res., Acad. of Sci., Leipzig, Germany).
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.149-53 (1983).
A new method for the estimation of depth profiles of boron in silicon in extremely thin layers by means of neutron induced autoradiography is described. By the aid of ion beam etching it is possible to produce sloping cuts with angles down to 10^{-4}-$10^{-5\circ}$. This means an extension of the depth profile by a factor of up to 5×10^4. In this way a depth resolution of about ±10 nm is possible. The autoradiographic model of the sloping cut for the evaluation is described and first results are discussed. (7 refs.)

109832 Quantitative autoradiography of semiconductor materials with phosphorus diffusion standards. H.C.Treutler, K.Freyer (Central Inst. for Isotope & Radiation Res., Acad. of Sci., Leipzig, Germany), J.Dubnack.
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.155-63 (1983). In German.
A suitable standard sample was developed and tested on the basis of phosphorus for the quantitative autoradiography of elements of interest in semiconductor technology. By the aid of silicon disks with a phosphorus concentration of 6×10^{17} atoms.cm^{-2} the error of the quantitative autoradiographic method is determined. The relative mean error of the density measurement is at best ±4%; the relative mean error of the determination of phosphorus concentration by use of an error-free standard sample is about ±15%. This method will be extended to other elements by use of this standard sample of phosphorus. (no refs.)

109833 Rutherford backscattering with heavy ions. I. Mass and depth resolution. R.T.Sullins, C.V.Barros Leite, E.A.Schweikert (Center for Trace Characterization, Texas A&M Univ., College Station, TX, USA).
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.171-9 (1983).
The analytical features of using heavy ions for Rutherford backscattering spectrometry, particularly the mass and depth resolution capabilities, are discussed. (8 refs.)

109834 Rutherford backscattering with heavy ions. II. Sensitivities and applications. R.T.Sullins, C.V.Barros Leite, E.A.Schweikert (Center for Trace Characterization, Texas A&M Univ., College Station, TX, USA).
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.181-7 (1983).
For pt.I see ibid., vol.78, p.171-9 (1983). The authors extend the discussions of Part I to include quantitative aspects of heavy ion Rutherford backscattering and present examples of its application. (3 refs.)

109835 Trace elements in Turkish tobacco determined by instrumental neutron activation analysis. M.C.Gulovali (Ankara Nuclear Res. & Training Center, Ankara, Turkey), G.Gunduz.
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.189-98 (1983).
The concentration of 20 trace elements in nine different brands of Turkish cigarette tobacco and in a brand of pipe tobacco and in tobacco ash has been determined by instrumental neutron activation analysis. The percent transference of elements into smoke has been estimated from the amounts remaining in the ash. (13 refs.)

109836 Pulsed-laser atom-probe FIM study of solid surfaces. T.T.Tsong, T.J.Kinkus (Phys. Dept., Pennsylvania State Univ., University Park, PA, USA).
Phys. Scr. (Sweden), vol.T4, p.201-3 (1983). (Nordic Conference on Surface Science, Tampere, Finland, 18-20 Aug. 1982).
A linear type pulsed-laser time of flight atom-probe field ion microscope has been developed which uses laser pulses of 300 ps from a nitrogen laser for field desorbing surface atoms. It is a time of flight mass spectrometer and an ion energy analyzer of single atom detecting sensitivity with good mass and energy resolution. The new system is used to study the energy distribution of field desorbed inert gas atoms such as Ne^+ and Ar^+, and field evaporated metal ions. The formation of metal helide ions such as $RhHe^{++}$, $PtHe^{++}$ and $PtHe_2^{++}$, and metal hybrid ions such as AuH^+, AuH_2^+, and AuH_3^+ has been studied by observing both the mass spectra and the energy distributions. The formation of H^+, H_2^+, and H_3^+ from atomically well defined metal surfaces under the influence of an applied field is also studied. (10 refs.)

109837 ESCA studies on silicon compounds using an internal standard for calibration. B.Folkesson (Inorganic Chem. 1, Chem. Center, Univ. of Lund, Lund, Sweden).
Spectrosc. Lett. (USA), vol.16, no.7, p.531-9 (1983).
X-ray photoelectron spectra (ESCA) for some silicon compounds have been measured. As an internal standard the Cls binding energy of the carbon atoms of incorporated phenyl groups have been used. In this way a correlation between the binding energy of the silicon atom (Si2p) and its effective charge (q_{Si}) could be set up: $E_b=1.53\ q+100.6$. (17 refs.)

109838 ESCA study of the adhesion of Ag, Cu and Ni to polysiloxane resins used in the semiconductor industry. A.Torrisi, G.Marletta, O.Puglisi, S.Pignataro (Istituto Dipartimentale di Chimica e Chimica Industriale, Univ. di Catania, Catania, Italy).
Surf. & Interface Anal. (GB), vol.5, no.4, p.161-6 (Aug. 1983). (International Conference on Quantitative Surface Analysis, Teddington, England, 24-25 Nov. 1981).
Commercial polysiloxane resins used in the semiconductor industry were moulded on Ag, Ni and Cu real surfaces. The samples were broken by using a pull test machine and the joint strength measured. The 'resin' and 'metal' faces obtained in the rupture process were analysed by ESCA. The chemical composition of the two faces was very different. The one from the resin side resembled that of the bulk. That from the metal side was rich in additives from the commercial resin. Some differences were found between the three metals, whilst the spiral flow of the resin in the range examined influenced the results in only a very limited way. The weak boundary layer in which the above additives accumulate seems responsible for the low adhesion level found. The Pb/Si concentration ratio at the fracture locus is correlated with the adhesive joint strength. The multifactorial nature of the adhesion in practical samples is discussed. It is suggested that the influence of the heavy elements present in the additive has to be explored in connection not only with the adhesion problem but also with the electrical reliability of the device. (16 refs.)

109839 Fabrication of a low cost controlled potential coulometer. M.Venkataramaiah, G.N.Rao, R.Mulchandani (Indian Inst. of Technol., New Delhi, India).
Trans. SAEST (India), vol.18, no.1, p.59-65 (Jan.-March 1983).
A new circuit using locally available IC operational amplifiers has been designed and a controlled potential digital coulometer has been fabricated. The unit gave satisfactory results. The cost of the unit including the power supply is estimated to be about four thousand rupees. (3 refs.)

82.90 OTHER TOPICS IN PHYSICAL CHEMISTRY

109840 Mixing in mechanically agitated gas-liquid contactors, bubble columns and modified bubble columns. A.B.Pandit, J.B.Joshi (Dept. of Chem. Technol., Univ. of Bombay, Bombay, India).
Chem. Eng. Sci. (GB), vol.38, no.8, p.1189-215 (1983).
Mixing time measurements were made in 300 and 1000 mm mechanically agitated contactors with different types of impellers, located at different heights from the bottom of the vessel. Mixing time measurements were also made in 150, 200, 385 and 1000 mm bubble columns with varying liquid heights. Transient pH measurement and conductivity measurement were used to measure the mixing times. Impeller speed was varied in the range of 3.33-20 r/sec in the case of mechanically agitated contactors and gas superficial velocity was varied in the range of 10-250 mm/sec in bubble columns. Effect of physical properties of the fluid (surface tension, ionic strength, liquid viscosity) and that of the nonNewtonian behavior on mixing time was studied. Mixing time in the presence of drag reducing agents was also investigated. A procedure is given for the prediction of the critical impeller speed for gas phase dispersion in mechanically agitated contactors. (23 refs.)

109841 Parameter evaluation of an extractor with back mixing. A.Heyberger, M.Kratky, J.Prochazka (Inst. of Chem. Process Fundamentals, Czechoslovak Acad. of Sci., Prague, Czechoslovakia).
Chem. Eng. Sci. (GB), vol.38, no.8, p.1303-7 (1983).
From measured longitudinal solute concentration profiles in a vibrating plate extraction column parameters of a stagewise model with back mixing were evaluated as functions of the axial coordinate of the column. In the model the parameters were represented by polynomials of the stage number and the dependence of model error on the degrees of the polynomials was studied. Very good agreement of measured and calculated concentration profiles was obtained with polynomials of not higher than 4th degree, whereas the model with constant parameters in most cases failed to describe adequately the profiles and the exit concentrations. As a possible cause of the variability of parameters along the column the existence of hold-up profiles is suggested. (6 refs.)

86.00 ENERGY RESEARCH AND ENVIRONMENTAL SCIENCE

86.10 ENERGY RESOURCES AND THEIR UTILISATION

(inc. economic aspects; for nuclear engineering and nuclear power studies, see 28.00)

109842 Technology characterization for energy system analysis. S.Koyama, T.Kashihara, E.Endo (Electrotech. Lab., Ibaraki, Japan).
Bull. Electrotech. Lab. (Japan), vol.47, no.4, p.284-309 (1983). In Japanese.
An international collaborative project, Energy System Analysis Project (SA), was conducted by the International Energy Agency (IEA) from 1976 to 1979 to provide analytical information for development of IEA energy R&D strategy. Based on the result of the project, another project, Energy Technology System Analysis Project (ETSAP), was started by the IEA in November 1980, scheduled to last for two years. Main subjects expected in the first year are the characterization of energy technologies and the transfer of energy system model 'MARKAL' to participating countries. A main subject expected in the second year is the analysis of energy system by the use of MARKAL and the data obtained in the first year. These subjects have been carried out according to a task sharing sheme. Japan has started the role of characterizing 27 technologies, of which 14 are to be characterized at the Electrotechnical Laboratory through collaboration with specialists of respective technologies. The basic definition of main data items, concept of data adjustment, and collected and adjusted data are summarized. (29 refs.)

109843 Case study, candidate technologies to relieve the European energy systems: Ireland. L.Killen.
Report EUR 8035 EN, Comm. European Communities, Luxembourg (1982), 50 pp.
Presents the results for Ireland of the case study entitled 'Candidate Technologies to relieve the European Energy System', using the EFOM-12-C model. The previous case study, 'The Escalating Supply Rationing' examined the sensitivity of the European energy systems to progressive restrictions in energy imports. The results for Ireland were not flexible in this regard, with a maximum saving of only 6% in the cost of energy imports possible, and this was achieved at the expense of an increase of 19% in total system cost. This reflects the relatively insecure situation in which Ireland finds itself, with very few indigenous energy resources and therefore a high dependence upon imported energy, and in particular upon imported oil.

86.10B Fossil and other fuels

109844 Coal gasification—the proof of the pudding. N.A.Holt (Electric Power Res. Inst., Palo Alto, CA, USA).
Mod. Power Syst. (USA), vol.3, no.6, p.20-8 (June 1983).
By removing the sulphur bearing and particulate matter from the gas prior to combustion, coal gasification offers attractive schemes for environmentally superior domestic resource based plants. Currently, the Lurgi dry ash, Koppers-Totzek, Winkler and Wellman Galusha processes are operated commercially. However, at this time only the small Wellman producers are in use in the USA. A Lurgi dry ash plant based on North Dakota lignite is under construction for Great Plains Associates. Proposals for plants based on the Koppers-Totzek and Winkler processes and other gasification technologies are currently before the US Synthetic Fuels Corporation. Over the next five years several other coal gasification processes should be demonstrated at commercial sizes. They include the Texaco, British Gas Corporation/Lurgi, Shell, Westinghouse, pressurised Winkler, and Allis-Chalmers Kilngas processes. Commercial operation on a larger scale is expected in the 1990s. (no refs.)

109845 Resource and energy management of synfuels production with hydrogen and oxygen requirements from electrolysis. R.H.Shannon, R.D.Richardson.
Int. J. Hydrogen Energy (GB), vol.8, no.10, p.783-92 (1983).
The Resource and Energy Management System (REM) is an integrated self-sufficient system for the efficient and clean recovery of synthetic crudes at high yields from a variety of heavy hydrocarbon deposits. The system integrates the following: heavy oil/tar sand bitumen/shale oil/coal recovery; upgrading by 'hydrogen addition'; residual oil/coal gasification; and combined cycle electricity generation for water electrolysis. Recovered heavy hydrocarbons are upgraded by 'hydrogen addition'. Hydrogen is available, in the REM system, from electrolysis, from gasifying the waste carbonaceous residues from upgrading and from gasifying coal. Gasification is efficiently carried out with oxygen, available from electrolysis. Gasifier synthesis gases are also used in a combined-cycle power system to generate power. Power, produced economically by this means, is used to electrolyse water which is the source of hydrogen for upgrading and of oxygen for gasification. Favourable technical and economic circumstances now prevail for the commercialization of large-scale electrolytic units in the synfuels industry according to a technical and economic analysis. (19 refs.)

109846 An airline view of LH2 as a fuel for commercial aircraft. K.G.Wilkinson.
Int. J. Hydrogen Energy (GB), vol.8, no.10, p.793-6 (1983).
Fuel for air transport is a particularly important matter, because it is an energy-intensive form of transport. Price and energy density are therefore correspondingly critical. Airlines' views tend to be short term because there is no future if they do not survive tomorrow. Thus, although petroleum supply and price has been unstable since 1973, airlines' primary concern has been with economizing the use of fuel and specifying more fuel economic equipment for the future, rather than serious pursuit of more radical solutions. LH2 gives promise of being a serious candidate for the longer term but there is not yet convincing proof that cheaper seat mile costs could be produced in today's circumstances. This situation could be changed by the realization of laminar flow by surface cooling at subsonic speeds. There is a strong case for a modest programme of carefully aimed research on an international basis to fill the most important gaps in our knowledge on the design of LH2 fueled aircraft. Future crises in energy supplies may well raise questions of transport fuel strategy which will heed this background for wise decision-making. Particular significance attaches to the place of nuclear power in world energy policy since this dominates the question of LH2 availability and price. (2 refs.)

86.10D Wind energy

109847 Economic evaluation of wind energy applications for remote location power supply.. P.C.Bandopadhayay (Div. of Energy Technol., CSIRO., Highett, Victoria, Australia).
Wind Eng. (GB), vol.7, no.2, p.67-78 (1983).
An economic evaluation methodology based on the Present Value Analysis is proposed. In this method, graphical representations of the system performance and the economic requirements are used to examine the economic implications of using Wind Energy Conversion Systems (WECS) to supply electrical power to an isolated user. The method can also be used to determine the optimum sizes of the wind energy convertor and the electrical storage size of the simple WECS. The cost of electricity generation using a Total Energy Wind Conversion System is compared, using Present Value Analysis, with that of a WECS and a liquid fuel operated generating system. (4 refs.)

109848 The Weibull distribution function and wind power statistics.. G.J.Bowden, P.R.Barker, V.O.Shestopal, J.W.Twidell (School of Phys., Univ. of New South Wales, Kensington, NSW, Australia).
Wind Eng. (GB), vol.7, no.2, p.85-98 (1983).
The properties of the Weibull distribution function are used to show that there are some simple relationships between the Weibull parameters (K,c) and the wind speed moments $(\bar{v},\bar{v}^3)$. In particular, to within 1%, $\bar{v}={}^{1}/_{2}\pi^{1/2}c$ (for $1.6\leq k\leq 3.0$) and $\bar{v}^3={}^{1}/_{2}\pi^{1/2}(3c^3/k)$ (for $1.8\leq k\leq 2.3$). These results are subsequently used to examine the relationship between seasonal, yearly and many-yearly Weibull parameters for a given site. Some simple 'sum-rules' are derived which conserve their time-averaged moments $\bar{v}$ and $\bar{v}^3$. These sum rules are used, in turn, to suggest a 'generalised Weibull distribution function' which can be used to model the fluctuation, which will occur from year to year, in the average moments $\bar{v}$ and $\bar{v}^3$. In addition, some new results for Lord Howe Island are presented, which show that the annual wind speed, at selected sites is $\sim 8.1\ \mathrm{ms}^{-1}$. Finally some comments are also made concerning the choice of distribution function to model wind speed statistics. (17 refs.)

109849 A strategy for optimization of wind energy systems. S.Westberg (Dept. of Mech. Engng., Univ. of Linkoping, Linkoping, Sweden).
Wind Eng. (GB), vol.7, no.2, p.104-14 (1983).
The paper presents a strategy to deal with wind energy systems as an optimization problem. An attempt is made to create a general procedure to describe a complete system. The system is divided into three independent parts, the application, the wind turbine and the state of wind. In this way the problem becomes more tractable and each part can easily be changed while the others are unaffected. An illustrative example is described where a wind rotor is directly connected to the compressor of a heat pump. (6 refs.)

86.10K Solar energy

109850 Directional intercept factor of truncated CPCs. J.C.Minano (Univ. Politecnica, Inst. de Energia Solar, ETSI Telecomunicacion, Ciudad Univ., Madrid, Spain).
Appl. Opt. (USA), vol.22, no.17, p.2747-50 (1983).
The fraction of power reaching the collector of a truncated cylindrical compound parabolic concentrator, out of the total power arriving as its entry aperture in a given direction, is calculated without ray tracing for all directions. (5 refs.)

109851 Limit of concentration under extended nonhomogeneous light sources. J.C.Minano, A.Luque (Inst. de Energia Solar, Ciudad Univ., Madrid, Spain).
Appl. Opt. (USA), vol.22, no.17, p.2751-60 (1983).
Static photovoltaic concentrators, which see the sky as an extended distribution of radiance, are analyzed in a general way. The rules for achieving the highest energy on the cell are derived and the appropriate figures of merit are defined. It is concluded that casting increasingly high values of energy on the cell, which would be bifacial, require collecting a lower portion of the total sky energy. The corresponding figures of merit for the concentrators of the CPC family are analyzed, concluding that a better type of concentrator should be developed for photovoltaic applications. (5 refs.)

109852 Automatic methods of adjusting facet concentrators and heliostats. R.A.Zakhidov, R.A.Khakimov, A.A.Abdurakhmanov, Yu.M.Sizov, V.K.Baranov (Central Design Office of Sci. Instrument Manufacture, Acad. of Sci., Uzbek SSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.27-30 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.23-6 (1982). [received: Aug. 1983]
Automatic adjustment devices for mirror elements have been developed to automate the process of adjustment of facet concentrators, thus substantially reducing the amount of time and effort involved in adjustment. In addition, by storing the adjusted position, it is possible to automatically activate and deactivate individual mirror elements. This makes it possible to regulate the light flux in the focal region of facet concentrators. The remote control unit for facets is an element of a facet-concentrator prototype and is intended for developing automatic methods of adjusting groups of facets. It includes a framework, a group of 10 facets with individual drives, reducers, and a control panel. (4 refs.)

109853 Investigation of the equations of motion of the heliostats of a tower-type solar electric power plant. M.N.Kachanovskii, V.M.Dubilovich (Krzhizhanovskii Sci. Res. Inst. of Power Engng., USSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.37-42 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.31-5 (1982). [received: Aug. 1983]
The authors obtain equations for determining the position and speed of rotation of heliostats at 'antishadow' points. (3 refs.)

109854 Investigation of accumulated energy and thermal conditions in shed-type hothouses. A.I.Imamkulov, Yu.N.Yakubov (Ordzhonikidze Bukhara State Pedagogical Inst., USSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.61-4 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.50-3 (1982). [received: Aug. 1983]
The authors investigate the thermal conditions in their radically new design for shed-type and traditional hothouses, and also of commercial shed-type and traditional hothouses with an area of 300 and 500 m^2. (3 refs.)

109855 On the determination of the heat-insulating characteristics of transparent film shielding for solar hothouses. A.T.Temurkhanov, A.B.Vardiashvili, G.Ya.Umarov, V.D.Kim (Alimdzhan Karshin State Pedagogical Inst., USSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.65-70 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.53-8 (1982). [received: Aug. 1983]
Considers two-layer film shielding and buffer film shielding. Tests were conducted using two identical model installations 1×0.44×0.34 m in size. To reduce heat loss, the windows of the installation were two-layer windows with a glass-wall filler. The installations were heated by means of 600-W electric heaters. The heating level was adjusted by means of a laboratory transformer. The temperature inside the model and in the transparent shielding was measured. The measurement errors were taken into account. It is seen that, in the case of film shielding, the heat-transfer coefficient of buffer insulation is 10-12% lower than for two-layer insulation. (3 refs.)

109856 Incoming direct solar radiation onto an arbitrary surface. A.Galkanov (Voroshilovgrad Machine Building Inst., USSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.74-6 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.61-3 (1982). [received: Aug. 1983]
The author derives a formula for computing the amount of direct solar radiation at a point on a specified surface. (1 ref.)

109857 Problem of accumulation of solar energy in the form of heat. Yu.A.Yakubov, A.I.Imamkulov, N.K.Radzhabov (Ordzhonikidze Bukhara State Pedagogical Inst., USSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.77-81 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.63-6 (1982). [received: Aug. 1983]
The authors investigate the possibility of accumulating solar energy in hothouses, and develop an optimality efficient hothouse design. The problem of accumulation obviously requires optimization of the amount of energy accumulated in solar installations with observance of the following conditions: 1) maximum entry of radiation; 2) minimum heat loss through enclosing surface of absorber; 3) optimization of heat-accumulating materials with optimal dimensions. These conditions are considered. (3 refs.)

109858 Heliothermic index for the evaluation of the potential of solar energy. R.Dogniaux (Inst. Royal Meteorologique de Belgique, Brussels, Belgium).
Int. J. Sol. Energy (Switzerland), vol.1, no.6, p.441-9 (1983).
The object of the present note is to propose and define simple index for characterizing and differentiating, at the mesoscale range, climatic areas answering criteria suited for heliothermic applications. The meteorological elements most liable to influence the behaviour of heliothermic systems are solar and atmospheric irradiances, air temperature and wind speed. It is thus quite natural to call on a simple function of these variables to define, as simply as possible, heliothermic index that can be applied to glass-shielded systems. (3 refs.)

109859 Analysis of solar sand heater. S.Singh, S.Ram, N.K.Bansal (Centre of Energy Studies, Indian Inst. of Technol., New Delhi, India).
Int. J. Energy Res. (GB), vol.7, no.3, p.241-53 (July-Sept. 1983).
This paper presents an analysis of an air/water heater, consisting of pipes, laid in a solid block; the surface of the block exposed to the sun is blackened and glazed, whereas the other surface is insulated, with outer surface of the insulation being in contact with ambient air. The block can consist of sand (laboratory model heater) (Sodha et al., 1980) or a south facing wall or roof; thus the concept represents an integration of the heater with the building. The modes of operation considered are (i) when the glazing is not insulated at night and (ii) when the glazing is insulated at night. (5 refs.)

109860 Economic comparison of solar absorption and photovoltaic-assisted vapour compression cooling systems. S.Ayyash, M.Sartawi (Kuwait Inst. for Sci. Res., Safat, Kuwait).
Int. J. Energy Res. (GB), vol.7, no.3, p.279-88 (July-Sept. 1983).
When the solar absorption and vapour compression cooling systems are viewed from the point of view of electrical energy consumption the differences between them can be expressed in terms of electrical energy saving with the former. As such, it is proposed that an economic comparison between photovoltaic-assisted vapour compression and solar absorption cooling systems be conducted, assuming that the former receives an amount of solar electricity equal to the potential electrical energy saving with the latter. The comparison is conducted with particular emphasis on the operational conditions in Kuwait. Analysis has shown that the potential electrical energy saving with a solar absorption cooling system is equal to 16 per cent of its refrigeration generation. The cost of supplying an equal amount of solar electricity is compared with the difference between the life-time costs of a solar absorption system and an equivalent vapour compression system. The economic comparison is conducted on the basis of the difference between the net present values of both systems. Given the current cost estimates and the prevailing climatic conditions in Kuwait it is shown that photovoltaic-assisted vapour compression cooling systems are likely to compete with the solar absorption cooling systems. This is particularly true in such applications where cooling is required for few hours during the day, and as the cost of the photovoltaic system decreases. (6 refs.)

109861 Transient performance of closed loop solar water heating system with heat exchanger. G.N.Tiwari, B.N.Sharma, A.Srivastava (Centre of Energy Studies, Indian Inst. of Technol., New Delhi, India).
Int. J. Energy Res. (GB), vol.7, no.3, p.289-94 (July-Sept. 1983).
The present paper deals with an analysis of a forced circulation closed loop solar water heating system; withdrawal of hot water of constant flow rate from a storage tank through a heat exchanger is considered. The effect of flow rate and heat exchanger length on the performance has also been discussed for a typical set of parameters and for a typical cold day in Delhi (26 January 1980). (4 refs.)

109862 Shade beneath solar collectors: a potential agriculture resource. R.H.Sauer (Pacific Northwest Lab., Richland, WA, USA).
Sol. Energy (USA), vol.31, no.4, p.411-14 (1983).
At a solar generating station, the solar collectors would provide the shade, as do the shrubs, but unlike the shrubs, would not compete for the limited water supply. The reduced heat and drought beneath the collectors may increase vegetative productivity to the point where harvesting a crop would be economical. The objective of this research was to study changes in the soil water and temperature conditions and plant production in the shade, compared to an unshaded area. The partial shade beneath solar collectors in the desert appears to offer better growing conditions compared to an unshaded area, with respect to soil water content and air temperature. However, in this research, the test plants did not show a positive response to the better growing conditions, possibly because too much light was excluded. These results suggest this approach to making use of the otherwise unused soil beneath solar collectors should be pursued. (5 refs.)

86.10N Nuclear energy

109863 The availability of uranium, thorium and heavy water in the world in the light of the results of the INFCE study. M.Petrovic (Savezni Komitet za energetiku, Beobrad, Yugoslavia).
Elektroprivreda (Yugoslavia), vol.36, no.5-6, p.188-97 (May-June 1983). In Croatian.
Gives a brief review of the results of two years of work on the INFCE study in the part related to the long-term development in the world of the industry of nuclear raw materials (uranium and thorium) and heavy water, in which the author also took part on behalf of Yugoslavia. In accordance with the estimated development of the nuclear industry up to the year 2025, as well as with the possible development of individual technologies of the nuclear fuel cycle and reactor systems, the demand in the world for nuclear raw materials and heavy water, as well as the possibilities to meet this demand have been estimated. (5 refs.)

109864 Zinc-air cells: power source of the future. R.E.Pytches (Gould Micropower Products Div., Wrexham, Wales).
Electron. & Power (GB), vol.29, no.7-8, p.577-80 (July-Aug. 1983).
Modern-day microelectronic products demand similarly miniaturised reliable power sources, in some cases even operating in a standby mode. This article states the case for the zinc-air cell, originally used in hearing aids, as opposed to its main competitors. (no refs.)

109865 The prediction of the state-of-charge of some commercial primary cells. S.A.G.R.Karunathilaka, N.A.Hampson, M.Hughes (Dept. of Chem., Univ. of Technol., Loughborough, England), W.G.Marshall, R.Leek, T.J.Sinclair.
J. Appl. Electrochem. (GB), vol.13, no.5, p.577-86 (Sept. 1983).
Research carried out at Loughborough during the last five years of the impedance of Leclanche, alkaline Zn-MnO_2, alkaline Zn-HgO, Li-CuO, Li-SO_2, Li-$SOCl_2$ primary cells is briefly reviewed. The use of alternating current methods for the estimation of the state of charge of the cells is discussed. A search was made for properties of the impedance of each cell system which change in a marked and reliable manner when a prescribed amount of charge is withdrawn from the cell. It is concluded that simple tests based upon an assessment of these properties are adequate for the estimation of the state of charge of some of the systems studied. However, other systems are not so 'well-behaved'. The impedance of each cell changed significantly during discharge and, although making measurements of these changes would enable the state of charge to be estimated, the test techniques required would not necessarily be simple. Using the results obtained on the impedance of the cells, test sets have been constructed which provide a digital presentation of the open-circuit voltage and the state of charge of Leclanche cells (Ever Ready type SP11), mercury cells (Mallory, type RM502R) and lithium cells (Mallory, type L032S and SAFT, type LC01). The electronic techniques employed in these test sets are described in outline with reference in block-schematic diagrams. A proposal is made for the construction of a general-purpose tester for primary cells which would incorporate microprocessors and provide an indication of state of charge based upon data relating to impedance, temperature and discharge history. The tester might also be made self-calibrating for field use. (13 refs.)

109866 Corrosion and polarisation characteristics of zinc in battery electrolyte analogues and the effect of amalgamation. L.M.Baugh, F.L.Tye, N.C.White (Group Tech. Centre, Berec Group Ltd., London, England).
J. Appl. Electrochem. (GB), vol.13, no.5, p.623-35 (Sept. 1983).
The corrosion and polarization characteristics of zinc have been investigated in concentrated NH_4Cl and NaCl solutions which represent suitable electrolyte analogues for Leclanche and zinc chloride cells, respectively. The effects of zinc amalgamation in the range 0-1 mg Hg cm^{-2} have also been examined and the results compared and contrasted with those obtained in concentrated KOH solution which is a useful electrolyte analogue for alkaline cells. It is

shown that the structure of the zinc-solution interphase and the electrochemical reactions which occur are critically dependent upon the particular electrolyte considered. Despite this, the absolute corrosion rates of unamalgamated zinc are of the same order. This is an unexpected result. The effectiveness with which both dissolved zinc salts and mercury reduce the corrosion rate decreases in the electrolyte order $KOH \gtrsim NH_4Cl > NaCl$. This is explained by the increasing participation of diffusion as the factor which controls the rate of the cathodic hydrogen evolution process. Maximum effectiveness for corrosion inhibition is approached when the mercury level exceeds 100 $\mu g\ cm^{-2}$. At this concntration, coverage of the surface by a zince rich almalgam of almost constant composition is complete. (15 refs.)

109867 The impedance of the lithium-thionyl chloride primary cell. M.Hughes, S.A.G.R.Karunathilaka, N.A.Hampson (Chem. Dept., Univ. of Technol., Loughborough, England), T.J.Sinclair.
J. Appl. Electrochem. (GB), vol.13, no.5, p.669-78 (Sept. 1983).
The impedances of nominally fully charged and partially discharged $Li/SOCl_2$ cells have been measured in the frequency range 10 kHz-6 mHz. The data have been interpreted using an analogue technique in terms of the most probable cell reactions. The possibilities of state-of-charge tests based on the impedance technique are discussed. The most promising parameter for a residual capacity test in the region 100-90% is the double-layer capacitance. (18 refs.)

109868 The delayed action of magnesium anodes in primary batteries. I. Experimental studies. B.V.R.Kumar, S.Sathyanarayana (Dept. of Inorganic & Phys. Chem., Indian Inst. of Sci., Bangalore, India).
J. Power Sources (Switzerland), vol.10, no.3, p.219-41 (Aug. 1983).
Magnesium exhibits a delayed dissolution on anodic polarisation owing to a slow, field-induced breakdown of the passive film on its surface. The phenomenon depends on several factors such as the pretreatment of the anode, the composition of the solution, etc. In order to clarify the mechanism of the field-induced film-breakdown process, a detailed experimental study of the delayed action and its dependence on several experimental variables such as ageing of anode in contact with the solution, the nature of the surfactant-coating on the magnesium anode, the anodic current density, etc., has been carried out. The results of the single electrode studies have been verified with improved $Mg-MnO_2$ dry cells. Finally, a probable mechanism based on a 'metal dissolution − film dilatation − film breakdown' model has been proposed in order to explain the delayed action under various experimental conditions. (20 refs.)

109869 The delayed action of magnesium anodes in primary batteries. II. Theoretical studies. S.Sathyanarayana, B.V.R.Kumar (Dept. of Inorganic & Phys. Chem., Indian Inst. of Sci., Bangalore, India).
J. Power Sources (Switzerland), vol.10, no.3, p.243-61 (Aug. 1983).
For pt.I, see ibid., vol.10, no.3, p.219 (1983). A physical model for the field-induced breakdown of the passive film on magnesium anodes has been developed based on experimental data on the delayed action of magnesium anodes. The model essentially involves, successively, metal dissolution at the metal-film interface, film-dilatation, and film breakdown. A theoretical analysis of the model has been carried out to obtain an explicit expression for the time dependence of the electrode potential during the delayed action phenomenon. The delay-time curves obtained are compared with experimental data, especially with regard to the effects of film thickness, ageing of the anode in solution, current density, temperature, etc. Finally, possible means of reducing the delayed action of magnesium anodes are predicted from the 'metal dissolution-film dilatation-film breakdown' model. (9 refs.)

109870 Lithium/thionyl-chloride cells. M.A.Jay.
New Electron. (GB), vol.16, no.14, p.54-6 (12 July 1983).
Describes the lithium/thionyl-chloride cell specific benefits. Energy density: $Li/SOCl_2$ provides a higher energy per unit volume and energy per unit mass than most other primary cells, giving up to 420 Wh/kg and 800 mWh/cm^3. Terminal voltage: $Li/SOCl_2$ has the highest open circuit voltage (3.68 V) and working voltage (3.4 V) of any commerically available primary cell. It also exhibits a very flat discharge characteristic, maintaining this voltage at a constant level until the cell becomes exhausted. Operating temperature range: the cell has a useful temperature range of −55 to 75°C. Long-term stability: the shelf life of the cell at room temperature is beyond 10 years. (no refs.)

109871 The answer's alkaline [primary cells]. B.Russell.
New Electron. (GB), vol.16, no.14, p.59-60 (12 July 1983).
Describes the alkaline system in which the zinc anode does not serve as a cell container and can be used in a granular powder form. This results in a very large anode surface that has the effect of increasing the life and the maximum current available from a given cell size. At the other electrode, a highly active form of manganese dioxide is pelleted and pressed against the inner surface of the cell container which also serves as the cathode current collector. The electrolyte is a highly conductive solution of potassium hydroxide which provides great mobility of ions over a wide variety of current drains and at a large range of temperatures. (no refs.)

109872 Zinc-air cells have unique properties. M.A.Jay.
New Electron. (GB), vol.16, no.14, p.62-4 (12 July 1983).
Describes zinc-air cells, which give instantaneous high power output, very stable discharge voltage and a high specific energy and low weight to volume ratio. Ambient air is allowed to permeate the cell and forms the positive electrode. Using air as an electrode gives the cell its unique properties. The air penetrates a cylinder of zinc powder in order to provide a surface for chemical reaction to take place. The cathode is gelled KOH and an alkaline electrolyte separates the anode and cathode. (no refs.)

86.30F Secondary cells

109873 Two-plateau rechargeable sodium/sulfur(IV) molten chloroaluminate cell. G.Mamantov, K.Tanemoto, Y.Ogata (Dept. of Chem., Univ. of Tennessee, Knoxville, TN, USA).
J. Electrochem. Soc. (USA), vol.130, no.7, p.1528-31 (July 1983).
The behavior of the rechargeable cell Na/β''-alumina/SCl_3^+ in molten $AlCl_3$-NaCl under conditions in which S(IV) is reduced to S(−2)is described. It is shown that the use of reticulated vitreous carbon as the positive current collector and high concentrations of active material result in cells which operate at temperatures ≤220°C and have very high energy densities (>450 W-hr/kg). (12 refs.)

109874 Design and performance of a sodium/sulphur multitube cell. R.Knoedler, R.Krapf (Central Res. Lab., Brown, Boveri & Cie AG, Heidelberg, Germany).
J. Power Sources (Switzerland), vol.10, no.3, p.263-70 (Aug. 1983).
Multiplate or multitube arrangements in battery designs generally result in higher specific energy and power values. Preliminary investigations into the design and operation of a 4-tube Na/S cell with a theoretical capacity of 155 A h showed values of 100 W h/kg for the energy density at the 3 h rate and of 6 mΩ for the cell resistance, corresponding to a maximum power density of 100 W/kg. With further improvements, values of 165 W h/kg and 180 W/kg can be expected to be realized. Another advantage of this design is reduced corrosion problems because the sulphur electrode can be put inside the β-Al_2O_3 tubes. A more complex fabrication process and a higher probability of failures may be considered as drawbacks of this design. (2 refs.)

109875 In situ conductance measurements of lead accumulator negative plates. M.Calabek (Dept. of Electrotechnol., Tech. Univ., Brno, Czechoslovakia), K.Micka, J.Sandera.
J. Power Sources (Switzerland), vol.10, no.3, p.271-8 (Aug. 1983).
The electrical conductance of negative lead-acid battery plates was measured in situ by the DC method. By subtracting the conductance of the grid, the conductance of the active mass was obtained. With freshly charged plates this was appreciably lower and increased with time; this effect was attributed to adsorption of hydrogen on lead. During cycling, a decrease in the conductance was observed which is discussed in terms of recrystallization of the active mass. The conductance of dry plates was found to be appreciably lower than that of wet plates. (5 refs.)

109876 Optimization of the vanadium oxide (V_6O_{13}) electrode in a nonaqueous secondary lithium cell. S.-N.Hua, S.Phang (CSIRO, Inst. of Energy & Earth Resources, Port Melbourne, Victoria, Australia).
J. Power Sources (Switzerland), vol.10, no.3, p.279-90 (Aug. 1983).
The V_6O_{13} electrode was tested in a nonaqueous Li cell using 1M $LiAsF_6$ in propylene carbonate-acetonitrile mixture as the electrolyte. It was shown that incorporation of acetylene black in the V_6O_{13} electrodes improved cell performance in terms of active material utilisation. Also, cells using hydrophilic microporous polypropylene separators, e.g. Celgard 5511 and 3501, displayed less resistive losses enabling larger charge/discharge rates to be used. Voltage changes in the cell were shown to be controlled almost entirely by the V_6O_{13} electrode. Analysis of the exausted V_6O_{13} electrodes showed that they contained at least 4 moles of lithium per mole of V_6O_{13}. (23 refs.)

109877 The effect of current density and thickness of the active mass upon the corrosion rate of the spines of lead-acid battery plates. T.Rogatchev, G.Papazov, D.Pavlov (Central Lab. of Electrochem. Power Sources, Bulgarian Acad. of Sci., Sofia, Bulgaria).
J. Power Sources (Switzerland), vol.10, no.3, p.291-303 (Aug. 1983).
The effect of current density and the thickness of the active mass upon the corrosion of the spines of tubular Pb acid batteries has been determined by measuring the corrosion rate by the weight loss method. The presence of antimony in the alloy decreases the overvoltage of the corrosion reaction. Study of electrodes of different active mass layer thickness shows that with increase in thickness the corrosion rate decreases. If the thickness is above 3 mm, the corrosion rate remains constant, and is affected only by the nature of the alloy. The density of the active mass does not affect the corrosion behaviour of the electrodes. The experimental results confirm the validity of the oxygen corrosion model. (11 refs.)

109878 Sodium tungsten bronze thin films: variation of chemical potential with sodium concentration. M.Green, K.Kang (Dept. of Electrical Engng., Imperial Coll., London, England).
Solid State Ionics (Netherlands), vol.8, no.4, p.281-9 (July 1983).
The method of fabrication of the solid-state electrochemical cell, ITO, $WO_3|Na$-β-alumina$|Na_xWO_3$, ITO is described. The equilibrium potential of the $Na_xWO_3|Na$-β-alumina electrode versus pure sodium (via a sodium amalgam electrode) has been determined as function of x in the range 2×10^{-4} to 0.97. A simple free-electron model has been used to find a theoretical expression for the non-ideal part of the chemical potential of Na_xWO_3 up to $x \approx 1/4$: the agreement between theory and experiment is within the experimental error. (22 refs.)

109879 Intercalation electrodes in copper solid-state cells. A.Padula, M.Patriarca, B.Scrosati (Istituto di Chimica Fisica, Univ. of Rome, Rome, Italy).
Solid State Ionics (Netherlands), vol.8, no.4, p.305-10 (July 1983).
The behaviour of transition-metal dichalcogenide intercalation electrodes in copper solid-state cells have been investigated by kinetic, diffusion and thermodynamic studies. The results indicate that the copper electro-intercalation process is reversible in the compounds examined, which are TiS_2 and NbS_2. The kinetics of the process are controlled by the diffusion of the electroactive species to and from the bulk of the electrode. (8 refs.)

109880 Solid electrolyte batteries and fast ion conducting glasses. Factors affecting a proposed merger. D.R.Uhlmann, H.L.Tuller, D.P.Button, M.Valez (MIT, Cambridge, MA, USA).
Wiss. Z. Friedrich-Schiller-Univ. Jena, Math. Naturwiss. Reihe (Germany), vol.32, no.2-3, p.285-302 (1983). In English. (Otto-Schott-Colloquium on the State of Optical Glass Research 1982, Jena, Germany, 1982).
The potential uses of glasses as solid electrolytes in high performance batteries are discussed. Following an initial discussion of goals for such batteries and the design of cells employing glass electrolytes attention is directed to the phenomena which are critical in this application, electrical conductivity and corrosion behaviour. Available data on fast ion conducting glasses are reviewed and related to models for transport. The authors also review the corrosion behaviour of oxide glasses in aqueous solution and in molten alkali metals. It is concluded that glasses make attractive condidates for battery electrolytes, but that future developments will depend critically on improvements in understanding of structure and transport. (52 refs.)

Experimental study of the effect of solar radiation reflected from the earth and its cloud cover on the thermal conditions of solar batteries used in one of the satellites of the Kosmos series .... See Entry 109885

86.30G Fuel cells

109881 Aluminium-air/oxygen battery system attractive for use in electric vehicles. D.Katrynioch, J.Ruch.
Electr. Veh. Dev. (GB), no.16, p.6-7 (Spring 1983).
The fuel cell development starting in the sixties supported new interest in metal-air cells. Several problems could be solved by application of results of materials research. Today's metal-air batteries achieve higher energy and power densities than common battery systems and are of interest for use in electric vehicles. (no refs.)

109882 Strategy for European fuel cell development. J.Jensen (Odense Univ., Odense, Denmark).
Electr. Veh. Dev. (GB), no.16, p.25-7 (Spring 1983).
Electric power generation by fuel cells exhibits pollution-free, high energy density conversion. The practical efficiency of the cells is 2-3 times higher than that of a thermal engine. They are, however, plagued by problems of corrosion, contamination of the electrodes and overvoltages. The key economic problem is the need for noble metal electrocatalysts, especially at lower temperatures. These problems are entirely materials problems, which could be solved by the development of new solid state components. This paper outlines and proposes a community programme which attempts: (1) to review current

engineering developments worldwide, to define the specific technical targets for transport and stationary applications and to assess the role of advanced fuel cells throughout Europe in the coming decades; (2) to provide data allowing selection of optimum materials for critical aspects of fuel cell operation by developing solid electrolytes stable to medium temperatures (150-250°C), improved non noble metal oxygen electrodes and new metal hydrides (anodes); (3) to assess the performance of medium temperature cells based on the valuated materials and to establish a preliminary economic evaluation enabling the set-up of an R&D strategy on materials fabrication, cell engineering and energy system infrastructure. (no refs.)

86.30J Photoelectric conversion: solar cells and arrays

109883 Effect of boron compensation on the photovoltaic properties of amorphous silicon solar cells. T.D.Moustakas, H.P.Maruska, R.Friedman, M.Hicks (Corporate Res. Lab., Exxon Res. & Engng. Co., Linden, NJ, USA).
Appl. Phys. Lett. (USA), vol.43, no.4, p.368-70 (15 Aug. 1983).
Intrinsic amorphous silicon films are normally slightly *n* type. As a result, in n^+-*i*-metal and n^+-*i*-p^+ solar cell structures the major potential barrier is at the *i-m* or *i* p^+ interfaces. Low levels of boron compensation of the *i* layer move the Fermi level down to midgap. Further increases in boron render the *i* layer slightly *p* type, and move the major barrier to the *i*-n^+ interface. Therefore, it becomes possible to tailor the level of boron doping throughout the *i* layer so as to achieve high electric fields in all regions of the layer, and thus maximize the short circuit current. (4 refs.)

109884 High-efficiency (21.4%) $Ga_{0.75}In_{0.25}As$/GaAs(E_g=1.15 eV) concentrator solar cells and the influence of lattice mismatch on performance. M.J.Ludowise, W.T.Dietze, R.Boettcher, N.Kaminar (Corporate Solid State Lab., Varian Associates Inc., Palo Alto, CA, USA).
Appl. Phys. Lett. (USA), vol.43, no.5, p.468-70 (1 Sept. 1983).
High-efficiency $Ga_{0.75}In_{0.25}As$/GaAs concentrator solar cells (E_g=1.15 eV, area=0.32 cm^2) have been fabricated and tested at 21.4% efficiency under 380 AM2.4 sun. The cell performance parameters of open-circuit voltage, fill factor, and efficiency are presented as functions of concentration up to 987 sun. The spectral response, and current-voltage characteristics under concentration, of cells grown by organometallic vapor phase epitaxy on graded and ungraded lattice-constant buffer layers are compared. It is shown that a graded lattice-constant buffer layer is necessary for high-efficiency performance. In general, $Ga_{0.75}In_{0.25}As$ cells have higher efficiencies and open-circuit voltages than Si cells (E_g=1.11 eV) for concentrations in excess of about 200 sun. (8 refs.)

109885 Experimental study of the effect of solar radiation reflected from the earth and its cloud cover on the thermal conditions of solar batteries used in one of the satellites of the Kosmos series. G.S.Daletskii, V.A.Karpukhin, M.M.Koltun, V.M.Kuznetsov (All Union Sci. Res. Inst. of Current Sources, USSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.1-4 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.3-5 (1982). [received: Aug. 1983]
The article describes experiments conducted with one of the satellites of the Kosmos series in 1981, which made possible the estimation of the flux density distribution of solar radiation reflected from the Earth and its cloud cover during orbits with minimum duration of the sunlit portion. (7 refs.)

109886 Silicon MDS and SDS solar elements. A.N.Shmyreva, L.T.Kirpatenko, Yu.I.Yakimenko (Kiev Polytech. Inst., Kiev, Ukrainian SSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.1720 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.15-18 (1982). [received: Aug. 1983]
Investigates silicon solar elements of lattice type with metal/thin oxide/Si and SnO_2/thin oxide/Si structures, in which the thin oxide ≤20 Å was obtained by chemical oxidation in aqueous solutions of hydrogen peroxide and hydrochloric acid. The oxide is highly dense, uniform over the thickness, and has a relatively small number of defects. The initial material for preparing the solar elements was supplied by monocrystalline p-type silicon with a (III) orientation and a resistivity of 10 ohm.cm. (1 ref.)

109887 Two-layer antireflection coating for silicon photoelements. M.M.Koltun, V.P.Matveev, E.A.Agaev (All Union Sci. Res. Inst. of Current Sources, USSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.43-5 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.36-8 (1982). [received: Aug. 1983]
The article deals with issues relating to further improvement of the properties of silicon photoelements by replacement of single-layer antireflection coatings by two-layer ones. (9 refs.)

109888 A study of built-in potential in *a*-Si solar cells by means of back-surface reflected electroabsorption. S.Nonomura, H.Okamoto, Y.Hamakawa (Faculty of Engng. Sci., Osaka Univ., Osaka, Japan).
Appl. Phys. A (Germany), vol.A32, no.1, p.31-8 (Sept. 1983).
The electroreflectance (ER) signal has been studied for the purpose of identifying the built-in field in practical amorphous silicon (*a*-Si:H) solar cells. Through both theoretical and experimental considerations, it has been confirmed that the ER signal essentially comes from the light which is reflected at the back surface and hence experiences the internal electric field within the *a*-Si:H layer. By analyzing the ER signal, which is really the back-surface reflected electroabsorption signal, the built-in potential V_b can be evaluated. This method has been applied to various types of *p-i-n* junction *a*-Si solar cells. V_b of a usual homojunction solar cell was about 0.85 V. Increases of V_b by 50~130 mV have been found in heterojunction solar cells constructed with *p*-type amorphous silicon carbide (*a*-SiC:H) and/or *n*-type microcrystalline silicon (μc-Si) as compared with homojunction *p-i-n* solar cells. Moreover, a clear dependence of V_b on the substrate materials has been observed. These experimental results are described in connection with cell performances. (12 refs.)

109889 Electroreflectance and photoinduced charge separation in electrochemically doped trans-polyacetylene liquid junction device. D.Peramunage (Dept. of Chem., Brooklyn Coll., City Univ. of New York, Brooklyn, NY, USA), W.Siripala, M.Tomkiewicz, D.S.Ginley.
Chem. Phys. Lett. (Netherlands), vol.99, no.5-6, p.479-82 (19 Aug. 1983).
Liquid junction solar cells, made from electrochemically doped p-type trans-polyacetylene in contact with aqueous solution of methyl viologen, were constructed. The turn-on potential was found to be +1.0 V versus SCE. The spectral response showed low quantum efficiency ($\approx 10^{-4}$) for photoinduced charge separation with a threshold around 1.5 eV. The electroreflectance showed the presence of two transitions at 1.45 and at 1.6 eV. A tentative assignment of these transitions is proposed. (23 refs.)

109890 Limitations on solar cell open-circuit voltage and efficiency. A.Meulenberg,Jr., R.A.Arndt (Solid State Phys. Dept., COMSAT Labs., Clarksburg, MD, USA).
COMSAT Tech. Rev. (USA), vol.13, no.1, p.57-70 (Spring 1983).
Open-circuit voltages (V_{oc}) in 0.1 Ω-cm, n^+/p type, planar surface silicon solar cells produced by diffusion techniques are presently ≤654 mV, with corresponding conversion efficiencies of about 15 percent. This is lower than has been theoretically predicted. Experimental evidence is presented to demonstrate that the emitter is the largest source of the dark current that limits the attainment of higher V_{oc} values and, hence, reduces conversion efficiency. It is also shown that junction recombination current contributes to reduced V_{oc}. Because there is a lower limit on dark current from the base, even if the emitter and junction recombination currents are reduced to zero, a maximum V_{oc} of 695 mV is predicted, with a related conversion efficiency of 16.4 percent. (11 refs.)

109891 Sprayed CdS-Cu_2S solar cells. II. Preparation of CdS by airless spray. M.Levart, B.Thiebaut, J.Vedel (Ecole Nationale Superieure de Chimie de Paris, Paris, France).
Int. J. Sol. Energy (Switzerland), vol.1, no.6, p.451-7 (1983).
Airless spray consists of strongly compressing a liquid in a cylinder fitted with a nozzle. The droplets of liquid which are ejected can be pyrolized on a heated substrate. The technique was applied to the elaboration of CdS-Cu_2S photocells. A comparison with classic spray is given. There is an important decrease in energy consumption and spray time and the photocell properties are comparable. (6 refs.)

109892 Spectral dependencies of the efficiency of solar energy conversion by means of water photolysis. Zh.R.Panosyan, V.M.Arutyunyan, A.G.Sarkisyan, V.A.Meliksetyan, H.L.Margaryan, A.A.Poghosyan.
Izv. Akad. Nauk Arm. SSR Fiz. (USSR), vol.17, no.1, p.31-6 (1982). In Russian.
Spectral dependencies of the quantum efficiency of TiO_2 and *ZnO* semiconductor photoanodes obtained at the conversion of solar energy by means of the method of water photolysis were investigated. The influence of an external bias, of doping the photoanodes with donor and acceptor impurities as well as of photoanode surface states on the spectral dependencies of the efficiency is considered and a qualitative account for the measured dependencies is given. (7 refs.)

109893 Effect of pn coupling on open-circuit photovoltage decay in a silicon pn junction solar cell. S.K.Sharma, V.K.Tewary (Birla Inst. of Technol. & Sci., Pilani, India).
J. Phys. D (GB), vol.16, no.9, p.1741-7 (14 Sept. 1983).
A theory of open-circuit photovoltage decay in a pn junction solar cell is presented which accounts for the pn coupling, i.e. the coupling between the diffused layer and the base of the solar cell. The results have been analysed in some detail which show how the voltage decay is influenced by the various parameters of the diffused layer. It is found that the decay is sensitive to pn coupling in the initial stages, particularly in those solar cells in which a heavy doping of the diffused layer may have caused sufficient band-gap narrowing. A measurement of the voltage decay in the initial stages can therefore yield the parameters of the diffused layer in a solar cell. (18 refs.)

109894 The electrical characteristics of thin film Cu_xS-CdS solar cells and their dependence on the ambient atmosphere during annealing. F.J.Bryant, A.K.Hariri, S.Salkalachen, C.G.Scott (Dept. of Phys., Univ. of Hull, Hull, England).
J. Phys. D (GB), vol.16, no.9, p.1755-60 (14 Sept. 1983).
Changes in the electrical characteristics of polycrystalline Cu_xS-CdS solar cells have been studied following annealing treatments in air, vacuum and hydrogen, together with corresponding changes in the stoichiometry of the Cu_xS layer. Vacuum and hydrogen treatments have been found to produce very similar effects markedly different to the effects of air annealing. The results are consistent with previously reported Auger spectroscopy measurements which showed the Cu_xS layer and the Cu_xS-CdS interface structure to be very unstable when heated in air in comparison with the effect of annealing in either vacuum or hydrogen. (17 refs.)

109895 Application of infrared thermography to the study of the thermal behavior of solar-powered generators. A.Simo, F.Floret, J.P.David (Univ. d'Aix-Marseille, Marseille, France), G.Labrosse, G.Destobelleire.
Qualite Rev. Prat. Controle Ind. (France), vol.22, no.120, p.86-91 (April 1983). In French.
Photovoltaic modules are liable to malfunctioning caused by hot spots; investigation of these by superposition of monochromatic radiation on the solar illumination, or by lasers, is possible but only under laboratory conditions. Measurement of the temperature distribution over the surface of the module, and application of a numerical calculation procedure described in this paper, provide a means of estimation of the temperatures of the elements themselves. Whilst accurate measurements are not practicable, the qualitative information obtained provides a means of rapid location of any defective element. (9 refs.) *N.C.*

109896 A modified shifting approximation for homojunction single crystal silicon solar cells. S.Vasile, F.Caldararu (Sci. Res. & Technol. Engng. Center for Semiconductors, Bucharest, Rumania).
Rev. Roum. Phys. (Rumania), vol.28, no.6, p.533-40 (1983).
The shifting approximation in solar cells states that the current-voltage characteristic is obtained from a dark I-V characteristic shifted downward by light generated current. Some methods used for the determination of solar cell parameters, based on the shifting approximation, are reviewed. There are some contradictory results referring to the silicon solar cell series resistance. The failure of the shifting approximation for a single crystal silicon solar cell is considered to be an input idea and, as a result, an experimental procedure for the determination of solar cell parameters is developed, without using the shifting approximation. An experimental proof of the light modulated junction parameters is provided. A modified shifting approximation is proposed. (10 refs.)

109897 Formation of nickel and palladium silicides by a short-pulse light-flash and its application in the metallization of solar cells. Juh Tzeng Lue (Dept. of Phys., Nat. Tsing Hua Univ. Hsinchu, Taiwan).
Solid-State Electron. (GB), vol.26, no.8, p.787-93 (Aug. 1983).
Silicon-rich compounds which are not producible by conventional furnace annealing can be formed by a short-pulse light-flash. Inhomogeneous reaction, cellular solidification and small diffusion depth of the metal atoms, resulting from the fast liquid-to-solid quench process, are characteristic of flash-lamp induced silicides. Electroless-nickel plated solar cells after sintering with a light-flash show comparable I-V characteristics with those obtained by the expensive Ti-Pd-Ag alloy method. (11 refs.)

109898 Plasma-enhanced CVD silicon nitride antireflection coatings for solar cells. C.C.Johnson, T.Wydeven (Ames Res. Center, NASA, Moffett Field, CA, USA), K.Donohoe.
Sol. Energy (USA), vol.31, no.4, p.355-8 (1983).
Multilayer plasma-enhanced chemical vapor deposition (PECVD) silicon nitride antireflection coatings were deposited on space quality silicon solar cells. Preliminary experiments indicated that multilayer coatings decreased the total reflectance of polished silicon from 35 per cent to less than 3 per cent over the spectral range 0.4-1.0 μm. The solar cell energy conversion efficiency was increased from an average of 8.84 per cent to an average of 12.63 per cent. (9 refs.)

109899 Optimization of static or quasi-static photovoltaic installations. A.Lopez Pinto, R.Dios (ETSIA, Univ. de Cordoba, Cordoba, Spain), A.Luque.
Sol. Energy (USA), vol.31, no.4, p.393-404 (1983).
The paper presents a computer calculation method which permits the determination of the elevation angle with respect to the equator for each position adopted by a quasi-static collector, the determination of the dates for the seasonal changes in elevation, and also the calculation of the minimum collector area to be installed to achieve the maximum agreement between the curves of energy needed and collected with no seasonal accumulation. This procedure has been used in three typical rural applications: a rural home, a dairy farm with mechanical milking and milk refrigeration, and a watering sprinkler system for 1 Ha of prairie land, all located in the Cordoba province of Spain. (18 refs.)

109900 Transparent conducting tin oxide films for application in heterojunction solar cells. N.S.Murty, S.R.Jawalekar (Dept. of Electrical Engng., Indian Inst. of Technol., Bombay, India).
Vac News (India), vol.13, no.2, p.11-14 (June 1982). [received: Aug. 1983]
The authors report the structural, electrical and optical properties of tin oxide films deposited by oxidation of stannous chloride. The objective of the work is to deposit SnO_2 films possessing low resistivity and high optical transmission for their future applications in heterojunction solar cells. The summary of the results presented is based on extensive studies reported earlier. (8 refs.)

86.30K Photoelectrochemical conversion

109901 Photovoltage generation in the solid phenosafranine-EDTA sandwich cell. K.K.Rohatgi-Mukherjee, M.Roy, B.B.Bhowmik (Phys. Chem. Lab., Jadavpur Univ., Calcutta, India).
Sol. Energy (USA), vol.31, no.4, p.417-19 (1983).
Recently, the authors have reported a photovoltage of 615 mV at 25°C of a redox system consisting of phenosafranine and EDTA in aqueous medium, and this value increases with increasing temperature attaining 870 mV at 49°C [1978, 1983]. In consideration of the possibility of introducing this photogalvanic cell commercially, this system has been studied in the solid polycrystalline state in a sandwich cell using illuminated semiconductor (SnO_2) and dark metal (platinum foil) electrodes. The results are reported. (8 refs.)

109902 Analysis of transverse edge effect of linear induction pump with electrically conducting side walls. S.Tado, S.Kamiyama (Inst. of High Speed Mech., Tohoku Univ., Sendai, Japan).
J. Nucl. Sci. & Technol. (Japan), vol.20, no.5, p.279-88 (May 1983).
An analytical study is made of transverse edge effect on the flow characteristics and performance of a linear induction pump by taking into account both effects of a nonuniform velocity distribution across the duct width and an electrical conductivity of the side-walls installed in a fringing magnetic flux region. Equation of fluid motion and Maxwell's equations with a thin-plate approximation are simultaneously solved using a method of successive approximation, and the effects of the side-wall's conductivity on the distributions of magnetic field and flow velocity are determined. Pump performances such as mechanical and electrical powers, conversion efficiency and head-flow curves are also obtained. It is clearly shown that the secondary current in the fluid and hence the pump performance are significantly influenced by the side-wall's conductivity. It is also shown that the nonuniformity of the velocity distribution causes a reduction in the equivalent conductivity of the secondary which is significant in the case of low side-wall's conductivity. (16 refs.)

86.30M Thermoelectric conversion

109903 A calculation method for batteries of thermoemission converters. M.A.Mendel'baum, A.P.Savinov, V.V.Sinyavskii.
Power Eng. (J. Acad. Sci. USSR) (USA), vol.20, no.6, p.113-20 (1982). Translation of: *Izv. Akad. Nauk SSSR Energ. & Transp.*, vol.20, no.6, p.140-7 (1982).
A numerical method is proposed for calculating the characteristics of thermo-emission-converter batteries (TCB) with series-parallel connection of the elements. The method is based on successive solution of equations describing the thermal and electrical processes. The calculation algorithm has been realized as a BESM-Algol program. The possibilities of the program are indicated, calculation of the characteristics of a specific type of TCB serving as an example. The nature of the change in the thermal and electrical characteristics resulting from fluctuations in thermal power and electrical load as well as interruption of the internal electric circuit is demonstrated. (11 refs.)

109904 Studies of a thermoelectric generator operating from tubular solar collectors. T.Durst, L.B.Harris, H.J.Goldsmid.
Sol. Energy (USA), vol.31, no.4, p.421-5 (1983).
Solar energy conversion systems usually require storage of the energy that is produced. In this study the low voltage, high current characteristics of a thermoelectric generator were used to produce hydrogen gas in a practical demonstration of solar energy conversion and storage. Oil-filled evacuated glass tubes were used as concentrators of solar heat, the oil circulating through the system being the medium for transferring heat. The system had four main components: (1) A solar collector consisting of seven evacuated glass tubes. (2) A thermoelectric generator. (3) A centrifugal pump, oil reservoir, and associated piping to circulate the hot oil. (4) An electrolytic hydrogen gas generator. The results obtained and conclusions reached are presented. 109905 The measurement of light transmission through an irradiated fluidised bed. L.Rizzuti (Istituto di Ingegneria Chimica, Univ. di Palermo, Palermo, Italy), P.L.Yue.
Chem. Eng. Sci. (GB), vol.38, no.8, p.1241-9 (1983).
The transmission of light through an irradiated fluidised bed with vertical flat walls containing catalytic particles has been experimentally studied. The amount of light transmitted through the reactor was measured at different levels by a photocell. The experimental variables studied included: (i) gas flow rate, varying from 2 to more than 10 times that required for minimum fluidisation; (ii) mean particle size, ranging from 0.138 to 0.275 mm; and (iii) internal bed thickness from 2.1 to 4.9 mm. The effect of the reflectance of the particles was also examined. The amount of light transmitted through a flat fluidised bed is low. The average transmitted light has been satisfactorily correlated with average bubble voidage of the bed, particle diameter and bed thickness. (13 refs.)

109906 Photochemical solar collector for the photoassisted reduction of aqueous carbon dioxide. M.Halmann, M.Ulman, B.Aurian-Blajeni (Isotope Dept., Weizmann Inst. of Sci., Rehovot, Israel).
Sol. Energy (USA), vol.31, no.4, p.429-31 (1983).
Solar collectors are widely used for converting the radiation of sunlight into useable heat, particularly for heating water or buildings. The present study describes a modified solar collector, which uses the ultraviolet and visible spectrum of solar radiation for carrying out photochemical energy storage, by the photosynthetic conversion of carbon dioxide and water over photoactive materials into useful organic compounds, particularly formic acid, formaldehyde and methanol. This photoassisted reaction was previously carried out in several laboratory studies with artificial light. The purpose of testing these reactions in actual sunlight is to obtain direct values of solar to chemical energy conversion efficiencies, without the assumptions inherent in using artificial light sources. The photoactive agents tested are all oxide semiconductors, used as powdered polycrystalline materials. (9 refs.)

86.30R Thermal energy conversion (heat engines and heat pumps)

109907 The performance of heat pumps in service—comparison of a computer model with a real installation. J.Rosell, R.Morgan, J.T.McMullan (School of Phys. Sci., New Univ. of Ulster, Coleraine, N Ireland).
Int. J. Energy Res. (GB), vol.7, no.3, p.227-40 (July-Sept. 1983).
A comparison is made between a computer model which was developed in an earlier paper and experimental results in which a heat pump was used to heat a house during the heating season 1978-1979. The heat pump used was an air-to-water machine, and it is found that the radiator temperature in the experiment varies according to the heat demand of the house because of the effect of thermal inertia of the water and other thermal masses in the heat transfer system. The computer model simulates this effect, using hourly weather data to calculate the heat demand of the house and assuming that the radiators run at the temperature necessary to supply the heat demand during each hour. The model also calculates the coefficient of performance of the heat pump, and hence calculates the running cost in kilowatt-hours for each hour. The calculated running cost is compared with daily readings of kilowatt-hour meters. It is found that the comparison is very accurate during normal operation of the heat pump, with an accuracy of better than 1 per cent over a period of four months of the heating season, although the accuracy is not always quite so good. A comparison is also made between hourly calculated radiator temperatures and continuous recordings of flow and return temperatures. The comparison in this case is satisfactory, but there is a time lag due to the effect of thermal inertia of the building fabric which the computer model is not intended to simulate. (5 refs.)

109908 Limiting performance of vapour compression heat pumps for heating fluids. C.G.Carrington, T.C.Knopp (Dept. of Phys., Univ. of Otago, Dunedin, New Zealand).
Int. J. Energy Res. (GB), vol.7, no.3, p.255-64 (July-Sept. 1983).
When a vapour compression heat pump is used to heat a fluid over a range of temperatures the refrigerant cycle may be fundamentally different from a standard Rankine cycle which operates only between isothermal reservoirs. This paper considers two strategies for heating fluids: in one approach the fluid is heated in a single pass condenser; in the other the body of fluid is kept fully mixed at all stages of the heating process. An isothermal source reservoir is assumed and the performance of nine common refrigerants is examined. In the ideal limit the mixed fluid process has a higher COP than

the single pass method. But in practice there is likely to be no clear advantage in using a fully mixed sink fluid, especially where the temperature lift is greater than 50°C. The single pass heating process has an advantage under these conditions that lower peak condensing temperatures may generally be achieved than for the mixed fluid heating process. (9 refs.)

Regulation of daily refrigerating-capacity schedule of a solar absorption refrigerating unit ....See Entry 109911

86.30S Photothermal conversion

109909 Tests of a module for a parabolocylindrical solar installation. B.V.Tarnizhevskii, I.I.Kokhova, S.N.Aliev, V.A.Samoilov, S.F.Ergashev (Krzhizhanovskii Sci. Res. Inst. of Power Engng., USSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.21-6 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.19-23 (1982). [received: Aug. 1983]
Describes tests of the operating conditions of a module for a parabolocylindrical solar installation with a heat-pipe heat absorber at operating temperatures up to 300°C. The basic element of the installation, namely the parabolocylindrical reflector, has dimensions $L \times B = 5000 \times 2000$ mm, a focal length $f = 850$ mm, and an aperture angle $2\alpha = 120°$. The reflecting surface of the concentrator is made of electrically polished aluminum sheet 1 mm thick, with a protective oxide film 10-12 μm thick. The integral coefficient of reflection of sunlight for the aluminum mirror surface $R_m = 0.79$-0.8. (3 refs.)

109910 Method of making heat-engineering calculations for a passive solar heating system (nonsteady conditions). R.R.Avezov, K.B.Babakulov (S.V. Starodubtsev Phys. Tech. Inst., Acad. of Sci., Uzbek SSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.46-52 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.39-44 (1982). [received: Aug. 1983]
The authors set up and solve the balance equations that describe the thermal state of individual elements of a passive solar heating system with allowance for the nonsteady nature of solar radiation and the outer air temperature. (2 refs.)

109911 Regulation of daily refrigerating-capacity schedule of a solar absorption refrigerating unit. O.Klyshchaeva, A.Kakabaev, G.Redzhepov (Solntse Sci. & Industrial Assoc., Acad. of Sci., Ashkhabad, Turkman SSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.53-60 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.44-50 (1982). [received: Aug. 1983]
Considers various SARU operating conditions that make it possible to extend operation into the period in which no sunshine is present. For this purpose, for the corresponding modes of SARU operation, the authors establish a relationship for water content of the solution in the system that enables them to determine the refrigerating-capacity schedule. The resultant relationships are used to obtain graphs for the characteristic operating conditions of the SARU. (4 refs.)

109912 Effect of angle of inclination on the operating efficiency of a solar radiative drying installation. G.G.Umarov, B.M.Nabikhanov, Z.Tairov (Starodubtsev Physicotech. Inst., Acad. of Sci., Uzbek SSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.71-3 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.58-60 (1982). [received: Aug. 1983]
The article offers analytic calculations of the effect of the angle of inclination on the operating efficiency. (1 ref.)

109913 On the improvement of solar heating and cooling systems. Yu.K.Rashidov (Tashkent Zonal Sci. Res. Inst. for Experimental Design of Dwellings & Public Buildings, USSR).
Appl. Sol. Energy (USA), vol.18, no.5, p.85-9 (1982). Translation of: *Geliotekhnika (USSR)*, vol.18, no.5, p.68-73 (1982). [received: Aug. 1983]
To simplify solar heating and cooling systems, the author proposes the use of organized hydrothermal processes in their elements. Definitions and a classification of such processes are offered. (5 refs.)

109914 Simulation of behaviour of a drying system for grain. M.Hasnaoui (Lab. de Thermodynamique et Energetique, Univ. de Perpignan, Perpignan, France), G.le Palec, M.Daguenet.
Int. J. Sol. Energy (Switzerland), vol.1, no.6, p.431-40 (1983). In French.
The behavior of a maize pile that is subjected to double influence of the radiation flux and the forced convection of warm air is studied as a function of principal parameters of the system. Two possibilities of the recycling of the air in the dryer are considered. Thus, it proves that recycling is interesting while it is carried out across the collector (indirect recycling) since it permits to economize the dispensed energy in the system and reduces the drying time. If the recycling is direct, in other words if the recycled air is sent directly across the grains, there is a limit as regards the percentage of the recycled air. The improvement of the drying performances where the bed of grains is subjected simultaneously to a warm air current and direct solar radiation is not meaningful and is undue for operating such processes. The theoretical model established permits one to know the system's response due to the variation of the parameters such as the flow rate, the temperature of the entering air and the collector surface; and so can help the conception of the solar drying for cereals. (6 refs.)

109915 Reduction of surface mixing in solar ponds by floating rings. A.Akbarzadeh, R.W.G.MacDonald, Y.F.Wang (Dept. of Mech. Engng., Univ. of Melbourne, Melbourne, Australia).
Sol. Energy (USA), vol.31, no.4, p.377-80 (1983).
The phenomenon of mixing in the top region of solar ponds is investigated. The factors causing this problem are described. Effects of wind in creating the top layer convective zone are discussed. Necessary formulas for determination of amplitude and frequency of the waves generated by the winds in terms of wind velocity and fetch length are given. Also the problem of wind driven currents in solar ponds is discussed. The idea of small circular floating rings as wave suppressors is introduced and their effectiveness in decreasing the thickness of the top convective zone is discussed. It has been found that the floating ring wave suppressors can successfully decrease the depth of the top mixing layer in solar ponds. (7 refs.)

109916 Orientational relationships for optically non-symmetric solar collectors. W.R.McIntire, K.A.Reed (Solar Energy Group, Argonne Nat. Lab., Argonne, IL, USA).
Sol. Energy (USA), vol.31, no.4, p.405-10 (1983).
More details of collector orientations and incidence angle modifiers are required to specify the instantaneous optical efficiencies of optically non-symmetric solar collectors, such as those using nonimaging concentrators, than to specify the efficiencies of symmetric collectors such as flat plates. In the paper, expressions are presented for the projected incidence angles necessary for evaluating the instantaneous optical efficiencies of non-symmetric collectors. These projected angles are also used when a nearly biaxial incidence angle modifier is approximated by the product of two single-axis incidence angle modifiers. In addition, relationships for incidence angles onto an absorber tube are developed. These differ from the angle onto a cover glazing, and they effect the absorptance of the tube's coating and the transmittance of a cover tube as used in tubular evacuated collectors. (2 refs.)

109917 Prediction of heat losses by conduction and radiation from total heat loss data for degraded evacuated collectors. S.P.Chow, D.R.Mills, G.L.Harding (School of Phys., Univ. of Sydney, Sydney, NSW, Australia).
Sol. Energy (USA), vol.31, no.4, p.433-5 (1983).
The authors discuss a non-destructive means of evaluating the heat loss by radiation and conduction from the measured total heat loss for evacuated collectors containing a particular selective surface. They show that the emittance-temperature relation for various types of selective surface can be modelled by a simple empirical formula. This formula can then be used to model the radiative heat loss in a collector. If it is assumed that the conduction loss Q_c varies linearly with temperature difference between absorber and glass envelope, $(T_1 - T_2)$, computer analysis of the measured total heat loss Q_T allows determination of the constants in the empirical formula. The accuracy of results produced by this method has been investigated for 5 degraded collectors (which contain various quantities of gas) for which radiative heat loss Q_R and Q_c have been determined experimentally. 109919 Test procedures for heat storages for solar heating systems. S.Furbo (Thermal Insulation Lab., Tech. Univ. of Denmark, Lyngby, Denmark).
Int. J. Sol. Energy (Switzerland), vol.1, no.6, p.419-29 (1983).
The Danish Government supports producers of systems for renewable energy sources (solar, wind, biomass). At present the consumer will receive 30% of the investments in the installed solar heating system. In order to participate in this arrangement it is required of the producers that the components of their solar heating systems are tested. The heat storages are tested at the Thermal Insulation Laboratory at the Technical University of Denmark. Tests of marketed heat storages for solar heating systems for domestic hot water supply started in 1979, and since then the test procedures have been changed continuously according to the experience gained. The test procedure in use now and some of the experiences gained are described. (no refs.)

109920 Status of the cadmium thermoelectrochemical hydrogen cycle. T.Whaley, B.Yudow, R.Remick, J.Pangborn, A.Sammells (Inst. of Gas Technol., IIT Center, Chicago, IL, USA).
Int. J. Hydrogen Energy (GB), vol.8, no.10, p.767-71 (1983).
The three-step cadmium thermoelectrochemical water-splitting cycle produces hydrogen by an electrochemical reaction of water with an anode of cadmium metal, which is regenerated by the thermochemical decomposition of by-product cadmium oxide at temperatures of 1200°C and higher. Work on the electrochemical step has centered on the removal of the passivating layer of cadmium hydroxide that forms on the cadmium metal anode. The high-temperature thermochemical decomposition of cadmium oxide has been carried out successfully in a solar furnace. (5 refs.)

109921 Technological aspects of sulfur dioxide depolarized electrolysis for hydrogen production. P.W.T.Lu (Advanced Energy Systems Div., Westinghouse Electric Corp., Pittsburgh, PA, USA).
Int. J. Hydrogen Energy (GB), vol.8, no.10, p.773-81 (1983).
Significant advancements in the SO_2-depolarized electrolysis technology have been obtained through a series of technical improvements in the electrode structure and cell configurations. Using carbon-supported platinum catalyst of loading 1 mg/cm^2, the currently achievable cell potentials are 680 and 910 mV at 200 and 400 mA/cm^2, respectively, in 50 w/o aqueous H_2SO_4 solution at 75°C and atmospheric pressure. To reduce further the electrical energy input for an SO_2-depolarized cell, major experimental efforts will be made to investigate the performance characteristics of pressurized electrolyzers. An advanced concept, using a solid oxide electrolyte, has been proposed for the electrochemical oxidation of gas-phase SO_2. Due to the elimination of aqueous electrolyte, this novel sulfur-based cycle is expected to result in a higher cycle efficiency and a lower corrosion environment than the conventional sulfur cycle hydrogen product process. (11 refs.)

109922 Hydrogen absorption in Mg-Ni-Fe alloys. D.Lupu, A.Biris, E.Indrea, N.Aldea, R.V.Bucur (Inst. of Isotopic & Molecular Technol., Cluj-Napoca, Rumania), M.Morariu.
Int. J. Hydrogen Energy (GB), vol.8, no.10, p.797-9 (1983).
The hydrogenation properties of the alloys of overall formula $Mg_2Ni_{1-x}Fe_x$ ($x \leq 0.37$) have been studied. In this range of composition multi-phase alloys were obtained containing Mg_2Ni, Mg and more or less finely dispersed Fe in different coordination as proved by the EXAFS technique and Mossbauer spectroscopy. There is no significant substitution of Ni by Fe atoms in the Mg_2Ni lattice. Two or three plateau-pressures are observed on the pressure-composition isotherms of the hydrides with the heats of formation in the range −18.4 to 20.4 kcal/mol H_2 (−77 to −85.4 kJ/mol H_2). The hydrides of the Fe containing alloys show higher desorption rates of hydrogen compared to the pure Mg_2Ni hydride. (17 refs.)

109923 Hydrogen sorption performance of pure magnesium during continued cycling. B.Vigeholm, J.Kjoller, B.Larsen, A.S.Pedersen (Metall. Dept., Riso Nat. Lab., Roskilde, Denmark).
Int. J. Hydrogen Energy (GB), vol.8, no.10, p.809-17 (1983).
Preliminary investigations of the hydrogen absorption-desorption by commercially pure magnesium powder under continuous operation show little or no reduction in hydrogen capacity up to 70 cycles and high temperature exposure exceeding 1200 h. Absorption was studied at 260°-425°C and hydrogen pres-

sures up to 2.0 MPa above equilibrium. Desorption was with a few exceptions done at 400°C at hydrogen pressures below 150 kPa. For practical application the hydrogen exchange may be limited to 75-90% of the complete metal to stoichiometric hydride reaction. A change of the macroscopic structure of the powder into a highly porous, sintered agglomerate did not reduce the hydrogen capacity or the reaction rate. Although this change in structure caused no deterioration of the cycling performance a further development may not be acceptable. For observation over a much larger number of cyclings a fully automated, triple line cycling facility permitting simultaneous testing under different conditions has been constructed. (5 refs.)

109924 Hydrogen safety manual. W.Balthasar, J.P.Schodel.
Report EUR 8396 EN, Comm. European Communities, Luxembourg (1983), x+522 pp. Contract 256-77 EH NL.
The objective of this manual is to facilitate safe design and operation of hydrogen handling systems. A potential user of this manual will find all necessary regulations, codes and practices needed to observe when designing or operating a hydrogen handling system. A detailed discussion for special considerations and subjects on safety are also presented. (150 refs.)

109925 Morphological, sedimentological and chemical aspects of the sediments in the Gulf of Cagliari (Sardinia). A.Contu (Istituto di Igiene, Univ. di Cagliari, Cagliari, Italy), P.Mulas, G.Sarritzu, M.Schintu, A.Ulzega.
Boll. Oceanol. Teor. & Appl. (Italy), vol.1, no.3, p.205-13 (July 1983).
In southern Sardinia, the Gulf of Cagliari is affected by contamination due to the particular location of the urban agglomerates and industrial plants. The untreated sewage of the town of Cagliari and the suburban agglomerates converge, through the port, directly to the western side of the Gulf, between Capo S. Elia and Punta Zavorra. The sludges of a lot of industries are discharged near the port and in the wide lagoon of Santa Gilla as well. The sediments of the Gulf of Cagliari have been collected from a few stations chosen for their morphological and sedimentological characteristics of the sea bottom, in order to survey their chemical features. The levels of some metals (Pb, Hg, Cu, Cr, Zn, Fe), the organic compounds and oils accumulated on sediments are determined. (17 refs.)

109926 Dispersion and sedimentation of industrial waste of bauxite, blendes, fluorites and phosphorites dumped in the Gulf of Venice, Italy. A.Brambati, R.Marocco (Istituto di Geologia e Paleontologia, Univ. di Trieste, Trieste, Italy).
Boll. Oceanol. Teor. & Appl. (Italy), vol.1, no.3, p.215-24 (July 1983).
Reports the results of the sedimentological investigation carried out in August 1974 in the marine area of the Gulf of Venice involved in the discharge of industrial waste of bauxite, blendes, fluorites and phosphorites from Porto Marghera (Venice). On the basis of chemical and grain size analyses carried out on 35 samples of sediment collected in the Gulf of Venice, it is possible to identify the marine area involved in the discharge and define the modifications brought about on the sediments in the Gulf. (14 refs.)

109927 Anthropogenic tritium in South Atlantic bottom water. W.J.Jenkins, D.E.Lott, M.W.Pratt, R.D.Boudreau (Woods Hole Oceanographic Instn., Woods Hole, MA, USA).
Nature (GB), vol.305, no.5929, p.45-6 (1 Sept. 1983).
By increasing sample size and altering sample handling techniques, the authors have extended the tritium detection limit by more than an order of magnitude and have detected what is believed to be man-made tritium in Antartic bottom water at about 40°S in the western South Atlantic. (9 refs.)

109928 Fly-ash particles intercepted in the deep Sargasso Sea. W.G.Deuser (Woods Hole Oceanographic Instn., Woods Hole, MA, USA), K.Emeis, V.Ittekkot, E.T.Degens.
Nature (GB), vol.305, no.5931, p.216-18 (15 Sept. 1983).
Results of a continuing series of sequential sediment-trap deployments in the Sargasso Sea, covering 5 yr, suggest that an efficient mechanism exists for the removal of both biogenic and abiogenic particles from the surface layers of the ocean and for their rapid transfer to great depth. The occurrence of fly-ash particles in material collected in that experiment is reported. Available evidence indicates that these particles were carried by winds from their sources, probably located in North America, to the Sargasso Sea and subsequently transported to deep water as components of faecal pellets or other organic aggregates. (18 refs.)

109929 Anthropogenic chlorofluoromethanes in the Greenland and Norwegian Seas. J.L.Bullister, R.F.Weiss (Scripps Instn. of Oceanography, Univ. of California, San Diego, CA, USA).
Science (USA), vol.221, no.4607, p.265-7 (15 July 1983).
The concentrations of two industrially produced chlorofluoromethanes, CCl_3F(F-11) and CCl_2F_2(F-12), have been measured in the water column and in the marine atmosphere of the Greenland and Norwegian seas. Measurable concentrations of these two chlorofluoromethanes have penetrated to the deep basins of both of these regions, and the general characteristics of their vertical distributions are discussed. The data are fitted to a time-dependent box model based on deep convective mixing in the Greenland Sea and lateral exchange between the deep basins. The model calculations for the two chlorofluoromethanes in the Greenland Sea give similar results, with a time scale for deep convection of about 40 years. (15 refs.)

109930 Neptunium and americium speciation in selected basalt, granite, shale, and tuff ground waters. J.M.Cleveland, T.F.Rees, K.L.Nash (US Geological Survey, Denver, CO, USA).
Science (USA), vol.221, no.4607, p.271-3 (15 July 1983).
Neptunium and americium are relatively insoluble in ground waters containing high sulfate concentrations, particularly at 90°C. the insoluble neptunium species is Np(IV); hence reducing waters should enhance its formation. Americium can exist only in the trivalent state under these conditions, and its solubility also should be representative of that of curium. (8 refs.)

109931 Optical emission from photoexcitation of aerosol particles produced by reaction of ozone with 1,3-butadiene. R.L.Day, L.C.Lee (Dept. of Electrical & Computer Engng., San Diego State Univ., San Diego, CA, USA).
Appl. Opt. (USA), vol.22, no.17, p.2546-50 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
Aerosol particles produced from the ozone and 1,3-butadiene reaction are excited by ultraviolet radiation. Optical emissions from the photoexcited aerosol particles are observed in the 300-800 nm region. The emission intensities are measured at various gas concentrations and reaction times. The aerosol formation mechanisms and the sources responsible for optical emissions are investigated. It is suggested that the small radicals adsorbed on the surface of aerosol particles are simultaneously desorbed and excited by UV photons, and the excited radicals subsequently give optical emissions. (17 refs.)

109932 An air pollution analytic transport model admitting the surface and inversion layer effect. D.L.Yordanov, K.G.Ganev, M.P.Kolarova (Geophys. Inst., Bulgarian Acad. of Sci., Sofia, Bulgaria).
C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.5, p.627-30 (1983).
When investigating air pollution, use is often made of the Lagrange method of a series of puffs with a Gauss distribution of the concentration in a horizontal direction, while along the vertical the semiempirical diffusion equation $\partial q/\partial t = K\partial^2 q/\partial z^2$ (1) is solved, in which q is the pollution concentration and K is the coefficient of vertical turbulent exchange. A study is made of the solution of equation (1) the layer $a \geq z \geq h$, where h is the height of the surface layer (SL) and a is the height of inversion. The diffusion of the admixtures in SL is estimated parametrically, on the assumption that sources may exist in SL. (3 refs.)

109933 Calculation of the concentration field of radioactive admixtures. T.Ts.Todorov (Geophys. Inst., Bulgarian Acad. of Sci., Sofia, Bulgaria), G.D.Djolov, D.E.Sirakov.
C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.5, p.635-8 (1983).
Meteorology plays an essential role in protecting the environment from radiation. Its theoretical and practical instruments are widely used in locating, planning, building and commissioning atomic power plants, establishing their normal and average operational conditions, in closing them after expiration of the performance term, and in the treatment of radioactive waste as well as with experimental reactor accelerators of charged particles and thermonuclear reactors. The high requirements for safeguarding those at work in atomic power plants and the biosphere in the adjacent regions from radiation fall-out call for more exact modern methods of calculating the concentration field produced by sources of radioactive admixtures. Estimates of the level of the environment's radioactive pollution have been obtained by means of familiar formulas of the Gaussian type. The main shortcomings in this approach are: assumption of stationarity of the process, use of formulas for a continuous point source in case of finite release time, neglect of the interaction between radioactive pollutant and underlying surface as well as the effect of inversion layers. These shortcomings are by and large eliminated by the approach proposed by the authors. They consider the most interesting practical case: accident in the atomic reactor. (2 refs.)

109934 Air Force Rocket Propulsion Laboratory plume program: activities and plans. P.M.Saatzer (USAF Rocket Propulsion Lab., Edwards Air Force Base, CA, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.366, p.148-56 (1983). (Modern Utilization of Infrared Technology VIII, San Diego, CA, USA, 26-27 Aug. 1982).
Presents the status of current phenomenological models for high altitude plume signatures. Major limitations are discussed and R&D efforts to remove these limitations are reviewed. These R&D projects are placed in two categories: fundamental properties and methodology development. Projects to

obtain fundamental properties include: theoretical predictions/measurements of collisional excitation cross sections and vibrational relaxation rates, and measurements of physical/chemical properties of propellant aerosols. Methodology development include a composite high altitude signature model and an aerosol radiation model. (22 refs.)

109935 Transition flow effects on plume radiation. J.B.Elgin (Spectral Sci. Inc., Burlington, MA, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.366, p.180-7 (1983). (Modern Utilization of Infrared Technology VIII, San Diego, CA, USA, 26-27 Aug. 1982).
A calculational comparison of a free molecular plume code (HAPAIR: High Altitude Plume-Atmosphere Interaction Radiation) and a Monte-Carlo Plume Code (TRAMP: Transitional and Rarefied Axisymmetric Monte-Carlo Plume) is made for selected sequence of cases going from a free molecular ($K_n=15$) to a high transitional ($K_n=0.07$) flow regime. Results are presented which document the breakdown of free molecular flow assumptions in the transition regime and show the effect on the critical physical processes responsible for plume emission. (9 refs.)

109936 Air pollution. N.Lentin (Maharashtra State Water & Air Pollution Control Labs., Maharashtra, India).
Instrum. India, p.9-14 (July-Aug. 1982). [received: Aug. 1983]
Discusses legal problems encountered in dealing with air pollution. Standards applicable in India are compared with those in the United Kingdom and United States. (no refs.)

109937 Estimate of radon-222 concentrations in rainclouds from radioactivity of rainwater observed at ground level. S.Minato (Government Industrial Res. Inst., Nagoya, Japan).
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.199-207 (1983).
A time-independent model is presented which predicts the short-lived radon daughter activity of rainwater at ground level for unit concentration of radon (^{222}Rn) in cloud. The model incorporates the physical processes of diffusive attachment of radon daughters and impact collection for cloud droplets by raindrops. It also includes consideration of cloud droplet and raindrop size spectra. It is concluded from the results from the model that the specific activity of rainwater is not affected very much by aerosol concentration, liquid water content, average radius of raindrops and height of cloud base but is affected markedly by rainfall rate. The radon concentrations in the rainclouds are estimated from the comparison between calculation and near-ground observations carried out for a period of almost 3 years. (14 refs.)

109938 Long-range transport of air pollution. F.B.Smith (Meteorological Office, Bracknell, England).
Meteorol. Mag. (GB), vol.112, no.1333, p.237-44 (Aug. 1983).
A general review is given of the known facts on the long-range transport of air pollution and its influence on 'acid rain' and of the present state of theoretical and practical investigation of the various problems involved. These include the nature of emissions, the amount of local deposition, the estimation of trajectories and lifetimes of airborne pollutants and their chemistry, relative amounts of dry and wet deposition, and background concentration. An account is given of computer modelling and observational studies being carried out by the Meteorological Office and of possible future developments. (8 refs.)

109939 Is there any chlorine monoxide in the stratosphere?. M.J.Mumma, J.D.Rogers, T.Kostiuk, D.Deming, J.J.Hillman, D.Zipoy (Infrared & Radio Astron. Branch, NASA Goddard Space Flight Center, Greenbelt, MD, USA).
Science (USA), vol.221, no.4607, p.268-71 (15 July 1983).
A ground-based search for stratospheric chlorine monoxide was carried out during May and October 1981 with an infrared heterodyne spectrometer in the solar absorption mode. Lines due to stratospheric nitric acid and tropospheric carbonyl sulfide were detected at about 0.2 percent absorptance levels, but the expected 0.1 percent lines of chlorine monoxide in this same region were not seen. Stratospheric chlorine monoxide is less abundant by at least a factor of 7 than is indicated by in situ measurements, and the upper limit for the integrated vertical column density of chlorine monoxide is 2.3×10^{13} molecules per square centimeter at the 95 percent confidence level. These results imply that the release of chlorofluorocarbons may be significantly less important for the destruction of stratospheric ozone than is currently thought. (32 refs.)

109940 Radioactive contamination of the surface boundary layer over the territory of the USSR in 1980. K.P.Makhon'ko, V.P.Martynenko, V.B.Chumichev, F.A.Rabotnova (Inst. of Experimental Meteorology, USSR).
Sov. Meteorol. & Hydrol. (USA), no.4, p.30-4 (1982). Translation of: *Meteorol. & Gidrol. (USSR)*, no.4, p.38-43 (1982).
The pattern of radioactive contamination of the surface boundary layer over the USSR in 1980 by nuclear explosion products is investigated. A comparative seasonal variation of the concentration of long-lived beta activity in individual years during the past five years is given. It is shown that radioactive contamination of the surface boundary layer in the USSR was at a very low level up to October 1980. A nuclear explosion in China on 16 October 1980 is discussed. (5 refs.)

109941 Critical confrontation of standard and more sophisticated methods for modelling the dispersion in air of heavy gas clouds; Evaluation and illustration of the intrinsic limitations of both categories. M.L.Riethmuller.
Report EUR 8423 EN, Comm. European Communities, Luxembourg (1983), 48 pp.
An attempt is made to perform a critical confrontation of the sophisticated models and the more standard ones. In each of these approaches, the essential feature responsible for the quality of the prediction is put in evidence. As an example of a K-model, the VKI code is described and used to illustrate the potential of this type of approach. The examples chosen: local differential heating of the ground, complex topography and variability in the wind direction, have shown that although K-models can deal with more complex situations, the uncertainty in the results is not lower than with other types of approaches. Results of predictions are given in terms of the probability of concentration in the case of variations in wind angle. It is shown that such an approach gives better indication of the ratio between mean and maximum concentrations. (13 refs.)

86.70J Noise

(see also 43.50 Noise, its effects and control)

109942 Noise—The deadline approaches. D.Woolley.
Interavia (Engl. Ed.) (Switzerland), vol.38, no.8, p.843-6 (Aug. 1983).
The author discusses noise limits imposed on aircraft in the United States and most European countries and looks at their implications for airlines. Compliance by various countries with Annex 16 Chapter 2 requirements of the Chicago Convention are tabulated. (no refs.)

109943 The Fifteenth Sir Richard Fairey Memorial Lecture: The quieter airport. N.J.Payne (British Airports Authority, Gatwick Airport, Gatwick, England).
J. Sound & Vib. (GB), vol.89, no.4, p.533-40 (22 Aug. 1983).
Aircraft noise as a social problem arrived less than a quarter of a century ago with the jets and has been a significant factor in airport planning and the development of air transport ever since. This paper explains how the industry has responded, with the introduction of operating techniques, and how Governments have introduced control, both designed to mitigate the effects of aircraft noise as far as possible, for people living near major airports. It shows that considerable success has been achieved and expresses the belief that as a result the worst is passed. The author also demonstrates that there are two sides to airport operation, noise nuisance, the main effects of which are confined to a relatively small area around the airport, is more than balanced by the environs of the airport and spread widely to the region in which it is located and ultimately to the nation as a whole.

109944 A new on-line estimation method of representative statistics of environmental random noise and vibration based on actual digital measurement. M.Ohta, S.Yamaguchi, Y.Mitani (Faculty of Engng., Hiroshima Univ., Higashihiroshima, Japan).
J. Acoust. Soc. Jpn. (Japan), vol.39, no.6, p.361-6 (June 1983). In Japanese.
It is obvious that a strictly stationary random process seldom exists in practical random phenomena such as urban noise and vibration. In the actual observation of random noise and vibration environment, it occurs very often that the level data of random noise and vibration are sampled in digital form at discrete time intervals by use of a sound level meter and vibration meter. Hereupon, the use of digital computer is essential for various types of statistical evaluation (e.g., median, mean value, variance, L_x, etc.) on the above random noise and vibration data. From these practical points of view, a unified expression of random noise and vibration level distribution which is applicable to arbitrary types of distribution form and nonstationary characteristics is newly established in this paper. More concretely, the explicit expression for the probability function for random noise and vibration level fluctuation is derived in the general form of a statistical orthogonal expansion series. Next, based on the above unified expression, a new algorithm estimating the representative statistics such as the L_x level is theoretically proposed, in the sequential form of on-line treatment. Finally, the actual effectiveness of the proposed on-line estimation method is experimentally confirmed by applying it to the experimentally observed road traffic noise data in the city. (6 refs.)

86.70L Measurement techniques in environmental science

109945 Determination of copper, cadmium and lead in seawater by atomic absorption spectrometry with electrothermal atomization. P.Scarazzato (Osservatorio Geofisico Sperimentale, Trieste, Italy).
Boll. Oceanol. Teor. & Appl. (Italy), vol.1, no.3, p.187-91 (July 1983).
A method is presented to determine copper, cadmium and lead in seawater by complexation with a mixture of ammonium pyrrolidinedithiocarbamate (APDC) and diethylammonium diethyl dithiocarbamate (DDDC), extraction

by carbon tetrachloride and subsequent analysis by flameless atomic absorption spectrometry. (8 refs.)

109946 Interferences in the radiochemical determination of ^{230}Th [in soil and water]. R.C.Burk, I.G.de Jong, D.R.Wiles (Dept. of Chem., Carleton Univ., Ottawa, Ontario, Canada).
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.81-5 (1983).
Earlier work on the coprecipitation of ^{230}Th and ^{234}Th with $BaSO_4$ has been confirmed and in particular the influence of other ions was investigated. Potassium ions, both in the solution and in the crystals, promote the coprecipitation, while polyvalent cations tend to prevent it. It is shown that increased concentration of K^+ causes a marked change in the $BaSO_4$ crystal form, with a concomitant increase in surface area. At the same time, the rate of exchange of $^{133}Ba^{2+}$ with the $BaSO_4$ surface is also increased. This can be roughly accounted for by the change in surface area. It is conjectured that an equilibrium occurs involving foreign cations in the lattice. (8 refs.)

109947 Enriched uranium as an activatable tracer in environmental research. E.S.Gladney, M.K.Wallwork-Barber, R.W.Ferenbaugh (Los Alamos Nat. Lab., Los Alamos, NM, USA).
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.209-12 (1983).
Isotopically enriched uranium and delayed neutron assay have been employed to study uranium dynamics within bee colonies. Preliminary data demonstrating the advantages of this activatable tracer method are presented. (14 refs.)

109948 Comparative determination of bromine and iodine in three air sampling media via instrumental thermal and epithermal neutron activation analysis. E.S.Gladney, W.A.Sedlacek (Los Alamos Nat. Lab., Los Alamos, NM, USA), W.W.Berg.
J. Radioanal. Chem. (Switzerland), vol.78, no.1, p.213-25 (1983).
A comparative determination of bromine and iodine in three distinct air sampling media by instrumental thermal and epithermal neutron activation analysis is presented. Open ocean air samples from the mid-Atlantic region were collected on ultra-pure nylon, Nuclepore, and activated charcoal substrates. The bromine and iodine content of each substrate was determined by both epithermal and thermal activation techniques. Good agreement was found within most thermal-epithermal pairs. Relative to the thermal activation procedure, the epithermal technique yields peak/background ratio improvements ranging from a factor of 1.30 to 9.5. Nylon substrates showed the smallest improvement at 1.30 and both Nuclepore and activated charcoal substrates showed improvement factors of 6.7 and 9.5 for bromine and iodine respectively. 87.10 GENERAL, THEORETICAL, AND MATHEMATICAL BIOPHYSICS

(inc. logic of biosystems, quantum biology, and relevant aspects of thermodynamics, information theory, cybernetics, and bionics)

109949 A computer model for the study of left ventricular wall contributions to the first heart sound. L.-G.Durand, R.Guardo (Inst. de Recherches Cliniques de Montreal, Montreal, Quebec, Canada).
Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.445-8
A numerical model of the heart-thorax acoustic system has been developed to study the transmission of intracardiac sounds through the cardiac muscles and the chest wall. The input signal to the system is the left ventricular PCG and the output is the apical PCG. Changes in the transmission path characteristics are modelled by varying the frequency response of an equivalent acoustic system throughout the cardiac cycle. The model is used to measure the influence of myocardial contractility on the left ventricular and thoracic first sounds, as well as the properties of the heart-thorax acoustic system. A method is described for determining the transfer and coherence functions of the system for each cardiac sound. The coherence function provides an estimate of the power contributed by each frequency component of the left ventricular sound to the total power of the apical sound. (5 refs.)

109950 Concentration (Co) dependence of the thermal stability of DNA duplexes. D.R.Bachvarov, I.G.Ivanov, G.G.Markov (Inst. of Molecular Biology, Bulgarian Acad. of Sci., Sofia, Bulgaria).
C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.5, p.667-70 (1983).
DNA reassociation is a widely used method to studying the evolutionary relationship between different organisms. This approach is especially advantageous for the taxonomy of prokaryotes where precise information derived from fossil records is not available. In a previous paper (1978) the authors showed that the thermal stability of the duplexes of a DNA giving mismatches upon reassociation under open experimental criterion strongly depends on Co*t* (Co is the concentration of single-stranded DNA and *t*—the time of incubation). The process of increase in the perfectness of the DNA duplexes accompanying the increase in Co*t* was termed 'maturation'. The present study aims to demonstrate that even these two parameters (Co and *t*) may affect the thermal stability of the DNA duplexes obtained upon reassociation to one and the same Co*t* value. (5 refs.)

109951 A new hypothesis on the mechanism of muscular contraction. N.S.Miroshnichenko (T.G. Shevchenko Kiev State Univ., Kiev, Ukrainian SSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.124-5
The basic idea of the proposed hypothesis on the contraction of cross-striated muscle is the screwlike motion of the thick protofibril inside the six hexagonally arranged thin protofibrils, like the movement of a screw and nut. The thick protofibril, the 'screw', rotates as a result of which the six thin protofibrils—the 'nut'—are wound onto the 'screw'. (7 refs.)

109952 An investigation of the interaction of liposomes with cytoplasmic brain proteins by small-angle X-ray scattering. N.I.Mishchenko, M.K.Malysheva, V.A.Zhukareva, A.F.Shryshevskii (T.G. Shevchenko Kiev State Univ., Kiev, Ukrainian SSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.168-71
For the experiments reported the authors used unoriented polydisperse liposomes composed of total cattle brain lipid, which were modified by soluble cytoplasmic proteins. Using small-angle X-ray scattering, the authors showed that integration of proteins with liposomes is accompanied by a change in the electron density profile of their wall. Hence, such a method can be used to investigate protein-lipid interactions. (12 refs.)

109953 Equilibrium species in cobalt(II) carbonic anhydrase. I.Bertini, G.Lanini, C.Luchinat (Inst. of General & Inorganic Chem., Univ. of Florence, Florence, Italy).
J. Am. Chem. Soc. (USA), vol.105, no.15, p.5116-18 (27 July 1983).
By measurement of the ^{1}H NMR T_1 values of the 4 H proton of the coordinated histidine-119 of cobalt(II)-substituted human carbonic anhydrase B and bovine carbonic anhydrase B as a function of pH, it is proposed that the coordination number around the cobalt(II) ion in bovine carbonic anhydrase B is always four, whereas it is largely five in human carbonic anhydrase B in the low pH limit. This hypothesis is consistent with the different spectral properties and pK_a values of the two isoenzymes. (22 refs.)

109954 Spectroscopic study of the interaction of 1-anilinonaphthalene-8-sulfonate and 2-toluidinoaphthalene-6-sulfonate with human blood plasma lipoproteins. V.I.Yuzhakov, S.El'Karadagi, O.V.Martsenyuk, L.V.Levshin, V.A.Tverdislov.
J. Appl. Spectrosc. (USA), vol.37, no.5, p.1261-5 (Nov. 1982). Translation of: *Zh. Prikl. Spektrosk. (USSR)*, vol.37, no.5, p.771-5 (Nov. 1982). [received: Sept. 1983]
Blood plasma lipoproteins (LP) transport lipids between cells of various tissues in organisms. According to their specific density, the LP particles are subdivided into the following main classes: very low density (VLDL), low density (LDL), and high density (HDL). The latter in turn are subdivided into two subclasses: HDL_2 and HDL_3. The LP of different classes differ in their apoprotein composition, in their content of phospholipids, cholesterol, cholesterol esters, and triglycerides; they have different sizes and surface charge densities. In movement in the blood vessels, LP undergo a complex series of interconversions, accompanied by exchange of apoproteins between particles, exchange of lipids with the membranes of the cells of the vascular wall, and introduction of LP particles into cells. According to the existing concepts, VLDL and LDL transport lipids into the vascular wall, and they are classified as atherogenic, while HDL 'carry off' cholesterol and therefore possess antiatherogenic properties. The present work was conducted to determine the peculiarities of the interaction of fluorescent probes 1-anilinonaphthalene-8-sulfonate (ANS) and 2-toluidinonaphthalene-6-sulfone (TNS) with LP of different classes, the role of proteins in this interaction, and the possibility of using these probes to study protein-lipid interactions in LP particles. An investigation was made of the intrinsic tryptophan fluorescence of apoproteins, isolated with VLDL (apo-VLDL) and from (apo-HDL) in their interaction with LP of different classes. (10 refs.)

109955 Conformation of purine mononucleotides by H{H} and P{H} nuclear Overhauser effects. H.Santos, A.V.Xavier (Centro de Quimica Estrutural, Univ. Nova de Lisboa, Lisboa, Portugal), C.F.G.C.Geraldes.
Can. J. Chem. (Canada), vol.61, no.7, p.1456-64 (July 1983).
The proton-proton and phosphorus-proton nuclear Overhauser effect (nOe) of guanosine 5′-monophosphate (5′-GMP) was measured in aqueous solution at different pH values and in the presence of excess La^{III} at acid pH. These data and nOe data from the literature for other mononucleotides were used together with vicinal proton-proton coupling constants to investigate the conformations of mononucleotides in aqueous solution, especially their rotational state about the glycosidic bond. Comparison of observed and calculated enhancements using various conformational models for the glycosidic bond gave predominantly anti conformations for 5′-AMP and 5′-GMP and a mixture of syn and anti conformations for 2′-AMP, 2′-GMP, 3′-AMP, and 3′-GMP. Protonation of 5′-GMP at N-7 of the guanine base alters the amplitude of its torsion angle within the anti range. (42 refs.)

109956 The structure of psoluthurin A, the major triterpene glycoside of the sea cucumber Psolus fabricii. F.-X.Garneau, J.-L.Simard, O.Harvey (Univ. du Quebec, Chicoutimi, Canada), J.W.ApSimon, M.Girard.
Can. J. Chem. (Canada), vol.61, no.7, p.1465-71 (July 1983).
The isolation of the major triterpene glycoside from the sea cucumber Psolus fabricii obtained from the north shore of the St. Lawrence estuary is described. Versatile extraction and purification procedures were used and physico-chemical data are presented in support of structure **1** for psoluthurin A. (32 refs.)

109957 Discovery of periodicity in structure of melanoprotein granules of eye pigment epithelium cell (small-angle X-ray investigation). Yu.M.L'vov, A.V.Krivandin, I.B.Fedorovich, M.A.Ostrovskii (A.V. Shubnikov Inst. of Crystallography, Acad. of Sci., USSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.114-16
An X-ray structural analysis of a pure suspension of granules obtained from the eye of a dark-adapted frog (Rana temporaria) is reported. The authors have obtained the first X-ray diagrams of melanoprotein granules from eye pigment epithelium cells. The X-ray diagrams contain four reflections, which indicate an ordered internal structure of the granules. The mean repetition period is about 60 Å. The repeating subunits are probably protein granules with a liquid-type packing. The relation between the detected structure of the melanoprotein granule and its photophysical properties is of considerable interest. (8 refs.)

109958 Theory of cooperative transitions in protein globules. E.I.Shakhnovich, A.V.Finkel'shtein (Inst. of Protein, Acad. of Sci., Pushchino, USSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.175-8
Short-lived interactions of side groups with one another and with the main chain are discussed. Hydrophobic and electrostatic interactions are considered. It is shown that the melting of the protein globule is not necessarily accompanied by complete unfolding of the molecule. (8 refs.)

109959 Conformation and dynamics of carcinogenic N-substituted 2-aminofluorene compounds studied by nuclear magnetic resonance spectroscopy. F.E.Evans, D.W.Miller (Div. of Chem., Nat. Center for Toxicological Res., Food & Drug Administration, Jefferson, AR, USA).
J. Am. Chem. Soc. (USA), vol.105, no.15, p.4863-8 (27 July 1983).
The conformation and dynamics associated with the aryl-nitrogen bond and the amide bond of 2-(acetylamino)fluorene (AAF) as well as the *N*-hydroxy, *N*-acetoxy, and *N*-sulfate derivatives were investigated as an initial step toward analysis of the orientation of AAF in modified nucleic acids. ^{1}H, ^{13}C, and ^{15}N nuclear magnetic resonance spectroscopic data at low temperatures were obtained for each compound. The equilibrium distribution of conformers about the amide bond in temperatures were obtained for each compound. The equilibrium distribution of conformers about the amide bond in *N*-hydroxy-AAF and *N*-acetoxy-AAF, which was unusually favorable for aryl amides, enabled a detailed structural study. A barrier to internal rotation about the amide bond of 14.4 and 13.7 kcal/mol was computed for *N*-hydroxy-AAF and *N*-acetoxy-AAF, respectively. There was rapid rotation about the aryl-nitrogen bond, with the preferred torsion angle about the aryl-nitrogen bond being interrelated to the conformation with the amide bond and the nature of the N substituent. (30 refs.)

109960 EPR evidence on the structure of the copper(II)-bacitracin A complex. E.G.Seebauer, E.P.Duliba, D.A.Scogin, R.B.Gennis, R.L.Belford (School of Chem. Sci., Univ. of Illinois, Urbana, IL, USA).
J. Am. Chem. Soc. (USA), vol.105, no.15, p.4926-9 (27 July 1983).
Bacitracin is an antibiotic that is effective only in the presence of divalent metal cations. The possible sites for the binding of divalent transition metal ions to bacitracin A are investigated by electron paramagnetic resonance. Manganese(II) shows only the characteristics of the aqueous ion. High-spin cobalt, suggesting distorted octahedral coordination, is indicated from the cobalt(II) EPR spectra. The copper(II) complex yields a rich spectrum and detailed structural information. The electronic Zeeman, hyperfine, and nuclear quadrupole coupling parameters show that copper is most probably square planar, coordinated to the glutamate γ-carboxyl, the histidine imidazole, the aspartate β-carboxyl, and the thiazoline nitrogen. (21 refs.)

109961 Determination of the absolute handedness of knots and catenanes of DNA. M.A.Krasnow (Dept. of Molecular Biology, Univ. of California, Berkeley, CA, USA), A.Stasiak, S.J.Spengler, F.Dean, T.Koller, N.R.Cozzarelli.
Nature (GB), vol.304, no.5926, p.559-60 (11 Aug. 1983).
DNA winds about itself in a right-handed or left-handed fashion at several structural levels. The double helix is generally right-handed and is given a (+) sign by convention, whereas supercoiling of the helix axis is always (−) in the cell. The winding in higher-order forms such as knots and catenanes is unknown, and this has impeded elucidation of the mechanisms of their formation and resolution by replication, recombination and topoisomerase action. The authors introduce a procedure for determining the handedness of DNA winding by inspection of electron micrographs of DNA molecules coated with Escherichia coli RecA protein. They demonstrate the validity of the method and show that DNA topoisomerase I of *E. coli* generates an equal mixture of (+) and (−) duplex DNA knots, and that one product of recombination by resolvase of transposon Tn*3* is a catenane of uniquely (+) sign. (17 refs.)

109962 Dependence of DNA helix flexibility on base composition. M.Hogan, J.LeGrange (Dept. of Biochem. Sci., Princeton Univ., Princeton, NJ, USA), B.Austin.
Nature (GB), vol.304, no.5928, p.752-4 (25 Aug. 1983).
The authors have used triplet anisotropy decay techniques to study the flexibility of synthetic DNA fragments with different base pair compositions. They have found major differences in the torsional and bending stiffness of poly(dG).poly(dC), poly(dA).poly(dT) and poly(dA-dC).poly(dT-dG). Poly(dG).poly(dC) has a torsional modulus more than 40 times larger than poly(dA-dC).poly(dT-dG), and approximately 20 times larger than poly(dA).poly(dT). These differences imply that the torsional stiffness of DNA can vary greatly with base composition. The Young's modulus (bending stiffness) measured by the authors for poly(dG).poly(dC) is at least twice that of poly(dA-dC).poly(dT-dG) or random sequence DNA, and is at least threefold greater than that of poly(dA).poly(dT). This implies that the bending stiffness of DNA is also strongly dependent on base composition. In light of this dramatic base composition dependence, the authors suggest that such stiffness variation may lead to local variations in the stability of chromatin or other protein complexes that require bending or twisting of the DNA helix. (19 refs.)

109963 Shapes of and distances between components within the large (50S) subunit of *E.* coli ribosomes. K.H.Nierhaus (Max-Planck-Inst. fur Molekulare Genetik, Berlin-Dahlem, Germany), R.Lietzke, V.Nowotny, H.Schulze, P.Wurmbach, H.B.Stuhrmann, R.P.May.
Physica B & C (Netherlands), vol.120B+C, no.1-3, p.426-35 (May 1983). (Yamada Conference VI on Neutron Scattering in Condensed Matter, Hakone, Japan, 1-4 Sept. 1982).
The large (50S) subunit of *E.* coli ribosomes consists of 32 different proteins and two RNA molecules. Ribosomes are heterogeneous towards neutrons, since RNA and proteins hve different neutron scattering densities. This obstacle for shape determinations of single ribosomal components within the ribosome could be overcome by homogenizing (matching) the neutron scattering densities of RNA and proteins. Model calculations demonstrated that the direct determination of radii of gyration should be experimentally feasible. RNA from the large ribosomal subunit was isolated from cells grown in a medium containing 76% D_2O, the total protein fraction of that from cells grown in 84% D_2O. 50S subunits reconstituted from both constituents match near 100% D_2O. Experiments with single protonated proteins within the deuterated, matched ribosome proved the feasibility of the biochemical strategy outlined above. The shape determinations of ribosomal proteins in situ revealed radii of gyration for L1, L2, L3, L4, and L23 of 26±2, 22±2, 22±2, 20±2, and 13±2 Å, respectively. (17 refs.)

109964 Small angle neutron scattering studies of the structure of nucleosome cores at low ionic strength. K.Mita (Div. of Chem., Nat. Inst. of Radiological Sci., Chiba, Japan), M.Zama, S.Ichimura, N.Niimura, K.Kaji, M.Hirai, Y.Ishikawa.
Physica B & C (Netherlands), vol.120B+C, no.1-3, p.436-9 (May 1983). (Yamada Conference VI on Neutron Scattering in Condensed Matter, Hakone, Japan, 1-4 Sept. 1982).
The structure of the nucleosome core particle at low ionic strength (10-0.04 mM Na^+) has been studied by small angle neutron scattering in various H_2O/D_2O mixtures. At 0.04 mM Na^+, the radius of gyration obtained at 39% of D_2O where scattering from the DNA dominates was 32 Å, and at 65% D_2O where scattering from the histones dominates, 40 Å. An abrupt increase in the radius of gyration from 35 to 40 Å was observed at about 1 mM ionic strength at 65% D_2O, with decreasing the ionic strength from 10 mM. No loss of the histone secondary structure was detected by circular dichroism over the range of the ionic strength examined. These results suggest that at low ionic strength ($\lesssim$1 mM) the histones are located outside of the nucleosome core particle accompanied by an alteration of the tertiary and/or quaternary structure of the histone octamer, with the DNA in a folded conformation. (26 refs.)

109965 Folding-unfolding of α-lactalbumin. Y.Izumi, Y.Miyake, K.Kuwajima, S.Sugai (Faculty of Sci., Hokkaido Univ., Sapporo, Japan), K.Inoue, M.Iizumi, S.Katano.
Physica B & C (Netherlands), vol.120B+C, no.1-3, p.444-8 (May 1983). (Yamada Conference VI on Neutron Scattering in Condensed Matter, Hakone, Japan, 1-4 Sept. 1982).
X-ray and neutron small-angle scattering and quasi-elastic neutron scattering measurements are reported for bovine α-lactalbumin. The conformation at the native (N), the stable intermediate (A), and the fully unfolded (D) states and transition processes among them are examined on the basis of a phase diagram. The conformation of the A state at acid pH is typical of a globular protein. The conformation at the A state has a more or less expanded form than that at the N state. Preliminary analysis and discussion based on the Gaussian approximation are well explained by the model of folding previously presented. (8 refs.)

109966 Direct visualization of unstained nucleic acids on a metal substrate. J.A.Panitz (Sandia Nat. Lab., Albuquerque, NM, USA).
Ultramicroscopy (Netherlands), vol.11, no.2-3, p.161-6 (1983). (Surface Imaging and Analysis with High Spatial Resolution, Wickenburg Inn, AZ, USA, 12-15 Jan. 1983).
Unstained DNA has been directly imaged for the first time on a metallic substrate. Reproducible, three-dimensional images of molecular morphology following aqueous deposition onto tungsten have been obtained. The images confirm the importance of reducing surface tension forces during drying. Preadsorption of poly-1-lysine seems to improve image quality although optimum conditions are quite different than those reported in the TEM literature for insulating substrates. The results suggest that poly-1-lysine should be preadsorbed as a neutral molecule at high pH. Following adsorption, the pH should be reduced in order to establish a net positive surface charge density. The presence of positive charges on a tungsten surface helps to preserve DNA morphology following adsorption from aqueous solution. (16 refs.)

109967 Quasi-elastic light scattering studies on T7 DNA in the presence of a sinusoidal electric field. K.S.Schmitz (Dept. of Chem., Univ. of Missouri, Kansas City, MO, USA).
Chem. Phys. (Netherlands), vol.79, no.2, p.297-305 (1 Sept. 1983).
Quasi-elastic light scattering studies on T7 DNA were performed with a sinusoidal electric field applied across the sample. The resulting spectral densities exhibited several peaks whose number and magnitude depended upon the parameter z ($=\mu EK\cos(\theta/2)/2\pi\nu'$, where μ is the apparent electrophoretic mobility, E is the magnitude of the applied electric field of frequency ν', K is the scattering vector, and θ is the scattering angle). These data suggest two asymptotic values for the electrophoretic mobility, the high-frequency limit being associated with the center-of-mass motion of the T7 DNA and the low-frequency limit being identified with small-ion polyion coupled motions. (40 refs.)

109968 NMR of water in biological systems. I. Theoretical considerations. M.Villa, L.Borghi, A.De Ambrosis, S.Aldrovandi (Istituto di Fisica, Pavia, Italy).
Nuovo Cimento D (Italy), vol.2D, ser.1, no.4, p.1019-32 (July-Aug. 1983).
A simple relationship has been thought to exist between the dynamics of water in heterogeneous (liquid-solid) systems and the NMR response. This relationship is usually expressed by the Bloembergen-Purcel-Pound (BPP) equations for relaxation and the phase model. However, a requirement for the use of the BPP theory is that motions take place in an isotropic, infinite and three-dimensional space. It is shown that the mere presence of solid surfaces causes the appearance of solid like features in the NMR response of the liquid even if its dynamics is directly affected by the surfaces. Some of these 'topological' or 'indirect' surface effects are of the same kind as the low-dimensionality effects. Their order of magnitude is estimated for simple geometries and by treating the liquid motion in a hydrodynamic approximation. Comparison with the experiment is carried on in a companion paper. (21 refs.)

109969 NMR of water in biological systems. II. Comparison with the experiments. L.Borghi, A.De Ambrosis, S.Aldrovandi, M.Villa (Istituto di Fisica, Pavia, Italy).
Nuovo Cimento D (Italy), vol.2D, ser.1, no.4, p.1033-49 (July-Aug. 1983).
For pt.I see ibid., vol.2, p.1019 (1983). An extensive investigation of water NMR response in the muscular tissue (frog gastrocnemius) is presented. The authors' data are compared with the predictions of the 'cage models' (discussed in a companion paper), which envisions a single water phase subjected to topological constraints. Several features of the NMR response are easily accounted for by the cage models. Instead, other features give clear evidence for the existence of different phases of water. They performed also an analysis of NMR data for biological and model systems studied in the literature. They suggest that, in most cases, it is more appropriate to interpret NMR data in terms of a single water phase with an average mobility somewhat reduced with respect to that of free water, rather than in terms of several ill-characterized phases. (24 refs.)

109970 Solvent-peak-suppressed NMR: correction of baseline distortions and use of strong-pulse excitation. P.Plateau, C.Dumas, M.Gueron (Groupe de Biophys., Ecole Polytech., Palaiseau, France).
J. Magn. Resonance (USA), vol.54, no.1, p.46-53 (Aug. 1983).
Pulse excitation sequences which involve time delays lead to spectra suffering from so-called frequency-dependent phase shifts. The phenomenon is analyzed in a model case, and the above description is shown to be somewhat improper. Rather, the spectrum should be described as a sum of Lorentzian lines, each of which has its own, frequency-independent, phase shift. The analysis leads to procedures for correcting the baseline distortions of solvent-suppressed NMR based on the Redfield 2-1-4 sequence, or on analogous strong-pulse sequences which are described. Goals and methods of solvent-signal suppression are discussed in this context. (10 refs.)

87.16 BIOTHERMICS

109971 Non-linear effects in the electromagnetic heating of living tissues. F.Bardati, G.Gerosa (Dipartimento di Elettronica, Univ. di Roma, Roma, Italy).
Alta Freq. (Italy), vol.52, no.3, p.170-2 (May-June 1983). (4th Italian National Meeting on Applied Electromagnetics, Florence, Italy, 4-6 Oct. 1982).
With reference to local microwave induced hyperthermia for cancer therapy, the problem of the electromagnetic heating of living tissues has been considered. In order to take into account local thermoregulating effects, a nonlinear model of the thermal behaviour of the biological tissue has been assumed. The temperature distribution induced by exposure to electromagnetic fields has been obtained by using the iterative Newton method. With reference to a particular case, a numerical analysis has been carried out for various values of the nonlinear coefficients of the model, in order to evaluate the matching between the assumed mathematical model and the true biological phenomena. (6 refs.)

109972 Pseudo-critical heat capacity of single lipid bilayers. I.Hatta, K.Suzuki (Dept. of Appl. Phys., Nagoya Univ., Nagoya, Japan), S.Imaizumi.
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2790-7 (Aug. 1983).
By an AC calorimeter the heat capacity of aqueous suspensions of dipalmitoylphosphatidylcholine has been measured near the pretransition and main transition. The anomaly at the main transition exhibits a sharp divergence, i.e. the fluctuation at the transition is certainly dominant, although they undergo first-order transition. The pseudo-critical behavior is analyzed in terms of critical-exponent expressions: α and α' are 0.40 ± 0.05 and 0.4 ± 0.1 respectively. Using Pipard's relations, the dependence of the transition temperature on pressure is discussed, which is almost consistent with that of the direct experiments. The anomaly at the pretransition observed by a differential scanning calorimeter is extremely reduced in AC calorimetry. This is due to the frequency dispersion of the heat capacity, since the relaxation at this transition is very long. (18 refs.)

109973 Coaxial nonmetallic thermocouple with electronic ice point for dosimetric use in electromagnetic environments. R.G.Olsen, W.C.Hammer, J.C.Taylor (Aerospace Medical Res. Lab., Pensacola, FL, USA).
J. Microwave Power (Canada), vol.17, no.2, p.137-43 (June 1982).
A refined version of the nonmetallic thermocouple (NMT) is presented along with results of microwave dosimetric testing of the device in a practical laboratory environment. A smaller device was achieved by using coaxial conductors of a dissimilar nature, and a slightly modified, commercially available electronic ice point provided temperature compensation of the secondary junctions adequate for normal laboratory use. Results of practical dosimetric comparisons in tissue-equivalent material between the coaxial NMT and a widely used, more sophisticated temperature probe showed mean specific absorption rate to vary between 13.6% and 31%, but no statistically significant difference was observed in instances where the probes were compared at identical locations during irradiation. (11 refs.)

109974 Heat-stress proteins and thermal resistance in rat mammary tumor cells. S.P.Tomasovic, P.A.Steck, D.Heitzman (Dept. of Tumor Biology, Univ. of Texas, Houston, TX, USA).
Radiat. Res. (USA), vol.95, no.2, p.399-413 (Aug. 1983).
Exposure of clone MTC rat 13672NF mammary adenocarcinoma cells to continuous heating at 42°C or to heating for 20 min at 45°C followed by incubation at 37°C induced or enhanced synthesis of several heat-stress proteins (HSP) detectable by $[^3$H]leucine pulse labeling, gel electrophoresis, and fluorography. HSP synthesis occurred during development and expression of thermal resistance. For example, continuous heating of MTC cells at 42°C after a rapid temperature transient (about 4 min) produced thermal resistance within 4 to 5 hr of initiation of heating. HSP synthesis was observed within 2 hr of the cells reaching 42°C and continued throughout 8 hr of heating; four major HSP appeared at nominal molecular weights of 112, 90, 70, and 22 kDa. A slow temperature transient from 37° to 42°C over a 3-hr period increased thermal resistance by a factor of about 2 relative to a rapid transient or 'shock' to 42°C. However, HSP synthesis was not significant during the slow heat transient and was either reduced (at 70 and 22 kDa) or not increased (at 112 and 90 kDa) compared with the rates of HSP synthesis at the same time intervals after the rapid transient to 42°C. In these mammary tumor cells, no differences in the number of HSP were detected during heating at 42°C or after 45°C heating. (58 refs.)

87.20 MEMBRANE BIOPHYSICS

109975 Stochastic problems in information transfer across the plasma membrane. C.DeLisi (Lab. of Math. Biology, National Cancer Inst., Bethesda, MD, USA).
Bull. Math. Biol. (GB), vol.45, no.4, p.467-82 (1983).
The surfaces of many cells are viscous fluids; consequently, most membrane proteins are able to diffuse laterally in a more or less random fashion, with diffusion coefficients typically of order 10^{-10} cm^2/sec. Evidence from a variety of systems indicates that such receptor clustering plays a role in the sequence of events leading to cellular activity. The paper describes a number of mathematical problems that arise in the analysis of experiments in which clustering occurs. The author begins by reviewing methods for finding the time evolution of the cluster size distribution function in terms of reaction rate constants. The methods solve an essentially infinite system of coupled nonlinear differential equations. Next, the rate constants are analyzed, the Brownian motion problems that arise in attempting to understand ligand recognition are described and relevant experimental systems are discussed. Finally the notion of ligand as a signal amplifier is introduced—an idea that emerges naturally from the requirement that receptors be clustered for a finite amount of time before a signal can be transmitted. (27 refs.)

109976 Application of hybrid image processing for the determination of the optical properties of cellular membranes. M.Chevalier (Dept. de Fisica Medica, Facultad de Medicina, Univ. Complutense, Madrid, Spain), M.L.Calvo.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.59-66 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A biological cell is considered as a bidimensional phase object. As the different parts of the cell have not the same optical density, it has a density profile corresponding to an inhomogeneous object. That means that, in spatial frequencies, it is possible to identify the different contributions to the morphology of the cell. The methods used are complementaries: (1) numerical simulation; (2) digitalisation of the Fourier spectrum; (3) optical-non-destructive methods: obtention of the optical Fourier spectrum. The possibilities of obtaining information using spatial frequency filtering techniques are discussed. (8 refs.)

109977 Spin exchange in nitroxide-charged membrane models: an ESR method for detecting photodynamic effects. C.Emiliani, S.Cannistraro (Dipartimento di Fisica, Univ. di Perugia, Perugia, Italy).
Nuovo Cimento D (Italy), vol.2D, ser.1, no.4, p.1203-12 (July-Aug. 1983).
An electron spin resonance (ESR) method for detecting the photodynamic effects induced in membrane models is described. The method is based on the study of the spin exchange line broadening occurring in nitroxide-charged lipsomes before and after visible irradiation in the presence of various photosensitizing molecules. (17 refs.)

109978 Possibility of ferroelectricity in biomembranes. L.A.Beresnev, L.M.Blinov, E.I.Kovshev (Sci.-Res. Inst. of Organic Intermediates & Dyes, Moscow, USSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.111-14
It is shown that, first biological membranes of animal origin may provide all the essential symmetric conditions for ferroelectricity and, secondly that the spontaneous polarization, due to the presence of cholesterol, may be sufficiently high. The close similarity between biomembranes and ferroelectric liquid crystals is considered. (11 refs.)

109979 The ATP receptor in the membrane of sensory neurons. O.A.Kryshtal', S.M.Marchenko, V.I.Pidoplichko (A.A. Bogomolets Inst. of Physiology, Acad. of Sci., Kiev, Ukrainian SSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.172-5
Reports experiments conducted on neurons isolated from various sensory ganglia (ganglia nodosum, vestibulare, semilunare, spinale) of rats 4 to 25 days old. The results show that the membranes of sensory neurons have ionic channels that are activated by ATP. (4 refs.)

109980 Computer simulation of the main gel-fluid phase transition of lipid bilayers. O.G.Mouritsen (Dept. of Phys. Chem., Univ. of Aarhus, Aarhus, Denmark), A.Boothroyd, R.Harris, N.Jan, T.Lookman, L.MacDonald, D.A.Pink, M.J.Zuckermann.
J. Chem. Phys. (USA), vol.79, no.4, p.2027-41 (15 Aug. 1983).
Monte Carlo techniques have been applied to a study of two related quasi-two-dimensional microscopic interaction models which describe the phase behavior of phospholipid bilayers. The two models are Ising-like lattice models in which (a) the acyl chains of the phospholipids interact via anisotropic van der Waals forces and (b) the rotational isomerism of the chains is accounted for by two and ten selected conformational states, and (b) the rotational isomerism of the chains is accounted for by two and ten selected conformational states, respectively. Monte Carlo experiments are performed on both models so as to determine whether the static thermodynamic properties of lipid bilayers are most accurately represented by a simple two state gel-fluid concept or whether a more complicated melting process involving intermediate states takes place. The temperature dependence of several static thermodynamic properties has been calculated for both models. This includes the chain cross-sectional area, the internal and free energies, the coherence length, the lateral compressibility, and the specific heat. The comparison between the Monte Carlo results for the two models demonstrates that, whereas the two-state model has a first-order transition with jumplike behavior in the transition region the ten-state model exhibits a first-order transition associated with a closed hysteresis loop. Next, the Monte Carlo results for cross-sectional areas per lipid chain, coherence lengths and lateral compressibilities are discussed in the context of experimental results for dipalmitoyl phosphatidylcholine (DPPC). A Monte Carlo analysis of bilayers composed of both DPPC and cholesterol shows that a two-state model does not adequately describe the thermodynamic behavior of lipid-cholesterol mixtures implying that intermediate states have to be introduced to account for the experimental data. (59 refs.)

109981 On defects in different phases of two-dimensional lipid bilayers. D.Ruppel, E.Sackmann (Phys. Dept., Tech. Univ. Munchen, Munchen, Germany).
J. Phys. (France), vol.44, no.9, p.1025-34 (Sept. 1983).
The phospholipid bilayer is the basic structure of biological membranes as well as a suitable model of a two-dimensional system. Defects within these bilayers are studied electron microscopically by application of the freeze fracture method. Topological and non-topological defects can be distinguished. The first type is analysed in terms of the homotopy theory. Two defect systems, an Abelian and a non-Abelian, are found which are a consequence of a symmetry breaking. The effect of small amounts of impurities on the defect structure is studied. An outline of the possible biological relevance of defects is given in the last part. (23 refs.)

109982 Some aspects of the structure change of lipid bilayers associated with the thermotropic phase transition. Miscibility of different lipids in liposome bilayers. Y.Toyoshima, T.Takeda, K.Akabori, S.Komura (Faculty of Integrated Arts & Sci., Hiroshima Univ., Hiroshima, Japan).
Physica B & C (Netherlands), vol.120B+C, no.1-3, p.440-3 (May 1983). (Yamada Conference VI on Neutron Scattering in Condensed Matter, Hakone, Japan, 1-4 Sept. 1982).
Dipalmitoylphosphatidylcholine with completely deuterized acyl chains (DDPPC) was synthesized to examine the temperature dependence of miscibility of two lipids in liposomes, which differ only by two methylene units in the lengths of their acyl chains by means of neutron small angle scattering. The initiation and completion temperatures, T_h and T_l ($T_h > T_l$), of the phase change with regard to the chain ordering of the lipids were determined by the fluorescence method for the equimolar mixture of DDPPC and non-deuterized dimyristoylphosphatidylcholine (DMPC) and that of DDPPC and non-deuterized distearoylphosphatidylcholine (DSPC). Complete mixing of two lipids was observed by neutron small angle scattering only at a temperature above T_h for DDPPC/DMPC, but was not observed for DDPPC/DSPC over the temperature range examined. 87.25 CELLULAR BIOPHYSICS

109983 Stochastic models for cell kinetics. P.Jagers (Chalmers Univ. of Technol., Gothenburg, Sweden).
Bull. Math. Biol. (GB), vol.45, no.4, p.507-19 (1983).
A survey is given of branching process type methods in cell kinetics. Some results are given that allow circadian rhythm and do not require complete independence between cells. Some more classical results on balanced exponential growth are given and some comments are made on flow microfluorometry. (10 refs.)

109984 Physical properties of pathological human erythrocytes. I. A spin label study on the internal microviscosity of homozygous β-thalassemic erythrocytes. L.Sportelli (Dipartimento di Fisica, Univ. della Calabria, Calabria, Italy), A.Rosi, P.L.Indovina, C.Brancati, A.Tagarelli.
Nuovo Cimento D (Italy), vol.2D, ser.1, no.4, p.993-1004 (July-Aug. 1983).
A contribution to the study of physical properties of pathological human erythrocytes has been obtained by applying the electron spin resonance spectroscopy with spin labels. The rotational correlation time, τ_c, of the spin label tempamine has been used for a comparative study of internal microviscosity in normal and in homozygous β-thalassemic erythrocytes. Results claim for a decreased microviscosity in pathological erythrocytes as compared with normal ones. These findings suggest the hypothesis of a different water structuring process in the physiological and pathological situation inside red blood cells. (17 refs.)

109985 Physical properties of pathological human erythrocytes. II. A comparative electron spin resonance study of erythrocyte membrane in homozygous β-thalassemia. L.Sportelli (Dipartimento di Fisica, Univ. della Calabria, Calabria, Italy), A.Rosi, P.L.Indovina, C.Brancati, A.Tagarelli.
Nuovo Cimento D (Italy), vol.2D, ser.1, no.4, p.1005-13 (July-Aug. 1983).
For pt.I see ibid., vol.2, p.993 (1983). A contribution to the study of the physical properties of the human-erythrocyte membrane has been obtained by applying electron spin resonance spectroscopy with three spin labels at different penetration levels in the membrane. The order parameter S as a measure of the membrane fluidity and the hyperfine coupling constant a_N' as a measure of the membrane polarity have been determined. A comparative study of S and a_N' between normal and homozygous β-thalassemic erythrocytes has been performed. Results showed as increased polarity and a decreased fluidity in the pathological erythrocyte membrane as compared to the normal one. A model for understanding these differences has been proposed. (22 refs.)

109986 Excitation energy transfer from light-harvesting antenna to reaction center in Rhodospirillum rubrum chromatophores from data of selective picosecond spectroscopy. A.Yu.Borisov, R.A.Gadonas, R.V.Danelyus, V.S.Kozlovskii, A.S.Piskarskas, A.P.Razzhivin, S.G.Kharchenko (M.V. Lomonosov Moscow State Univ., Moscow, USSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.129-32
Presents the results of direct measurements of the kinetics of disappearance of excitations from the light harvesting antenna and subsequent oxidation of the RC in native chromatophores from the purple bacterium Rhodospirillum rubrum on the first differential picosecond absorption spectrometer, which was built at Vilnius State University. It is concluded that: 1. The B905 complexes are located in the immediate vicinity of the RC. The equality of the decay time of excitations in B905 and the rise time of RC photooxidation shows that RC traps capture excitons from B905. In other words, the B905 form acts as an effective coupling link between the main antenna pigment and the RC; 2. The energy gap between the B880 and B905 forms is 39 meV, which corresponds to upward and downward energy transfer rates in the ratio 1:5. However, taking into account that in Rh. rubrum there are 3-5 B905 molecules to approximately 50 B880 molecules, one can conclude that the quasi-steady ratio of excitations in the B880 and B905 forms will be 3:1. (15 refs.)

109987 Surface potential of thylakoid membrane, photoinduced absorption of protons, and photophosphorylation in chloroplasts. A.N.Tikhonov, A.A.Timoshin, E.K.Ruuge, L.A.Blyumenfel'd (M.V. Lomonosov Moscow State Univ., Moscow, USSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.136-8
It is known that illumination of coupled chloroplasts is accompanied by a change in potential on the outer surface of the thylakoid membrane. The results of investigations on pea seedlings, given in this paper, indicate the absence of a simple correlation between photoinduced changes in surface potential and the phosphorylation rate in chloroplasts. (11 refs.)

109988 Numerical averaging of electron micrographs of the 50S subunits of ribosomes. N.A.Kiselev, E.V.Orlova, V.Ya.Stel'mashchuk, V.D.Vasil'ev, O.M.Selivanova, V.P.Kosykh, A.I.Pustovskikh, V.S.Kirichuk (A.V. Shubnikov Inst. of Crystallography, Acad. of Sci., Moscow, USSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.182-5
The main result of this work is the confirmation by numerical methods of the results of visual examination and optical averaging of the large ribosomal subunits. The observed 'fine structure' is one of the projections of the three-dimensional structure of the ribosomal subunits revealed by negative contrasting with uranyl acetate. When data for other projections of this subunit have been collected and information obtained about the position of the protein molecules by immune electron microscopy and other techniques has been taken into account. It will be possible to establish the quaternary structure of ribosomes. (9 refs.)

87.25D Biological transport; cellular and subcellular transmembrane physics

109989 Diffusional resistances to oxygen transfer in whole blood. J.C.Merchuk, Z.Tzur (Dept. of Chem. Engng., Ben Gurion Univ. of the Negev, Beer-Sheva, Israel), E.N.Lightfoot.
Chem. Eng. Sci. (GB), vol.38, no.8, p.1315-21 (1983).
The authors investigate the resistance to oxygen transfer from the red blood cell by a modified rapid flow technique. It is found that the transfer of oxygen in the boundary layer surrounding the red blood cell can account for all of the transport resistance found in these experiments. (23 refs.)

109990 Basic principles of structural organization of ionic channels responsible for depolarization of excitable cell membranes. P.G.Kostyuk (A.A. Bogomolets Inst. of Physiology, Acad. of Sci., Kiev, Ukrainian SSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.143-5
The very complex problem of separating mono- and divalent cations and producing the corresponding specific ionic currents in the excitable neuronal membrane may be solved by recourse to at least three different physicochemical mechanisms, the carrier of each of which is probably a special structural part of the corresponding ionic channels. These structural parts can function in different combinations in different types of ionic channels and are possibly synthesized by the cell as separate subunits, which are then combined when they are built into a single molecular structure—the ionic channel—in the membrane. (12 refs.)

109991 Oscillations of intracellular Ca^{2+} in mammalian cardiac muscle. C.H.Orchard, D.A.Eisner, D.G.Allen (Dept. of Physiology, Univ. Coll. London, London, England).
Nature (GB), vol.304, no.5928, p.735-8 (25 Aug. 1983).
In certain conditions of Ca^{2+}-loading the normal cardiac contraction is followed by an aftercontraction. The rise of intracellular calcium concentration ($[Ca^{2+}]$i) which is thought to underlie the aftercontraction also produces a transient inward current. This current, which probably results from a Ca^{2+}-activated nonspecific cation conductance, has been implicated in the genesis of various cardiac arrhythmias. However, despite the potential importance of such fluctuations of $[Ca^{2+}]$i their existence has, so far, only been inferred from tension measurements. Here the authors present direct measurements of such oscillations of $[Ca^{2+}]$i based on experiments on ferret papillary muscles. (20 refs.)

109992 Ligand-induced rapid redistribution of lysosomes is temporally distinct from endosome translocation. B.Herman, D.F.Albertini (Dept. of Anatomy, Harvard Medical School, Boston, MA, USA).
Nature (GB), vol.304, no.5928, p.738-40 (25 Aug. 1983).
Although the translocation of endosomes to the Golgi region in the cell centre seems to be a general phenomenon presumably coupled to ligand degradation by lysosomes, and endosomes and lysosomes undergo saltatory movements within the cytoplasm, the spatial control of interaction between the two structures is not understood. To address this problem the authors have begun to examine the spatial and temporal intracellular distribution of endosomes and lysosomes. Utilizing a new fluorescent microscopic approach, they have now been able simultaneously to visualize endosome and lysosome populations in living cells. The results suggest that a specific relocation of lysosomes is rapidly induced upon binding of different types of ligands to the cell surface; this migration of lysosomes to the Golgi region of the cell precedes the translocation of endosomes into the same area. (28 refs.)

109993 ATP-regulated K^+ channels in cardiac muscle. A.Noma (Nat. Inst. for Physiological Sci., Okazaki, Japan).
Nature (GB), vol.305, no.5930, p.147-8 (8 Sept. 1983).
An outward current of unknown nature increases significantly when cardiac cells are treated with cyanide or subjected to hypoxia, and decreases on intracellular injection of ATP. The author reports that application of the patch-clamp technique to CN-treated mammalian heart cells reveals specific K^+ channels which are depressed by intracellular ATP (ATP_i) at levels greater than 1 mM. For these channels, conductance in the outward direction is much larger than the inward rectifier K^+ channel which is insensitive to ATP. AMP had no effect on the ATP-sensitive K^+ channel, and ADP was less effective than ATP. Thus, the ATP-sensitive K^+ channel seems to be important for regulation of cellular energy metabolism in the control of membrane excitability. (18 refs.)

109994 Quantification of Ca^{2+}-activated K^+ channels under hormonal control in pig pancreas acinar cells. Y.Maruyama, O.H.Peterson, P.Flanagan, G.T.Pearson (Physiological Lab., Univ. of Liverpool, Liverpool, England).
Nature (GB), vol.305, no.5931, p.228-32 (15 Sept. 1983).
Using patch-clamp methods to record single-channel currents from excised fragments of baso-lateral acinar cell membranes in combination with current recordings from isolated single acinar cells and two- and three-cell clusters, the authors have for the first time characterized K^+ channels quantitatively. In pig pancreatic acini there are 25-60 K^+ channels per cell with a maximal single channel conductance of about 200 pS. The authors have quantified the relationship between internal ionized Ca^{2+} concentration ($[Ca^{2+}]_i$) membrane potential and open-state probability (p) of the K^+ channel. By comparing curves obtained from excised patches relating membrane potential to p, at different levels of $[Ca^{2+}]_i$, with similar curves obtained from intact cells, $[Ca^{2+}]_i$ in resting acinar cells was found to be between 10^{-8} and 10^{-7} M. In microelectrode experiments acetylcholine, gastrin-cholecystokinin as well as bombesin peptides evoked Ca^{2+}-dependent opening of the K^+ conductance pathway, resulting in membrane hyperpolarization. 87.30 BIOPHYSICS OF NEUROPHYSIOLOGICAL PROCESSES

(exc. perception processes and speech)

109995 Motor unit activity and muscle strength development. G.A.Wood, R.J.Lockwood, A.G.Creswell, J.Henstridge (Dept. of Human Movement & Recreation Studies & Biometrics, Univ. of Western Australia, Nedlands, Australia).
Australas. Phys. & Eng. Sci. Med. (Australia), vol.6, no.2, p.71-5 (April-June 1983). [received: Aug. 1983]
Neural factors have been found to play a significant role in human muscular strength development, as evidenced by quantitative changes in electromyographic activity recorded during maximum voluntary contractions. These changes are suggestive of an altered pattern of motor unit firing in that the coincidence of several motor units firing at one and the same time is greater than could be accounted for by chance alone. Further, the authors' experiments have shown that this altered pattern of firing is not commensurate with the electromyographic pattern associated with muscular fatigue. Whereas altered spinal reflex activity accounts for much of the fatigue pattern, long loop reflexes appear to be an important factor in strength adaptation. These findings are based on a series of studies in which young adult subjects were trained on an isokinetic dynamometer for 4-6 weeks. Electromyographic signals were subjected to power spectral analysis and examined for significant shifts in the spectrum. (16 refs.)

109996 Stochastic processes in neurophysiology: transformation from point to continuous processes. A.V.Holden (Dept. of Physiology, Univ. of Leeds, Leeds, England).
Bull. Math. Biol. (GB), vol.45, no.4, p.443-65 (1983).
The spike train activity of neurones is considered as a point process, and methods of analysing and interpreting recorded spike trains are considered. The generation of a continuous process (membrane noise) from interacting point processes is described. (63 refs.)

109997 A note on the sample serial autocorrelation function of stationary spike trains. D.Schild (Zentrum Physiologie und Pathophysiologie, Univ. Gottingen, Gottingen, Germany).
Biol. Cybern. (Germany), vol.47, no.2, p.147-8 (1983).
The computation of the sample serial autocorrelation of a spike train is reasonable under the condition that the underlying process is stationary and linear. If these conditions are not fulfilled, the sample serial autocorrelation is random and any interpretation of it is erroneous. On the other hand, if the conditions are proved to hold, there is little need for the computation of the sample serial correlation, since in nearly all practical cases the stationarity is approximated by stationarity in the wide sense, which means that the deterministic autocorrelation of the process is already known. (7 refs.)

109998 Equalization of the coherence of rhythms in EEG and its functional significance. N.D.Nikolov (Central Lab. for Brain Res., Bulgaria Acad. of Sci., Sofia, Bulgaria).
C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.5, p.659-62 (1983).
The coherent function (CF) shows the interconnection between two signals by investigating the frequency components contained in them. It offers a number of advantages in studying the interrelations between rhythms in the bioelectric activity of two formations (the so-called spatial synchronization) over their power spectra or the cross-correlation function between them. In processing experimental data for studying spatial synchronization by means of CF the author obtained certain results which may be regarded as the correlate of improved functional state of the central nervous system (CNS). What he had in mind is a process of equalization of the coherences between the individual pairs of brain structures (i.e. changes in intercoherent relations). The experiments were carried out with male adult rats with implanted electrodes in the visual (V) cortex, in the sensomotory (M) cortex, in the hippocampus (H) and in the mesencephalic locomotory zone (F). Two groups of 4 animals each were investigated: at one and the same state (wakeful, calm) a control group and a group which had gone through motor loading over a period of 25 months. (8 refs.)

109999 Anaesthesia. Anaesthetic effects of inert gases in relation to the biomedium structure. G.F.Cerofolini (Istituto di Chimica Fisica, Politecnico di Milano, Milano, Italy).
Nuovo Cimento D (Italy), vol.2D, ser.1, no.4, p.1156-62 (July-Aug. 1983).
A new theory of anaesthesia is proposed. This theory is based on the hypothesis that the narcotic gas displaces water-structure-disordering ions from the cells, thus forbidding nerve excitation. (8 refs.)

110000 Effect of calcium ions on inactivation of inward current of dialyzed Helix pomatia neurons. E.V.Narushyavichus, M.Sh.Rapoport (Kaunas Medical Inst., Kaunas, USSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.117-19
The experiments reported were conducted by intracellular dialysis of isolated Helix pomatia neurons and voltage clamping on their somatic membrane. The authors investigated the inward ion current conveyed through the membrane calcium channel. The inward current inactivation time constant (τ_n) was determined directly from the experimental traces by the straightening method. The free-calcium concentration in the dialyzing solution was altered by the addition of Ca-EGTA buffer. It was found that a change in free-calcium concentration inside the cell ($[Ca^{2+}]_i$), also in the membrane potential, caused a change in the time characteristics of the Ca and Sr inward currents. With increase in positive potential inside the cell the values of τ_n, and also the increase in $[Ca^{2+}]_i$, were reduced. A change in extracellular Ca^{2+} or Sr^{2+} concentration had no effect on τ_n of the inward current. (9 refs.)

110001 Passage of manganese and zinc ions through the calcium channel of mollusc neurons. V.N.Ponomarev, D.Zablotskaite, E.V.Narushyavichyus (Kaunas Medical Inst., Kaunas, USSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.119-21
The aim of the work reported was to investigate the possible passage of divalent Co, Ni, Cd, Mg, Mn, and Zn ions, which are known to be calcium-current blockers through the calcium channel of isolated neurons of the edible snail Helix pomatia and the pond snail Limnaea stagnalis. The experiments were conducted in voltage-clamp conditions in conjunction with intracellular dialysis of neurons on a pore. The experiments showed that when the initial external solution was replaced by a solution with cobalt (2 mM), nickel (2 mM), or cadmium (1 mM) ions the inward current was reduced to zero in 5-10 sec. On change back to the initial solution the inward current usually returned to its previous value. The addition of cadmium ions (1 mM) to an external solution containing 5 mM $MnCl_2$ or 10 mM $ZnCl_2$ completely

blocked the inward current. The authors conclude that the calcium channel in isolated neurons of the edible snail is permeable to manganese and zinc ions, as well as to calcium, strontium, and barium ions. (9 refs.)

110002 Cyclic variation of integrated delta components during nocturnal sleep in mentally retarded children. M.Shibagaki, S.Kiyono (Dept. of Physiology, Inst. for Dev. Res., Aichi Prefectural Colony, Kasugai, Aichi, Japan).
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.190-3 (Aug. 1983).
The cyclic variation of the integrated delta component in 80 mentally retarded children (from 2 months to 12 years of age) was studied throughout nocturnal sleep, and the following results were obtained. In 62 out of 80 subjects the high integrated delta rhythm power was noted in sleep EEG. In 11 out of the 80, low integrated delta rhythm power was found. In the remaining 7 subjects, no integrated delta rhythm power was found throughout nocturnal sleep. A significant increase in abnormal clinical EEG was found in subjects without delta rhythm power as compared to those with high delta rhythm power. A significant decrease in DQ was found in the subjects without delta rhythm power as compared to those with high and low delta rhythm powers. (9 refs.)

110003 Propagation of seizure activity in kindled dogs. N.J.I.Mars (Section Medical Informatics, Univ. of Leiden, Leiden, Netherlands), F.Lopes Da Silva.
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.194-209 (Aug. 1983).
The problem of determining the location of epileptogenic foci has been studied by means of a new analysis technique, the AAMI method. The spread of seizure activity in several seizures of 3 dogs, made epileptic by the kindling process, has been analyzed, using depth recording. The focus was located in the prepyriform cortex (PPC). The spread of activity from there to the amygdala was observed. It was found that seizures can be divided into 3 phases. In the first phase (lasting up to 5 sec after the kindling stimulus) no relationship between PPC and amygdala was found. In the second phase (5-13 sec) a strong relationship between these areas was found, with consistent delay times which decreased during this interval from 19.1 to 23.6 msec at the beginning to 11.3 to 16.0 msec at the end of the interval. In the third phase of the seizures (after about 13 sec post kindling) activity in the reported areas was found to be independent again. A possible neurophysiological interpretation of these findings is given. (23 refs.)

110004 Relationship between the surface e.m.g. and muscular force. G.C.Ray (Dept. of Electrical Engng., Panjab Engng. Coll., Chandigarh, India), S.K.Guha.
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.579-86 (Sept. 1983).
Most of the theoretical studies relating the surface electromyogram (s.e.m.g.) to muscular force suggest that the amplitude of the e.m.g. should increase proportionately with the square root of the tension. However, direct experiments have shown a linear relationship. The reasons for this difference are the oversimplified assumptions adopted in the various models. These models assume that all the motor units are the same size. Also, variations in action potential magnitudes and firing frequency have not been taken into account. Recent physiological experiments have contradicted these assumptions and the various parameters have now been mathematically correlated. If these mathematical correlations are incorporated in a model, the linearity between the s.e.m.g. and the muscular force is greatly improved. (14 refs.)

110005 Conductance and dye permeability of a rectifying electrical synapse. J.F.Margiotta, B.Walcott (Dept. of Anatomical Sci., State Univ. of New York, Stony Brook, NY, USA).
Nature (GB), vol.305, no.5929, p.52-5 (1 Sept. 1983).
Giant motor synapse (GMS) conductance and dye permeability were examined at thoracic and abdominal levels of the crayfish nerve cord. At both levels, values of GMS chord conductance fit a simple Boltzmann model in which the conductance of individual synaptic channels is assumed to be voltage dependent. Moreover, thoracic synapses display higher limiting conductances than do those at an abdominal level, apparently as a result of their larger size. The authors also find that synapses at both locations are permeable to the fluorescent dye Lucifer yellow, even in conditions where electrical conductance is low. These results provide a framework for understanding the operation and functional limits of rectifying electrical synapses, and illustrate that dye permeability can be associated even with their relatively low conductance condition. (22 refs.)

110006 Sustained rise in ACh sensitivity of a sympathetic ganglion cell induced by postsynaptic electrical activities. E.Kumamoto, K.Kuba (Dept. of Physiology, Saga Medical School, Saga, Japan).
Nature (GB), vol.305, no.5930, p.145-6 (8 Sept. 1983).
Long-term alteration in synaptic efficacy found in several neurones of both vertebrates and invertebrates has been suggested as an important mechanism for learning and memory. In bullfrog sympathetic ganglia, acetylcholine (ACh) release from presynaptic nerve terminals is potentiated for a long time by adrenaline through a cyclic AMP system. The authors report a new form of mechanism for long-term synaptic potentiation in sympathetic ganglia, which occurs postsynaptically in a Ca^{2+}-dependent manner. Their results suggest that Ca^{2+} entry into a ganglion cell during repeated action potentials initiates a long-lasting mechanism for the enhancement of a nicotinic ACh action on the subsynaptic membrane. This, as well as the presynaptic mechanism, may contribute to neuronal plasticity in the peripheral autonomic nervous system. (23 refs.)

110007 Hyperpolarization following activation of K^+ channels by excitatory postsynaptic potentials. T.Tosaka, J.Tasaka, T.Miyazaki (Dept. of Physiology, Tokyo Medical Coll., Tokyo, Japan), B.Libet.
Nature (GB), vol.305, no.5930, p.148-50 (8 Sept. 1983).
Reports experiments on the 9th or 10th ganglion in the isolated sympathetic chain of the bullfrog (Rana catesbiana) both with intracellular electrodes (3 M KCl) and with extracellular ones (surface Ag-AgCl wires in an air-gap chamber). The evidence obtained supports the proposal that the post-excitatory postsynaptic potential (e.p.s.p.) hyperpolarization is a voltage-activated response; it is induced when the e.p.s.p. sufficiently depolarizes the membrane, and it can thus 'contaminate' the e.p.s.p. response. The dependence of post-e.p.s.p. hyperpolarization on the amplitude of the e.p.s.p. further indicates that it is a true afterhyperpolarization rather than a separate, transmitter-induced postsynaptic potential; the relationship was seen whether the amplitude of the e.p.s.p. was varied by repetition of input or by curarization. (7 refs.)

110008 Electrical synapse formation depends on interaction of mutually growing neurites. R.D.Hadley, S.B.Kater, C.S.Cohan (Dept. of Zoology, Univ. of Iowa, IA, USA).
Science (USA), vol.221, no.4609, p.466-8 (29 July 1983).
A neuron's competence to form electrical synapses depends on its growth status. Experiments in situ and in cell culture with identified neurons of the snail Helisoma demonstrate that active neurite outgrowth from both potential partners must be spatially and temporally coincident for electrical synapse formation to occur. (14 refs.)

110009 Managing evoked potential data in clinical research. J.R.Boston, B.L.Grundy, E.Doyle (Dept. of Anesthesiology/CCM, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA, USA).
Proceedings of the Fifteenth Hawaii International Conference on System Sciences 1982, Honolulu, HI, USA, 6-8 Jan. 1982 (HI, USA: Hawaii Int. Conference Syst. Sci. 1982), p.254-63 vol.2
During monitoring of sensory evoked potentials, a large number of average potentials are recorded, typically one to ten per hour over a period of several hours. For clinical research, it is necessary to study the sequence of responses retrospectively, extracting a number of parameters from each response that characterize that response and statistically analyzing the changes in the parameters over time. Because of the large number of responses involved, manual analysis of the data is extremely difficult and prone to error. This paper describes a data system developed to eliminate as much manual manipulation and processing of data as possible. A key feature of the system is the definition of data file structures that provide a means of communication within the system, allowing the analysis of the evoked potentials to be implemented as a series of independent modules. (8 refs.)

110010 Linear and nonlinear frequency domain analysis of sensory transduction in an insect mechanoreceptor. A.S.French (Dept. of Physiology, Univ. of Alberta, Edmonton, Alberta, Canada).
Proceedings of the Fifteenth Hawaii International Conference on System Sciences 1982, Honolulu, HI, USA, 6-8 Jan. 1982 (HI, USA: Hawaii Int. Conference Syst. Sci. 1982), p.327-36 vol.2
Coding of information by nerve cells and the relaxed problem of sensory transduction can be investigated by linear and nonlinear systems analysis techniques. An examination of sensory transduction in an insect mechanoreceptor by the measurement of first and second order frequency response functions is described. The results are discussed in light of some current models of mechanotransduction. (34 refs.)

110011 Use of pseudorandom noise in studies of the dynamic properties of the linear part of a sensory neural system. A.R.Moller (Dept. of Otolaryngology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA, USA).
Proceedings of the Fifteenth Hawaii International Conference on System Sciences 1982, Honolulu, HI, USA, 6-8 Jan. 1982 (HI, USA: Hawaii Int. Conference Syst. Sci. 1982), p.337-51 vol.2
The accuracy in determining the bandwidth and the center frequency of a linear bandpass filter followed by a rectifier using pseudorandom noise is investigated. The noise is based on ternary m-sequences. Results obtained using different noise sequences of the same length and sequences of different length were compared. Examples of neurophysiological results on the frequency selectivity of single fibers of the auditory nerve of the rat obtained using pseudorandom noise as stimulus are shown. (13 refs.)

110012 Statistical and dimensional analysis of the neural representation of the acoustic biotope of the frog. P.Johannesma, A.Aertsen (Dept. of Medical Phys. & Biophys., Univ. of Nijmegen, Nijmegen, Netherlands).
Proceedings of the Fifteenth Hawaii International Conference on System Sciences 1982, Honolulu, HI, USA, 6-8 Jan. 1982 (HI, USA: Hawaii Int. Conference Syst. Sci. 1982), p.352-68 vol.2
The field of investigation is the neural representation of acoustic stimuli occurring in the natural environment of the frog. The point of departure is the description of a stimulus ensemble consisting of natural sounds: the acoustic biotope. A relation of statistical and dimensional structure of the acoustic biotope is indicated. The animal used in the neurophysiological experiments is the grass-frog, Rana temporaria L.; micro-electrode recordings are made in the auditory midbrain. A method is described to determine the existence of a relation between acoustic stimulus and neural events. The form of this relation has been investigated by first and second order stimulus-event correlation. While the first one does not give significant results, the second one leads to the spectro-temporal receptive field of the neuron for natural stimuli. Questions are formulated to estimate the value of this receptive field as a functional descriptor of the neuron. Finally an outline is sketched for a synthetic construction of the bio-acoustic space from neuro-acoustic sub-spaces. (42 refs.)

110013 Fibrillation recognition using autocorrelation analysis. A.E.Aubert, B.G.Denys, H.Ector, H.De Geest (Div. of Cardiology, Katholieke Univ. Leuven, Leuven, Belgium).
Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.477-80
Correlation analysis is a powerful technique to determine the similarity between events and to distinguish signal and noise in a composite waveform. The autocorrelation function gives information on typical periods or frequencies present in the time history records. These characteristics were used for ECG analysis in the control situation and during the onset of ventricular fibrillation. (14 refs.)

87.32 PHYSIOLOGICAL OPTICS, VISION

110014 Does reduction of intraocular pressure (IOP) prevent visual field loss in glaucoma?. D.M.Cockburn (Dept. of Optometry, Univ. of Melbourne, Parkville, Victoria, Australia).
Am. J. Optom. & Physiol. Opt. (USA), vol.60, no.8, p.705-11 (Aug. 1983).
The visual fields of 54 eyes (27 patients) having a medical diagnosis of open-angle glaucoma and receiving treatment were compared with the visual fields recorded at the time of diagnosis of the disease. Visual fields remained stable in 34 (62%) of the glaucomatous eyes. However, reduction of the intraocular pressure (IOP) did not prevent the progression of existing field defects in 16 of 21 eyes nor prevent field damage from occurring in 4 of 33 eyes which had normal visual fields at the commencement of treatment. The presence of a visual field defect at the time of diagnosis was clearly associated with a high risk of continued field decay during treatment. Intraocular pressure at the time of diagnosis did not identify which eyes would develop visual field loss or suffer further loss despite hypotensive treatment. Likewise, the extent to which the IOP was reduced by treatment did not appear to be related to the decay of visual field. (16 refs.)

110015 Concepts of biostereometrics applied to robotics. A.Filo (Cyberanimation Inc., Akron, OH, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.346-52 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
By examining the concepts of natural vision, a noncomputer image processor was developed. This device uses a cellular contrast pattern matching and searching technique to define elements of the image. Coupling the pattern matching and searching technique with a stereometric capability provides considerable information about the shape, size, orientation, depth and location of a subject. This type of information is very useful in machines and robots that must acquire objects in unpredictable orientations or in unknown environments. (7 refs.)

110016 Progression of myopia in youth: age of cessation. D.A.Goss (Coll. of Optometry, Northeastern State Univ., Tahlequah, OK, USA), R.L.Winkler.
Am. J. Optom. & Physiol. Opt. (USA), vol.60, no.8, p.651-8 (Aug. 1983).
Patient records of young myopes were collected from three optometry practices. An index of the age at which increases of myopia in young people cease was derived using four different graphical and statistical methods. The results suggest that myopia stops increasing earlier in females than in males. There is, however, a great deal of individual variability in cessation age. Some implications for clinical practice and clinical research are discussed. (13 refs.)

110017 Orthoptic treatment of subjects showing slow accommodative responses. W.R.Bobier, J.G.Sivak (School of Optometry, Univ. of Waterloo, Waterloo, Ontario, Canada).
Am. J. Optom. & Physiol. Opt. (USA), vol.60, no.8, p.678-87 (Aug. 1983).
Five subjects showing slow accommodative responses were given orthoptic treatment. Speed of accommodative response improved after 3 to 6 weeks. No regressions were evident 18 weeks after the cessation of training. Slow accommodative responses were found in subjects with normal phorias and fusion limits. The technique of dynamic photorefraction is introduced for the clinical measurement of accommodative time characteristics. (8 refs.)

110018 Clinical evaluation of vertical fixation disparity. I. R.P.Rutstein, J.B.Eskridge (School of Optometry, Univ. of Alabama, Medical Center, Birmingham, AL, USA).
Am. J. Optom. & Physiol. Opt. (USA), vol.60, no.8, p.688-93 (Aug. 1983).
The successful prescribing of vertical prism for the individual patient requires that (1) the deviation be measured in the presence of horizontal fusion, (2) the deviation be determined with distance and near fixation in the straight ahead and down-gaze positions, and (3) the ability to adapt to the prism be assessed. This study addresses the first requirement by evaluating the measurement of fixation disparity of asymptomatic patients using a readily available clinical procedure. The results indicate that the vertical fixation disparity varies directly and in a consistent manner with forced vertical vergence in patients with no vertical fixation disparity as well as in those with a vertical fixation disparity with zero forced vertical vergence. The implication of this information for the prescription of vertical prism is discussed. (13 refs.)

110019 Amplitude variability of the steady-state visual evoked response (VER). R.L.Yolton (Pacific Univ., Coll. of Optometry, Forest Grove, OR, USA), R.G.Allen, R.A.Goodson, D.L.Schafer, W.D.Decker.
Am. J. Optom. & Physiol. Opt. (USA), vol.60, no.8, p.694-704 (Aug. 1983).
The reliability of steady-state VERs was determined for nine normal subjects using Fourier analyses with 1.0 and 0.25 Hz bin resolutions. No correlations were found between VER amplitudes and subjects' reports of attention, accommodation, fixation, or perceived organization of the stimulus. Across subjects, there was also no sustained amplitude modulation of the VER by any frequency (including alpha), and frequency drift of the VER did not contribute significantly to its amplitude variability. Modeling, using mixed sine waves to simulate different signal/noise ratios, established that a significant portion of VER amplitude variability can be accounted for by noise which occurs at the same frequency as the VER and which is not removed by ensemble averaging. (40 refs.)

110020 Dynamics of cover test eye movements. E.Peli, G.McCormack (New England Coll. of Optometry, Boston, MA, USA).
Am. J. Optom. & Physiol. Opt. (USA), vol.60, no.8, p.712-24 (Aug. 1983).
The dynamics of unilateral cover test eye movements, never before systematically investigated with an objective recording system, are shown to be more complex than textbook accounts of them. The authors administered the cover test to nine heterophoric subjects by means of electromechanical occluders. Eye movements were recorded using the infrared photoelectric technique. Saccadic and vergence movements of the fixating eye were observed in almost all records when the occluded eye was uncovered. These movements were found in esophores and exophores and in both large and small phoria cases. Such movements were previously described in other asymmetric vergence tasks and appear to obey Hering's law of equal innervation. Uncovering the dominant eye, in cases of clear dominancy, resulted in shorter latency and larger amplitude saccades than did uncovering the nondominant eye. (18 refs.)

110021 An analogue simulation of the luminosity-channel in the vertebrate cone retina. II. Frequency analysis. R.Siminoff (Inst. fur Physiologie, Freien Univ. Berlin, Berlin, Germany).
Biol. Cybern. (Germany), vol.47, no.2, p.71-6 (1983).
For pt.I see ibid., vol.46, no.2, p.101 (1983). A frequency analysis was performed on an analogue model of the vertebrate cone retina. Bode plots of magnitude and phase angle shifts were obtained from the various stages of the model. While the cones were nonlinear, the rest of the model was linear and results could be explained by cascading of lowpass filters with linear summation of antagonistic inputs of differing time constants. The cut-off frequency of the model was determined by the first stage, which was the cone pedicle, while the slope of the db magnitude versus frequency curve increased for each 'synaptic delay' in the pathway. An initial increase in the magnitude of the output voltage at any given stage occurred up to the cut-off frequency and was due to the antagonistic input voltages of differing time courses. Physiological data are discussed in terms of the model. (8 refs.)

110022 An analogue model of the luminosity-channel in the vertebrate cone retina. III. Physiological correlates. R.Siminoff (Inst. fur Physiologie, Freien Univ. Berlin, Berlin, Germany).
Biol. Cybern. (Germany), vol.47, no.2, p.77-85 (1983).
For pt.II see ibid., vol.47, no.2, p.71-6 (1983). A model of the vertebrate cone retina was tested with physiological stimuli. Results confirm previous findings that, except for photoreceptors, the spatial and temporal properties of simulated retinal elements conform to a linear system. The model is consistent with known physiological correlates. Tonic units detect intensity when the light spot is within the center field, while phasic units detect movement across borders of contrast. There is a dynamic balance between the tonic and phasic channels: the tonic channel is favored by a center field input voltage, while the phasic channel is favored by a surround field input voltage to bipolar cells. The ON discharge of the phasic ganglion cell is developed by the excitatory center field input to the depolarizing-center bipolar cell, which has the shortest delay, while the OFF discharge is the result of the excitatory surround field input voltage to the hyperpolarizing-center bipolar cell, which has the longest delay. (35 refs.)

110023 The spatial frequency sensitivity of bipolar cells. D.Attwell (Dept. of Physiology, Univ. Coll. London, London, England), M.Wilson.
Biol. Cybern. (Germany), vol.47, no.2, p.131-40 (1983).
Retinal bipolar cells constitute the output stage of the outer layer of the retina. There are several constraints on the ability of the bipolar cell array to respond to the different spatial frequency components of the visual image, including (i) electrical coupling in the dendritic tree receiving receptor input; (iii) the 'lateral inhibition' mediated by horizontal cells. Using simple mathematical models, the authors derive analytical expressions for the spatial frequency response of the bipolar cell array for the case in which horizontal cells are presynaptic to bipolar cells (feedforward model) and also for the case in which horizontal cells are presynaptic to receptors (feedback model). The results illustrate the importance of the three factors mentioned in determining the bipolar cells' properties. The optimal spatial frequency for stimulating the bipolar cell array, and the range of spatial frequencies transmitted onward to the inner plexiform layer, are thus related to the anatomical and electrical properties of the cells in the outer plexiform layer. (25 refs.)

110024 Event-related potentials during naming and mental rotation. D.T.Stuss, F.F.Sarazin, E.E.Leech, T.W.Picton (Schools of Medicine & Psychology, Univ. of Ottawa, Ottawa General Hospital, Ottawa, Ontario, Canada).
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.133-46 (Aug. 1983).
The biphasic late negative wave (Nx-Ny) evoked during the naming of pictures of objects was investigated in a series of experiments. The monitoring of several possible non-cerebral generators indicated that these components were probably cerebral in origin. The Ny wave differed in scalp distribution from

the preceding CNV. It was unaffected by stimulus duration or by stimulus repetition. The Nx-Ny complex occurred in both a naming task and a mental rotation task. The slow waves following the biphasic negative wave differed significantly between these two tasks. In the mental rotation task, there was a large prolonged negativity in both parietal regions. The Nx wave (at approximately 250 msec) of the biphasic complex may represent the initial registration of the stimulus. The Ny wave (at approximately 420 msec) does not appear to be specifically related to semantic processing. Rather it may index some process involved in initiating the further evaluation of a complex stimulus. The slow waves that follow the biphasic negative complex may reflect the actual perceptual processing of the stimulus. (54 refs.)

110025 Transient visually evoked potentials to the pattern reversal and onset of sinusoidal gratings. G.T.Plant, R.L.Zimmern, K.Durden (Dept. of Neurological Surgery & Neurology, Addenbrooke's Hospital, Cambridge, England).
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.147-58 (Aug. 1983).
Transient visually evoked potentials (VEPs) recorded in response to the contrast reversal and onset of spatially sinusoidal gratings have been investigated. Previous reports of an increase in the latency of the response at higher spatial frequencies have been confirmed but only for spatial frequencies higher than 2 c/deg. At lower spatial frequencies it is suggested that two positive components interact resulting in a departure from a monotonic relationship between latency and spatial frequency. Below 1 c/deg pattern reversal and pattern onset modes of stimulation produced VEPs of similar amplitude and wave form. Above 1 c/deg the amplitude of the pattern onset response peaked at a higher spatial frequency than the response to pattern reversal, and the response was dominated by a negative (N_1) rather than a positive component (P_1). This distinction has been corroborated by investigating the effect of field size variation. The peak amplitudes shifted to a lower spatial frequency with increase in field size but at all field sizes the N_1 component of the pattern onset response peaked at a higher spatial frequency than the other components measured. (33 refs.)

110026 Interocular suppression in adults and infants using anaglyphic stimuli: visually evoked potential measures. J.V.Odom (Dept. of Ophthalmology, West Virginia Univ., Morgantown, WV, USA), M.R.Harter.
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.232-43 (Aug. 1983).
Interocular suppression, assessed by monocular VEP amplitude reduction, was investigated in 3 infants, average age of 3 months, and 8 adults. A dichoptic simultaneous masking paradigm was employed, the two eyes being disassociated by red and green filters which transmitted nonoverlapping wave lengths of light (anaglyphic method). One eye was continuously presented with either darkness, a diffuse green light, or two green dot patterns, containing either 20′ or 80′ dots. The other eye was flashed with either red diffuse light, a red 20′ dot pattern, or a red 80′ dot pattern. In both adults and infants, monocular VEP amplitude was reduced as the size of the continuously presented dots increased (pattern suppression) and a smaller amplitude response occurred when dots of equal size were presented (size-specific suppression). The relative and absolute magnitudes of interocular pattern suppression were similar for adults and infants. However, the relative and absolute magnitudes of size-specific suppression were larger for adults than for infants. Pattern interocular suppression was inferred to be relatively more mature in 3 month olds than size-specific suppression. The relative lack of size-specific suppression suggests a relative immaturity of binocular spatial frequency or size channels. (46 refs.)

110027 Specificity of cortico-cortical connections in monkey visual system. M.S.Livingstone, D.H.Hubel (Dept. of Neurobiology, Harvard Medical School, Boston, MA, USA).
Nature (GB), vol.304, no.5926, p.531-4 (11 Aug. 1983).
When the primate primary visual cortex, area 17, is stained for the mitochondrial enzyme cytochrome oxidase, it shows a striking polka-dot pattern (cytochrome oxidase blobs). Area 18, the second visual area, shows a cytochrome-oxidase pattern of coarse alternating thick and thin stripes running perpendicular to the 17-18 border and separated by lighter (interstripe) regions. The authors show that the thin cytochrome oxidase stripes, and possibly also the thick stripes, in area 18 receive projections specifically from the blobs in area 17, and that the interstripe regions of 18 receive projections from the interblob matrix of area 17. This indicates a specificity of cortico-cortical connections far exceeding the demands of topographical mapping. Together with the authors' physiological results, it suggests that within the pathway from area 17 to area 18 different kinds of information may be handled separately and in parallel. (34 refs.)

110028 Very brief visual experience eliminates plasticity in the cat visual cortex. G.D.Mower, W.G.Christen, C.J.Caplan (Dept. of Neurology, Children's Hospital Medical Center, Boston, MA, USA).
Science (USA), vol.221, no.4606, p.178-80 (8 July 1983).
Rearing cats in the dark extends the critical period for development of visual cortical neurons, which indicates that the experience of visual input is necessary to begin the development process. A single brief pulse of visual input (6 hours) during a period of dark-rearing eliminates delayed development in the visual cortex. Light therefore seems to rapidly trigger the developmental process, and once triggered, that process runs to completion in the absence of further input. (10 refs.)

110029 Evoked potential estimates of visual accommodation in infants. S.Sokol, A.Moskowitz, A.Paul (Dept. of Ophthalmology, Tufts Univ. School of Medicine, Boston, MA, USA).
Vision Res. (GB), vol.23, no.9, p.851-60 (1983).
Pattern reversal visually evoked potentials (VEPs) were recorded from infants between 2 and 5 months of age in order to measure their accommodative performance over a 9 diopter range (10-150 cm). Accommodation was stimulated by placing minus spherical lenses of increasing power in front of the infant's eyes and by changing the infant's distance from the stimulus. VEP latency measurements indicated that the infant's ability to maintain a zone of clear vision changes with age and pattern element size. For large checks (60 min arc), most 2- to 4-month old infants were able to maintain clear vision over the range of 9 diopters. When small checks (15 min arc) were used, the majority of 4- to 5-month old infants were unable by VEP measures to accommodate beyond 5-6 diopters. This decline in the infant's zone of clear vision with decreasing check size is due primarily to the relatively large depth of focus and poor visual resolution of the infant eye. In a small group of infants, accommodation was assessed both electrophysiologically by VEP recording and behaviorally using a preferential looking technique. Results indicated better accommodation by VEP estimates than by behavioral measures. (27 refs.)

110030 Electrophysiological determination of the refractive state of the eye of the opossum. C.W.Picanco-Diniz, L.C.L.Silveira (Dept. of Physiology, Federal Univ. of Para, Rio de Janeiro, Brazil), E.Oswaldo-Cruz.
Vision Res. (GB), vol.23, no.9, p.867-72 (1983).
The refractive state of the eye of the South American opossum Didelphis marsupialis aurita was investigated with electrophysiological techniques. Using adult specimens, trapped from the wild, averaged cortical evoked responses were recorded from the region of projection of the central visual field. Stimuli consisted of a phase reversal of a square wave grating generated on a CRO screen, with luminance of $2.4\ \mathrm{cd/m^2}$ and contrast 0.84. The refractive state of the eye was altered by means of trial lenses and the amplitude of the cortical responses thus obtained compared to those obtained with no lens (control values). Refraction 'tuning curves' were determined for each animal. The average refractive state was found to be -2.27 D indicating that this species when raised in its habitat shows, at low ambient luminosity, some degree of myopia. Determination of the contrast sensitivity function indicate that induced ametropias lead to a reduction of the cut-off value of the spatial frequency and a loss of contrast sensitivity. (36 refs.)

110031 Spatial frequency tuning of orientation selective units estimated by oblique masking. H.R.Wilson, D.K.McFarlane, G.C.Phillips (Dept. of Biophys. & Theoretical Biology, Univ. of Chicago, Chicago, IL, USA).
Vision Res. (GB), vol.23, no.9, p.873-82 (1983).
Threshold elevations were measured as a function of the spatial frequency of high contrast cosine masks using spatially localized test stimuli with a 1.0 octave bandwidth. The cosine masks were oriented at 14.5° relative to the vertical test patterns in order to average out spatial phase effects. The experiment was repeated for each of 14 test frequencies spanning the range 0.25-22.0 c/deg in 0.5 octave steps. The resulting threshold elevation curves fell into a small number of distinct groups, suggesting the existence of discrete spatial frequency mechanisms in human central vision. The data are shown to be consistent with a model having just six distinct classes of spatial frequency mechanisms in the fovea. Spatial frequency bandwidths of these mechanisms ranged from 2.5 octaves at low frequencies to as narrow as 1.25 octaves at high spatial frequencies. These results require revision of the Wilson and Bergen model for spatial vision (see ibid., vol.19, p.19-32, 1979). (38 refs.)

110032 Neural interactions of two slits in the orientation domain in the visual cortical units of the cat. S.Kaji, S.Yamane, N.Kawabata (Electrotech. Lab., Ibaraki-ken, Japan).
Vision Res. (GB), vol.23, no.9, p.883-6 (1983).
The responses of the cat's visual cortical cells to an optimally oriented (O-) and to an inclined (θ-) slit have been studied. Cellular responses to the simultaneous presentation, in simple cells, are similar to those to the θ-slit alone, but in complex cells, are remarkably decreased at an orientation difference of about 45°. In the sequential presentation, the effects of preceding the θ-slit on the responses to the following O-slit decrease as the orientation difference increases. This suggests that neural interactions of simultaneous and sequential presentation of two slits are caused by different mechanisms. (8 refs.)

110033 Two late response components in on-off ganglion cells of the frog retina: the delayed response—generated by red rods; the second off-response—generated by green rods. M.L.Zeise, K.Hamdorf (Lehrstuhl fur Tierphysiologie, Ruhr-Univ., Bochum, Germany).
Vision Res. (GB), vol.23, no.9, p.887-93 (1983).
Frog on-off retinal ganglion cells react to diffuse, large-sized stimuli not only with an 'early response' and a 'delayed response' but also with a 'second off-response'. The intensity at which the delayed response becomes visible coincides with the quantum amount necessary for saturating the red rod response. The spectral sensitivity of the delayed response fits the nomogram for the 502 nm pigment. Unlike the delayed response, the second off-response appears earlier with increasing stimulus intensity and follows the 433 nm nomogram. Therefore, it is most probably generated by the green rods. (20 refs.)

110034 Mode of origin of large extracellular photovoltages from the retinal rods of the frog. W.Ehrhardt, C.Baumann (Physiologisches Inst., Justus Liebig-Univ., Giessen, Germany).
Vision Res. (GB), vol.23, no.9, p.895-902 (1983).
Arrays of extracellular microelectrodes were advanced into the receptor layer of isolated frog retinae to measure interstitial voltage and resistance. In addition, current was locally injected through one of the micro-electrodes and spatial profiles of local resistance were recorded. A large increase of local resistance in the proximal half of the receptor layer was frequently associated with the occurrence of large extracellular voltages arising from rods. The large responses presumably occur at sites where the micropipette tip makes tight contact with membrane processes of the rod inner segment and a quasi-intracellular mode of recording results. 87.32L Light detection; adaptation and discrimination

110035 Dark adaptation and the acuity/luminance response in senile macular degeneration (SMD). B.Brown (Smith-Kettlewell Inst. of Visual Sci., San Francisco, CA, USA), J.L.Kitchin.
Am. J. Optom. & Physiol. Opt. (USA), vol.60, no.8, p.645-50 (Aug. 1983).
Patients with SMD often complain of problems with adaptation and have best acuity under a restricted range of lighting conditions. The authors investigated dark adaptation and acuity over a wide range of luminances in eight SMD patients and six age-matched controls. Some patients showed evidence of altered dark adaptation, with a much longer time required to reach asymptotic sensitivity levels than shown by normals; others had difficulty with spatial resolution at different light levels. There was good correlation between symptoms and test findings; all but one patient who reported difficulties with adaptation demonstrated either retarded adaptation, aberrant acuity/luminance response, or both. These data provide evidence that the processes which adjust the sensitivity of the retina and the spatial summation properties of the retina are disrupted in SMD. (12 refs.)

110036 Processing of polarized light by squid photoreceptors. W.M.Saidel (Dept. of Anatomy, Georgetown Univ., Washington, DC, USA), J.Y.Lettvin, E.F.MacNichol,Jr..
Nature (GB), vol.304, no.5926, p.534-6 (11 Aug. 1983).
Behavioural tests have demonstrated that cephalopods can discriminate light polarized in different planes, and the receptors have been localized by electro-

physiological studies of the eye. Discrimination of the plane of polarization is a consequence of both the structure of the microvilli in the outer segments of the photoreceptors and the orientation of the photosensitive chromophore on these membranes. However, between the depolarizing receptor response resulting from photoreception and the behaviour of the animal, nothing is known about neuronal processing of polarized light by cephalopods. The authors show that some squid photoreceptors discriminate the plane of polarization within the spike train, and that any particular plane is seen as a variable intensity. Given the well known orthogonal orientation of microvilli in outer segments of adjacent photoreceptors and the physiological preference for one of two mutually perpendicular planes of polarization by single photoreceptors, the authors conclude that cephalopod vision is based on two complementary views of the world, each determined by the transformation of polarization-sensitive receptors into complementary intensity scales. A visual system based on this transformation would lead to enhanced contrast underwater and visualization of object details obscured by confounding highlights. (31 refs.)

110037 Inhibitory influence of unstimulated rods in the human retina: evidence provided by examining cone flicker. S.H.Goldberg, T.E.Frumkes, R.W.Nygaard (Dept. of Psychology, Queens Coll., City Univ. of New York, Flushing, NY, USA).
Science (USA), vol.221, no.4606, p.s180-2 (8 July 1983).
In the parafoveal retina of human observers, cone-mediated sensitivity to flicker decreases as rods become progressively more dark-adapted. This effect is greatest when a rod response to flicker is precluded. These results indicate that rods tonically inhibit cone pathways in the dark. (24 refs.)

110038 Flicker fusion characteristics of rod photoreceptors in the toad. L.M.Nowak, D.G.Green (Neuroscience Lab., Univ. of Michigan, Ann Arbor, MI, USA).
Vision Res. (GB), vol.23, no.9, p.845-9 (1983).
Critical fusion frequency (CFF) of toad rods was examined at various intensities using intracellular recordings. Data were compared to CFF measurements (as a function of intensity) obtained with the electroretinogram (ERG) and with a horizontal cell. In all instances the rod (and rod mediated) responses produced a curve which increased monotonically to a high frequency asymptote at about 6 Hz. The curves obtained with the ERG and the horizontal cell were double branched. The upper branch exhibited a Purkinje shift and thus must have been produced by cones. Even when using a red background to suppress cone sensitivity, there was no sign of a second rod mediated branch in the CFF curves from this retina. (15 refs.)

110039 Comparison of means and medians in the reduction of visual evoked potential data. J.A.Comis,Jr. (Dept. of Electrical Engng. & Computer Sci., Univ. of California, Berkeley, CA, USA), E.Marg, D.R.Brillinger, D.P.Rudiak, E.L.Keller.
Proceedings of the Fifteenth Hawaii International Conference on System Sciences 1982, Honolulu, HI, USA, 6-8 Jan. 1982 (HI, USA: Hawaii Int. Conference Syst. Sci. 1982), p.242-53 vol.2
Means and medians of visual evoked potentials were compared to determine if the medians would provide less noisy results than the means or require fewer samples for the same noise. The means and medians of a 100 onset-offset checkerboard VEPs were computed and plotted for (1) the full sample, (2) the first and second 50, and (3) the first 25. In addition, running means were examined. Comparable means showed less scatter than the medians. A N_{340} wave was seen in the mean of the second 50 VEPs not observable in the first 50. A running mean of 3 gives a curve as useful as the mean of 100 with only 50 VEPs within the first 250 msec. Samples of 25 VEPs are not adequate to provide a useful waveform but may be used to determine economically the peak amplitude with a potential error of less than 4%. This can be useful in the objective measurement of visual acuity. (10 refs.)

110040 Macular pigment difference spectrum from sensitivity measures of a single cone mechanism. P.L.Pease (Coll. of Optometry, Univ. of Houston, Houston, TX, USA), A.J.Adams.
Am. J. Optom. & Physiol. Opt. (USA), vol.60, no.8, p.667-72 (Aug. 1983).
The authors have obtained the difference spectrum for the macular pigment by comparing the spectral sensitivity of the 'green-sensitive' or G cone mechanism in the foveal and parafoveal region. The method overcomes objections to previous attempts to obtain a difference spectrum from the spectral sensitivities by isolating a single receptor mechanism; it also provides a relatively easy approach for obtaining a reliable measure of the optical density of the macular pigment for individual subjects. The results using this method suggest a higher optical density for the macular pigment than that obtained from data where more than one cone type influenced the difference spectrum. (20 refs.)

110041 Quantum optimality of day vision and photocolorimetry. M.P.Filippov, A.A.Ovchinnikov (L.Ya. Karpov Sci.-Res. Physicochem. Inst., Moscow, USSR).
Dokl. Biophys. (USA), vol.265-267 (July-Dec. 1982)., p.146-9
The quantum optimality of day vision, a feature that the authors have discovered, has the nature of an extreme biological principle and can be used to replace the classical energy-based concepts of contemporary photocolorimetry by new quantum concepts in this field. The authors discuss the evidence supporting their ideas. (7 refs.)

110042 Leaf color used by cabbage root files to distinguish among host plants. R.J.Prokopy, R.H.Collier, S.Finch (Nat. Vegetable Res. Station, Wellesbourne, England).
Science (USA), vol.221, no.4606, p.190-2 (8 July 1983).
In experiments in which spectrophotometric reflectance patterns of real leaves were mimicked with mixtures of artists' pigments, leaf color was shown to be a character used by cabbage root flies, before landing on leaves, to discriminate among the host plant cultivars radish, green cabbage, and red cabbage. It may be possible to take advantage of factors that affect leaf color, such as epicuticular bloom, pubescence, and masking of chlorophyll by other pigments, to decrease the attraction of certain pest insects to plants. (22 refs.)

110043 Dark adaptation of the long-wavelength sensitive cones. A.M.Brown (Vision Res. Lab., Univ. of Michigan, Ann Arbor, MI, USA).
Vision Res. (GB), vol.23, no.9, p.837-43 (1983).
Long-wavelength sensitive (L) cone dark adaptation curves were measured with a 10-msec, 20′ v.a., 650 nm test flash and a moderate intensity adapting field. When the 650 nm and 500 nm fields were equated for the L cones, the dark adaptation curve fell faster for the 500 nm field than for the 650 nm field. Over the range of adapting lights used, no adjustment of the intensities of the two fields made their dark adaptation curves similar. When 500 nm light was added to the 650 nm field, dark adaptation was faster. Visual sensitivity is not regulated by any single photoreceptor type in this experiment. (16 refs.)

87.32S Psychophysics of vision, visual perception, binocular vision

110044 Perceptual organization in moving patterns. V.S.Ramachandran (Dept. of Psychology, Univ. of California, San Diego, La Jolla, CA, USA), S.M.Anstis.
Nature (GB), vol.304, no.5926, p.529-31 (11 Aug. 1983).
Is human motion perception based on a local piecemeal analysis of the image or do global effects play an important role? The authors used metastable apparent motion displays to try to answer this question. Two spots were flashed simultaneously on diagonally opposite corners of a square and then switched off and replaced by two spots appearing on the remaining corners. One could either see vertical or horizontal oscillation of the spots and the display was bistable just as a Necker cube is. The authors found that if several such bistable figures were randomly scattered on the screen, and presented simultaneously, then one always saw the same motion-axis in all of them, suggesting the presence of global field-like effects for resolving ambiguity in apparent motion. Surprisingly, the appearance of these displays could not be influenced by voluntary effort unless the speed of alternation was very slow. (Less than 3 frames per second.) It may be that if the events in the module that computes apparent motion are too rapid then it cannot be coupled with the 'will' mechanism, which may have a long time constant. (11 refs.)

110045 Added noise restores recognizability of coarse quantized images. M.C.Morrone, D.C.Burr, J.Ross (Dept. of Psychology, Univ. of Western Australia, Nedlands, Australia).
Nature (GB), vol.305, no.5931, p.226-8 (15 Sept. 1983).
When a portrait is coarsely quantized into blocks, the block structure hides the face, although lower spatial frequencies of the original image sufficient by themselves for recognition are preserved. Recognition can be recovered by blurring the image, or otherwise attenuating the spurious higher spatial frequency components. Harmon and Julesz (1973) claim that high spatial frequencies introduced by quantized blocking mask the lower spatial frequencies which convey information about the face, preventing recognition. Here the authors show that recognition can be enhanced, without decreasing the amplitude of these spurious higher frequencies, by adding further high-frequency noise to the quantized image. This result is clearly at odds with a theory of high-frequency (or critical band) masking. The authors suggest that the added noise mutes mechanisms which would otherwise impose a block structure on the image, allowing the alternative perceptual organization of the hidden face to reemerge. (11 refs.)

110046 Accurate visual measurement of three-dimensional moving patterns. J.S.Lappin, M.A.Fuqua (Dept. of Psychology, Vanderbilt Univ., Nashville, TN, USA).
Science (USA), vol.221, no.4609, p.480-2 (29 July 1983).
Human observers discriminated relative three-dimensional distances in simple patterns of motion parallax with an acuity similar to vernier acuity under comparable conditions. Accurate visual measures of three-dimensional distance can be derived from the structural invariance of patterns undergoing perspective transformations. (8 refs.)

110047 Contrast sensitivity for vertically and obliquely oriented gratings as a function of grating area. J.S.Tootle, M.A.Berkley (Dept. of Psychology, Florida State Univ., Tallahassee, FL, USA).
Vision Res. (GB), vol.23, no.9, p.907-10 (1983).
Contrast sensitivity for both vertically and obliquely oriented gratings increased with increases in stimulus area to an asymptotic value. Sensitivity grew more slowly for oblique gratings and reached an asymptotic value at a larger area than for vertical gratings. For equal areas, oblique gratings always yielded poorer sensitivity. The results suggest a larger spatial summation area for obliquely oriented gratings. (12 refs.)

110048 Inhibition and facilitation of apparent motion by real motion. M.Green (Neurologische Klinik mit Abteilung Fur Neurophysiologie, Albert Ludwig Univ., Freiburg, Germany).
Vision Res. (GB), vol.23, no.9, p.861-5 (1983).
Observers viewed a CRT display which contained both real and apparent motion. When the apparent motion was in the same direction as the real motion, the strength of the apparent motion was enhanced. Real motion in the opposite direction completely cancelled apparent motion. However, the appearance of the real motion was not affected by apparent motion. (18 refs.)

110049 Sleep and the McCollough Effect. N.J.Lund, D.M.MacKay (Dept. of Communication & Neurosci., Univ. of Keele, Keele, England).
Vision Res. (GB), vol.23, no.9, p.903-6 (1983).
Orientation-contingent chromatic ('McCollough') aftereffects (OCCAs) were induced under carefully standardised conditions, in subjects suffering from varying degrees of sleep deprivation. The initial OCCA strength was found to vary systematically with the prior sleep pattern of the subject. In subjects whose sleep normally lasted 7-8 hr, loss of 3 or 4 hr of the previous night's sleep could reduce initial strength by a much as 50%; no further reduction was observed with still shorter sleep durations. Keeping the eye in darkness while awake had in this respect no comparable effects to those of sleep, and sleeping in a lighted room made no difference. The results suggested that the McCollough Effect depends on a form of neural plasticity which requires a normal sleep cycle for its maintenance. (12 refs.)

110050 The retinal binocular field of he pigeon (Columba livia: English Racing Homer). G.R.Martin, S.R.Young (Dept. of Zoology & Comparative Physiology, Univ. of Birmingham, Birmingham, England).
Vision Res. (GB), vol.23, no.9, p.911-15 (1983).
An ophthalmoscopic reflex technique has shown that in sedated pigeons maximum retinal binocular field width occurs approximately 20° above the bill. The binocular field has a maximum width of 27° and extends vertically by 130° (90° above the bill, 40° below it). Both the bill and cere intrude into the binocular field. Maximum optical binocularity also occurs approximately

20° above the bill. The plane containing the optic axes of each eye coincides with the bill. (14 refs.)

110051 The meaning of non-monotonic psychometric functions in the assessment of infant preferential looking acuity. A reply to Banks et al. (1982) and Teller et al. (1982). J.M.Wolfe, J.Gwiazda, R.Held (MIT, Cambridge, MA, USA).
Vision Res. (GB), vol.23, no.9, p.917-20 (1983).
The authors' version of preferential looking (PL) reliably produces steep, non-monotonic psychometric functions in infants up to 1 year of age. The methods of Banks et al. (see ibid., vol.22, p.1025-32, 1982) and Teller at al. (see ibid., vol.22, p.1017-24, 1982) reliably produce shallower but monotonic functions in infants up to six months of age. All methods so far used document the increase in PL acuity with age and all can be used to give an estimate of the PL acuity of an infant. The choice of psychophysical methodology is constrained by knowledge or lack of knowlege about the shape of the underlying psychometric function. If one knows the function is monotonic, standard staircase methods work well. If one knows there is a dip, the method proposed in Gwiazda et al. (1980) is appropriate. If one knows nothing, the method of constant stimuli is probably the safest course. Finally, the existence of reliable negative preferences in the authors' data demonstrates that PL, though exceedingly useful, must be used with care. One is inferring the properties of infant vision by observing infant behavior. One should not fall into the trap of presuming to know the nature of infant preferences for a set of stimuli before one has examined those preferences. (11 refs.)

87.34 AUDITION

110052 Use of pseudorandom noise in studies of frequency selectivity: the periphery of the auditory system. A.R.Moller (Dept. of Otolaryngology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA, USA).
Biol. Cybern. (Germany), vol.47, no.2, p.95-102 (1983).
Frequency selectivity of single auditory nerve fibers in the rat are studied using pseudorandom noise based on ternary *m*-sequences as the stimulus, and the results are compared to those of earlier studies in which noise based on binary *m*-sequences was used. Pseudorandom noise based on ternary *m*-sequences has fewer anomalies than noise based on binary *m*-sequences. Detailed tests using linear and nonlinear filters show that the present method provides accurate measures of bandwidth and center frequency. Period histograms of the response, locked to the periodicity of the noise, are cross-correlated with one period of the noise to obtain estimates of the impulse response function of the peripheral auditory system. Fourier transforms of these cross-correlograms used as estimates of the filter function of single auditory nerve fibers. The results obtained using ternary noise are not different from previous results showing a downward shift in center frequency and increase in bandwidth with increasing stimulus intensity for fibers with center frequencies between 1000 and 5000 Hz. The difference between spectral selectivity based on discharge rate is discussed. (39 refs.)

110053 Stimulus dependent neural correlations in the auditory midbrain of the grassfrog (Rana temporaria L). J.J.Eggermont, W.J.M.Epping, A.M.H.J.Aertsen (Dept. of Medical Phys. & Biophys., Univ. of Nijmegen, Nijmegen, Netherlands).
Biol. Cybern. (Germany), vol.47, no.2, p.103-17 (1983).
Few-unit recordings were obtained using metal microelectrodes. Separation into single-unit spike trains was based on differences in spike amplitude and spike waveform. For that purpose a hardware microprocessor based spike waveform analyser was designed and built. Spikes are filtered by four matched filters and filter outputs at the moments of spike occurrence are read by a computer and used for off-line separation and spike waveform reconstruction. Thirty-one double unit recordings were obtained and correlation between the separated spike trains was determined. After stimulus correction correlation remained in only 8 of the double unit records. It appeared that in most cases this neural correlation was stimulus dependent. Continuous noise stimulation resulted in the strongest neural correlation remaining after correction for stimulus coupling, stimulation with 48 ms duration tonepips presented once per second generally did not result in a significant neural correlation after the correction procedure for stimulus lock. The usefulness of the additive model for neural correlation and the correction procedure based thereupon is discussed. (41 refs.)

110054 Maturation of the auditory brain stem response in rhesus monkeys (Macaca mulatta). W.J.Doyle, M.M.Saad, T.J.Fria (Dept. of Otolaryngology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA, USA).
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.210-23 (Aug. 1983).
To document the maturational changes in the auditory brain stem response (ABR) of the rhesus monkey, longitudinal and cross-sectional data were collected on a panel of 31 animals during the first year of life. Each ABR test consisted of averaging 2048 responses to click stimuli delivered at a rate of 21 clicks/sec and elicited at 60, 40, 20 and 10 dB HL intensities in accordance with procedures described previously. The morphology of the ABR wave form recorded at birth was similar to that at 12 months of age and the latencies of the component waves decreased exponentially over this period. The magnitude of decrease in latency was greatest for wave IV and least for wave I. The changes were similar in pattern to those reported for human data and suggest that the rhesus monkey may serve as an appropriate model of auditory development in man. (14 refs.)

110055 Comparison of the latencies between bone and air conduction in the auditory brain stem evoked potential. E.H.J.F.Boezeman (Dept. of Clinical Neurophysiology, Valeriuskliniek & Academic Hospital, Free Univ., Amsterdam, Netherlands), T.S.Kapteyn, S.L.Visser, A.M.Snel.
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.244-7 (Aug. 1983).
Brain stem auditory evoked potentials obtained by air and bone conduction were investigated in 22 subjects. The necessity for a carefully selected stimulus being presented to the headphone and the bone vibrator is discussed. Latency values of both responses are presented for wave V. Bone conduction showed latencies which were longer than those obtained by air conduction (about 0.9 msec). Possible mechanisms for this delay are discussed. (9 refs.)

110056 The spectral factor in noise-induced hearing loss: a case for retaining the A-weighting. D.W.Robinson (Inst. of Sound & Vibration Res., Univ. of Southampton, Southampton, England).
J. Sound & Vib. (GB), vol.90, no.1, p.103-27 (8 Sept. 1983).
For the measurement of industrial noise in hearing conservation, majority usage including international standard practice favours the A-weighting. Any change would have important practical consequences and wide administrative repercussions, but direct validation of this frequency weighting through comparisons of persistent threshold shift (PTS) is lacking. Data from the study of hearing and noise in industry by Burns and Robinson (1970) are re-examined, paying particular attention to the age and noise exposure equivalence of groups of subjects classified by spectrum slope and shape. The results for 101 subjects exposed to 47 different noises fail to reveal significant advantage of the A-weighting over other standardized frequency weightings, a conclusion which may be read as a justification for continued use of the former. The real lesson to be learnt from this analysis is that the possibility of clear-cut determination of an optimum frequency weighting is remote. It would be attainable only through a more extensive bank of data of high reliabiity covering a wider spectral range, and this does not appear to exist at present. (18 refs.)

110057 Relation between cross-correlation coefficient of two-channel acoustic signals and sound image quality.. K.Kurozumi, K.Ohgushi (NHK Broadcasting Sci. Res. Labs., Tokyo, Japan).
J. Acoust. Soc. Jpn. (Japan), vol.39, no.4, p.253-60 (April 1983). In Japanese.
In order to investigate sound image quality, white or band-limited noises with various degrees of the cross-correlation coefficient are reproduced from two loudspeakers placed in anechoic or echoic chambers. Subjects are asked to make similarity judgments and some subjective evaluations of pairs of the noises. The experimental data are analyzed by Kruskal's multidimensional scaling (MDS) program (1964). The analysis of the experimental data shows the following: (1) sound image quality depends mostly on the width and distance of sound image; (2) the width of sound image depends on the absolute value of the cross-correlation coefficient; (3) the distance of sound image depends on the value itself of the cross-correlation coefficent; and (4) with respect to physical and physical and psychological factors governing sound image quality, there is no fundamental difference between anechoic and echoic chambers. (20 refs.)

110058 Frequency tuning in a frog vestibular organ. J.F.Ashmore (School of Biological Sci., Univ. of Sussex, Brighton, England).
Nature (GB), vol.304, no.5926, p.536-8 (11 Aug. 1983).
Reports that in the frog saccule, a vestibular organ apparently constructed for the detection of vibratory accelerations, frequency tuning may arise from an electrical resonance intrinsic to the hair cells. The mechanism is similar to that found in turtle and ensures that a stimulus with frequency corresponding to the membrane resonant frequency will produce the largest signal in the cell. This type of tuning may thus be quite widespread. Oscillatory mechanisms have been reported in sensory cells of other modalities in several lower vertebrates, and may even contribute to their sensitivity, although such mechanisms do imply that the signal-to-noise ratio is degraded near threshold. (21 refs.)

110059 Voltage- and ion-dependent conductances in solitary vertebrate hair cells. R.S.Lewis, A.J.Hudspeth (Div. of Biology, California Inst. of Technol., Pasadena, CA, USA).
Nature (GB), vol.304, no.5926, p.538-41 (11 Aug. 1983).
An important function of the peripheral auditory system is the resolution of complex sounds into their constituent frequency components. In at least one auditory organ, the turtle cochlea, frequency tuning is greatly enhanced by the electrical properties of the hair-cell membrane; each cell in this organ behaves as an electrical resonator tuned to a narrow band of frequencies. Using the 'Gigaseal', whole-cell recording technique, the authors have investigated the biophysical basis of similar resonant behaviour in enzymatically isolated hair cells from the bullfrog sacculus. They report the identification of three voltage- and ion-dependent conductances which may contribute to the electrical tuning mechanism: a non-inactivating calcium conductance, an A-type K^+ conductance, and a Ca^{2+}-activated K^+ conductance. 110060 On semantic information in a speech recognition system for Japanese sentences. Y.Sekiguchi, M.Shigenaga (Faculty of Engng., Yamanashi Univ., Kofu, Japan).
Trans. Inst. Electron. & Commun. Eng. Jpn. Part D (Japan), vol.J66D, no.6, p.629-36 (June 1983). In Japanese.
Semantic information in a speech recognition system for continuously spoken Japanese sentences is described. A case structure is used to represent meaning of each verb, and words with similar semantic features are bundled into each specified group in every part of speech. The effectiveness of use of semantic information for prediction of candidate words has been confirmed. The system constructs a semantic network of episode combining recognized sentences successively. The system can successfully recognize 34 and 30 sentences out of 44 sentences, which describe four Japanese fairy tales, for each case with vocabularies of 204 and 503 words respectively. (14 refs.)

110061 Scalp recorded somatosensory evoked potentials to posterior tibial nerve stimulation in humans. C.L.Vera, P.L.Perot,Jr., E.L.Fountain (Dept. of Neurological Surgery, Medical Univ. of South Carolina, Charleston, SC, USA).
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.159-68 (Aug. 1983).
The somatosensory evoked potentials (SEPs) produced by stimulation of the right and left posterior tibial nerves individually and also by their simultaneous stimulation were recorded in 84 adult normal subjects up to 150 msec after the stimulus by electrodes placed on the cranial vertex and by rows of electrodes over the sagittal and coronal lines using references on the ear or in the nasopharynx. The statistical distribution of the latencies of their different peaks was established. The effect of simultaneous stimulation of right and left posterior tibial nerves on the early SEP components was described. Some details of the anatomy of the rolandic sulcus were inferred from the amplitude distribution of these potentials. (42 refs.)

110062 Median nerve evoked potential changes in an acute carpal tunnel syndrome model in Macaca mulatta. R.J.Schneider, A.L.Dellon (Lab. of Neurosci., Maryland Inst. for Emergency Medical Services Systems, Baltimore, MD, USA).
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.224-31 (Aug. 1983).
The authors devised an acute, carpal tunnel syndrome (CTS) model in rhesus monkey, Macaca mulatta. This model was used to observe the relationship between increases in compartmental pressure and nerve function as reflected in the electrophysiologically generated, averaged evoke potential recorded from the skin superficial to the median nerve at the elbow. Two waves, an Aβ and Aδ were monitored. Increased carpal tunnel pressure produced a decrease in the Aβ wave amplitude which was occasionally preceded by a slight elevation, but which eventually resulted in Aβ wave abolition with pressures ≥ 31 mm Hg. The Aδ wave showed an initial increase in amplitude followed by a decline and abolition. Recovery rate from increased pressure for the Aβ wave was directly proportional to the rate of abolition of that wave. The implications of these data are discussed in the context of CTS neuropathology and diagnosis. (43 refs.)

110063 High-resolution recordings of the magnetic activity of the His-bundle in man. S.N.Erne, R.R.Fenici, H.D.Hahlbohm, H.P.Lehmann, Z.Trontelj (Physikalisch-Tech. Bundesanstalt, Inst.-Berlin, Berlin, Germany).
Nuovo Cimento D (Italy), vol.2D, ser.1, no.4, p.1110-18 (July-Aug. 1983).
The activity of the His-Purkinje system (HPS) in man has been measured magnetically with a SQUID magnetometer in the Berlin magnetically shielded room (BMSR) by using in addition band pass filtering (band width 0.5 Hz to 300 Hz) and averaging. The MBSR reduces the background noise level to less than $4\ \mathrm{fT}/\sqrt{\mathrm{Hz}}$ in the region of white noise. Within the *PR* interval a ramp pattern was observed, changing its slope when crossing the median line of the heart. In addition, definite signals were recorded approximately 40 ms before the onset of ventricular activation. (13 refs.)

110064 Biomagnetic geomagnetism. J.L.Kirschvink (Div. of Geological & Planetary Sci., California Inst. of Technol., Pasadena, CA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.672-5 (April 1983).
Discusses magnetite biomineralisation, rock magnetism, palaeomagnetism, geomagnetism and animal behaviour. (65 refs.)

87.45 BIOMECHANICS, BIORHEOLOGY, BIOLOGICAL FLUID DYNAMICS

110065 On the landing response of the blowfly, Calliphora erythrocephala. H.Eckert (Philipps-Univ. Marburg, Marburg, Germany).
Biol. Cybern. (Germany), vol.47, no.2, p.119-30 (1983).
The dependence of the landing response on the direction of moving stimuli (periodic gratings, single or double stripes) was studied in blowflies, Calliphora erythrocephala, of both sexes. Directions of motion eliciting maximally strong responses (preference direction) vary with the eye region stimulated: they are distributed radially from a common origin forming a flow-field. This origin lies at the intersection of the eye equators with the median plane of the animal. By changing its body posture relative to the direction of flight, the fly may align the pole of this flow field with its direction of flight thus maximizing signal flow for the landing approach. Sex-specific differences were found for dorsal eye regions in which the shift of preference directions from vertical to obliquely inclined directions of motion (against the median plane) could only be determined for male flies. (41 refs.)

110066 Bladder stretch during increase in abdominal pressure. S.Plevnik (Inst. 'J. Stefan', Univ. 'E. Kardelj', Ljubljana, Yugoslavia).
Clin. Phys. & Physiol. Meas. (GB), vol.4, no.3, p.315-20 (Aug. 1983).
The circumference of single bladder projections (CBP) was estimated from oblique and lateral cystographs obtained in the supine and erect positions during both rest and straining, with and without electrical stimulation of the pelvic floor. The results obtained indicate an increase of CBP and a flattening of the bladder during an increase of abdominal pressure, and a decrease of CBP during electrical stimulation. Increase of CBP means an increase in the stretching of the bladder wall, which may produce an increase in the forces in the bladder wall and hence act to open the bladder neck. The decrease of the CBP during electrical stimulation of the pelvic floor indicates that the pelvic floor support reduces flattening of the bladder and hence limits the development of the bladder wall stretch. (no refs.)

110067 Importance of biostereometrical techniques in analyzing the gestures performed in two distinct environments: air and water. G.Ignazi, R.Mollard, J.C.Pineau (Lab. d'Anthropologie Appliquee, Univ. Rene Descartes, Paris, France).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.267-74 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A biostereometric method for analysis of gestures has been developed to study the influence of an aqueous environment on the biomechanical behaviour of man. Developed power and time of execution data were collected for different test conditions, in air and water. By 3-D analysis, the phases of movement (flexion-extension of the upper limb) were reconstituted and the displacements of each segment were calculated. The influence of the aqueous environment on the execution of gesture and the effect of thrust and ballast in water are described. (7 refs.)

110068 Temporal resolution requirements for the double stance period of human gait [high speed cinematography]. J.U.Baumann, P.Procter, A.Schaer (Dept. of Surgery, Univ. of Basel, Children's Hospital, Basel, Switzerland).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.288-92 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Study of transient force phenomena in the double stance period of normal gait suggests that high temporal resolution is required in concommittant movement analysis. The study described concludes that at least 300 pictures per second are necessary to resolve kinematic transients associated with heel strike. (13 refs.)

110069 Moments about body centered coordinate axes at limb joints from force plate and biplane photography measurements. S.Balakrishnan, A.B.Thornton-Trump, G.W.Brodland (Dept. of Mech. Engng., Univ. of Manitoba, Winnipeg, Manitoba, Canada).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.293-301 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Traditional locomotion analysis considers motion in a translating coordinate frame and the analysis is performed primarily in the sagittal plane. The results of several studies by the authors described here, have shown that the aspect of symmetry is rarely present in pathological gait. The work described illustrates the use of biplane photography for displacement measurement in human movement. Transformations based on Eulerian angle rotations are derived based on biplane measurements. From the three dimensional ground reaction forces measured by a force plate, moments about the moving upper body coordinate axes are computed through a three dimensional mathematical model. (12 refs.)

110070 Variations in gait patterns of runners: relationship to anthropometric measurements. S.Adelsberg, C.Tauber, J.Au, J.Pugh (Dept. of Orthopaedics, Hospital for Joint Diseases Orthopaedic Inst., New York, NY, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.302-6 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
High-speed computerized motion analysis was used to assess the running parameters of a group of runners. Anthropometric measurements were taken on the group of runners in an effort to provide possible correlations between running style, speed, and anthropometry. The most consistent correlation was between speed and stride length. Femur length and stride length was only highly correlated for the runners at the fastest speeds. The faster runners also had a gait pattern characterized by significantly lower ground contact time than that of the slower runners. Of prime importance in running is behaviour of the body during float phase, and mediated by anthropometry and the biomechanical characteristics of the stance phase. (2 refs.)

110071 Orthopaedic application of spatio temporal analysis of body form and function. C.Tauber, J.Au, S.Bernstein, A.Grant, J.Pugh (Dept. of Orthopaedics, Hospital for Joint Diseases Orthopaedic Inst., New York, NY, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.307-13 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Spatial and temporal analysis of walking provides the orthopaedist with objective evidence of functional ability and improvement in a patient. Patients with orthopaedic problems experiencing extreme pain and, consequently, irregularities in joint motions on weightbearing are videorecorded before, during and after a course of rehabilitative treatment and/or surgical correction of their disability. A specially-programmed computer analyzes these tapes for the parameters of walking by locating reflective spots which indicate the centers of the lower limb joints. The following parameters of gait are then generated: dynamic hip, knee and foot angles at various intervals during walking; vertical, horizontal and lateral displacements of each joint at various time intervals; linear and angular velocities of each joint; and the relationships between the joints during various phases of the gait cycle. (2 refs.)

110072 A large deformation analysis for aortic walls under a physiological loading. J.C.Misra, S.I.Singh (Dept. of Math., Indian Inst. of Technol., Kharagpur, India).
Int. J. Eng. Sci. (GB), vol.21, no.10, p.1193-202 (1983).
An analytical study for the large deformation of aortic walls, based on the theory of nonlinear viscoelasticity, treating the wall tissue as orthotropic and incompressible, is presented. The aorta is considered as a long and thick-walled cylindrical vessel. The effect of the surrounding tissues which are assumed to be isotropic and incompressible, is incorporated in the analysis. Also the effects of the inertial force for the motion of the wall and the longitudinal extension experienced by blood vessels under a physiological loading, are accounted for. By using additive forms of the stress relaxation functions characterizing the viscoelastic behaviour of wall tissues, the applicability of the mathematical analysis is illustrated through numerical computation of the strain- and stress-fields in the walls of middle descending thoracic aorta. (22 refs.)

110073 Apparant depression of right ventricular function after selective reduction of left ventricular inotropy: an interpretation of experimental data utilising a computer-based circulatory model. H.Piene, O.A.Smiseth (Dept. of Physiology, Univ. of Tromso, Tromso, Norway), H.Refsum, J.V.Tyberg.
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.548-56 (Sept. 1983).
Consequences of ventricular interations upon commonly used descriptions of ventricular diastolic and systolic properties were inferred from a circulatory model. The model included active heart compartments, vascular interconnections and the pericardium and was adapted on a digital computer. Numerical values assigned to model parameters were such as to resemble the circulatory system of the dog. Model predictions were utilised to analyse experimental observations in a dog preparation with closed chest and pericardium. Dog ventricular and pericardial pressures (P) and volumes (V) were measured in a control situation and after ischaemic depression of left ventricular function. Model predictions and experiment observations were qualitatively identical. The findings imply that the diastolic P-V relationship of one heart compartment cannot be assessed by measurements in this compartment alone, and that function curves of one ventricle are affected by ventricular interactions which cannot be separated from true alterations in the inotropic state. (11 refs.)

110074 The role of calcium in the mechanical behaviour of bone. R.J.Minns (Regional Medical Phys. Dept., Dryburn Hospital, Durham, England), A.Atkinson, F.S.Steven.
Phys. Med. & Biol. (GB), vol.28, no.9, p.1057-66 (Sept. 1983).
Plugs of fresh post mortem human patellar subchondral bone were soaked for three weeks in an organic solvent (ethanol) which contained a chelating agent (EDTA). This technique selectively removes the calcified inorganic component without disrupting the structure of the remaining bone matrix. These plugs, together with untreated plugs as controls, were treated in unconfined compression at a fixed strain rate and allowed to relax to evaluate the contribution made by the calcium component to the physical and time-dependent properties of subchondral bone. (27 refs.)

110075 Computerized model of coronary-pulmonary circulation. L.R.Low, J.P.Windham (Dept. of Radiology, Medical Coll. of Ohio, Toledo, OH, USA).
23rd Midwest Symposium on Circuits and Systems, Toledo, OH, USA, 4-5 Aug. 1980 (North Hollywood, CA, USA: Western Periodicals 1980), p.547-51
A mathematical model of the human cardio-pulmonary circulation has been developed. A method has been devised of optimally matching this model to simulated data generated by a model program, in the presence of simulated

noise and an arbitrary, (known), input function. A sensitivity analysis has given a qualitative measure of the relative reliability of the estimates of the heart transfer constants. The technique has been applied to clinical data obtained from a cardiac first pass radionuclide study. (6 refs.)

87.50 BIOLOGICAL EFFECTS OF RADIATIONS

(inc. effects of fields)

110076 Short- and long-term effects of whole-body irradiation with fission neutrons or X-rays on the thymus in CBA mice. R.Huiskamp, J.A.G.Davids (Netherlands Energy Res. Found. ECN, Petten, Netherlands), O.Vos.
Radiat. Res. (USA), vol.95, no.2, p.370-81 (Aug. 1983).
Young adult (6 weeks old) female CBA mice were exposed to whole-body irradiation with either 2.5-Gy fast fission neutrons of 1 MeV mean energy or 6.0-Gy 300 kVp X-rays at center-line dose rates of 0.1 and 0.3 Gy/min, respectively. The weight of spleen and animal and the weight, cellularity, and histological structure of the thymus were studied at different times after irradiation. Thymic recovery after whole-body irradiation showed a biphasic pattern with minima at 5 and 21 days after irradiation and peaks of regeneration at days 14 and 42 after X-irradiation or at days 14 and 70 after neutron irradiation. After the second phase or recovery, a marked decrease in relative thymus weight and cellularity was observed, which lasted up to at least 250 days after irradiation. Splenic recovery showed a monophasic pattern with an overshoot on day 21 after irradiation. After neutron irradiation a late decrease in relative spleen and animal weight was observed. The observed late effects on thymus and spleen weight and thymus cellularity are discussed in terms of a persistent defect in the bone marrow. (33 refs.)

87.50B Interactions of biosystems with radiations

110077 Energy adsorption from waveguides in biological-like media. M.Bozzetti (Dipartimento di Elettrotecnica ed Elettronica, Univ. di Bari, Bari, Italy), R.de Leo, C.Ercoli.
Alta Freq. (Italy), vol.52, no.3, p.185-7 (May-June 1983). (4th Italian National Meeting on Applied Electromagnetics, Florence, Italy, 4-6 Oct. 1982).
The EM radiation of open-ended waveguides into a biological medium is analyzed in order to obtain the dissipated power distribution into the biological body along with the aperture radiation characteristics as a function of waveguide excitation and of biological medium parameters. (3 refs.)

110078 Dielectric properties of ocular tissues at 374°C. C.Gabriel, R.J.Sheppard, E.H.Grant (Phys. Dept., Queen Elizabeth Coll., London, England).
Phys. Med. & Biol. (GB), vol.28, no.1, p.43-9 (Jan. 1983). [received: Sept. 1983]
Values of the relative permittivity, dielectric loss and conductivity are given for various rabbit ocular tissues at frequencies in the range 10 MHz-10 GHz. The tissues measured were cornea, retina, choroid, iris, and the cortical and nuclear zones of the lens. The dielectric parameters were determined using the technique of multiple response time domain spectroscopy. For all tissues the water relaxation could be characterised by a Debye dispersion with a relaxation time longer than that of pure water, indicating that its dielectric behaviour was affected by the presence of the biological macromolecules. (16 refs.)

87.50E Bio-optics (effects of microwaves, light, laser and other electromagnetic waves)

110079 Microwave effects on cell cultures. G.d'Ambrosio, G.Ferrara, A.Scaglione (Istituto Elettrotecnico, Univ. di Napoli, Napoli, Italy), G.Colletta, P.P.di Fiore.
Alta Freq. (Italy), vol.52, no.3, p.179-81 (May-June 1983). (4th Italian National Meeting on Applied Electromagnetics, Florence, Italy, 4-6 Oct. 1982).
F4/6 Friend cells were chosen as a suitable system for investigating microwave induced bioeffects. A number of preliminary tests were carried out regarding the response of the cultures to conventional heating and to other stresses. Serum-free samples were exposed to pulsed wave or to continuous wave, or were conventionally heated. Comparison of growth rates showed an inhibitory effect due to pulsed radiation. (12 refs.)

110080 Analysis of the safety levels for impulsive electromagnetic fields. P.Bernardi, G.D'Inzeo (Dipartimento di Elettronica, Univ. Degli Studi di Roma, Roma).
Alta Freq. (Italy), vol.52, no.3, p.182-4 (May-June 1983). (4th Italian National Meeting on Applied Electromagnetics, Florence, Italy, 4-6 Oct. 1982).
The quantitative criteria for setting the safety levels of nonionizing electromagnetic waves are usually based on interaction mechanisms that produce thermal effects and do not refer to other possible mechanisms. The authors examine the effects that an electromagnetic field incident on a biological tissue produces at the cell membrane level, inducing on the membrane a voltage that alters its resting conditions. In particular, for impulsive fields, they have evaluated if the usual standard levels are of actual security in the light of this mechanism of interaction. (6 refs.)

110081 Heat flow in laser-irradiated biological systems: some experimental considerations. G.Delfino, E.Casale (Inst. di Cibernetica, CNR, Napoli, Italy).
Appl. Opt. (USA), vol.22, no.17, p.2712-15 (1983).
The investigation of problems of heat transmission in laser-irradiated samples and the relative modelistic approaches acquire particular significance when whole biological specimens are considered. The possibility of employing a theoretical model, generally utilized in laser irradiation of solid materials, is here analyzed in the irradiation of biological samples. Also, experimental modifications of the thermal diffusivity values are related to the energy level of the single optical pulse obtained from a CW Ar^+ laser. (11 refs.)

110082 Stimulation of E. coli growth by laser and incoherent red light. T.J.Karu, O.A.Tiphlova (Laser Tech. Center, Acad. of Sci., Troitzk, USSR), V.S.Letokhov, V.V.Lobko.
Nuovo Cimento D (Italy), vol.2D, ser.1, no.4, p.1138-44 (July-Aug. 1983).
The effect of low-intensity He-Ne laser radiation ($\lambda=632.8$ nm) and incoherent red light on DNA synthesis and cell division in Escherichia coli has been studied. It has been shown that the radiations of He-Ne laser ($\lambda=632.8$ nm) and filament lamp ($\lambda=(631\pm4)$ nm) stimulate DNA synthesis and cell growth at doses of 10^3 to 10^4 J/m^2. The highest level of DNA synthesis is observed 10 min after irradiation and the difference in the numbers of irradiated and control cells is maximum 1 or 2 h after irradiation. The action spectrum of visible light on the growth rate of E. coli cells (from 560 nm to 640 nm) has been measured. The action spectrum has its maximum at (620 ± 7) nm. (7 refs.)

110083 Observations of Syrian hamster features after exposure to 2450-MHz microwaves. E.Berman, H.B.Carter (Experimental Biology Div., Health Effects Res. Lab., Research Triangle Park, NC, USA), D.House.
J. Microwave Power (Canada), vol.17, no.2, p.107-12 (June 1982).
The teratogenic potential of microwaves was examined in a rodent species, the Syrian hamster. Exposure of hamsters to 2450-MHz CW microwaves at a power density of 20 mW/cm^2 (estimated SAR=6 mW/g) for 100 minutes daily on days 6-14 of gestation caused no significant change in fetal survival, body weight, skeletal maturity, or incidence of terata. Thirty mW/cm^2 (estimated SAR=9 mW/g) caused significantly increased fetal resorptions, decreased fetal body weight, and decreased skeletal maturity. Rectal temperatures of pregnant hamsters after exposure to 20 mW/cm^2 were slightly increased (0.4°C) over those of sham-irradiated dams; 30 mW/cm^2 caused maternal rectal temperatures to be increased 1.6°C over sham-irradiated dams' temperatures. It appears that the hamster fetus may be more susceptible to microwave radiation than the mouse. (11 refs.)

110084 Assessment of immune function development in mice irradiated in utero with 2450-MHz microwaves. R.J.Smialowicz, M.M.Riddle, R.R.Rogers, G.A.Stott (Health Effects Res. Lab., US Environmental Protection Agency, Research Triangle Park, NC, USA).
J. Microwave Power (Canada), vol.17, no.2, p.121-6 (June 1982).
Groups of time-bred pregnant mice were irradiated with 2450-MHz microwaves at an incident power density of 28 mW/cm^2 for 100 min daily from day 6 to day 18 of pregnancy. The average specific absorption rate (SAR) was 16.5 W/kg. Two experiments were performed under these conditions. At 3 and 6 weeks of age the mice were assessed for development of the primary immune response to sheep erythrocytes, in vitro mitogen stimulated lymphocyte proliferation, and natural killer (NK) cell activity. No consistent significant difference in the primary immune response, in the mitogen response, or in the NK cell activity was observed between irradiated and sham-irradiated mice. (17 refs.)

110085 Effects of ambient temperature and exposure to 2450-MHz microwave radiation on evaporative heat loss in the mouse. C.J.Gordon (Health Effects Res. Lab., US Environmental Protection Agency, Research Triangle Park, NC, USA).
J. Microwave Power (Canada), vol.17, no.2, p.145-50 (June 1982).
Whole-body evaporative heat loss was measured as whole-body evaporative water loss in mice during a 90-min exposure to 2450-MHz microwave radiation at an ambient temperature of 20°C and in non-exposed mice maintained at ambient temperatures of 20, 25, 30, 33, and 35°C. The ambient-temperature threshold for increasing evaporative water loss was between 30

and 33°C. A specific absorption rate of microwave radiation in excess of 29 W/kg was required to produce an increase in heat loss. For absorption rates ranging from 29 to 44 W/kg, the mouse dissipated 65% of the total absorbed heat by water evaporation; the remainder was dissipated passively. The data collected in the mouse may be extrapolated to larger species, such as man, but only by an exponential relationship. Using this relationship, it was shown that a threshold specific absorption rate of 29 W/kg in a 0.033-kg mouse was equivalent to approximately 0.25 W/kg in a 70-kg human. (25 refs.)

110086 Comments on a review of radiofrequency and microwaves (EHC 16) by Sol M. Michaelson (Radiat. Res. 92, 217-219 (1982)) [and reply]. M.L.Shore (Nat. Center for Devices & Radiological Health, Food & Drug Administration, Dept. of Health & Human Services, Rockville, MD, USA), M.H.Repacholi, B.Servantie, P.Czerski, S.M.Michaelson.
Radiat. Res. (USA), vol.95, no.2, p.414-20 (Aug. 1983).
As members of the WHO working group, which developed the international consensus for and the text of the environmental health criteria #16 of the World Health Organization, Radiofrequency and Microwaves (EHC 16), Shore et al. respond to the review of the document prepared by Dr. Sol M. Michaelson. They have a somewhat different perspective on the criteria document EHC 16 than that which Dr. Michaelson provided. Dr. Michaelson's main thesis is that EHC 16 is 'unbalanced', in that literature that supports so-called nonthermal interactions was included in the report 'wiith cursory critique and quite often at the expense of literature which refutes such viewpoints', and so EHC 16, in his opinion, 'does not come up to the high scientific caliber and accuracy of the usual WHO publications'. Various points of Dr. Michaelson's review are commented on and in a reply Dr. Michaelson comments on the comments. (no refs.)

87.50G Ionizing radiations (u.v., X-ray, gamma-ray; particle radiation effects)

110087 Response of a human colon adenocarcinoma (DLD-1) to X-irradiation and mitomycin C in vivo. E.N.Spremulli (Dept. of Medicine, Roger Williams General Hospital, Providence, RI, USA), J.T.Leith, S.F.Bliven, D.E.Campbell, D.L.Dexter, A.S.Glicksman, P.Calabresi.
Int. J. Radiat. Oncology Biol. Phys. (GB), vol.9, no.8, p.1209-12 (Aug. 1983).
Mice hosting a heterogeneous human colon xenograft tumor produced by subcutaneous injection of the DLD-1 tumor cell line were treated either with X-irradiation alone, with mitomycin C alone (4 mg/kg), or with X-irradiation given two hours after intraperitoneal injection of mitomycin C (4 mg/kg). Radiation alone produced a dose dependent delay in the time needed for tumors to regrow to twice their size at the time of irradiation, and in the mice receiving mitomycin C plus X-irradiation, an additional growth delay equivalent to that produced by 3-3.5 Gy of X-rays was seen at all X-ray dose level. As the DLD-1 tumor xenografts do not appear to possess a significant hypoxic fraction, the authors conclude that the two agents are acting in a simple additive cytotoxic manner by the killing of oxic tumor cells. (16 refs.)

110088 Recombination of parent and daughter strand DNA after UV-irradiation in mammalian cells. A.J.Fornace,Jr. (Lab. of Pathology, NIH, Bethesda, MD, USA).
Nature (GB), vol.304, no.5926, p.552-4 (11 Aug. 1983).
The mechanism by which mammalian cells replicate DNA containing pyrimidine dimers is poorly understood. When DNA synthesis is initiated after UV-irradiation in bacteria, parental DNA containing pyrimidine dimers has been shown to 'exchange' into the daughter strand DNA by a recA-dependent mechanism. The author reports that up to 3 dimers per 10^9 daltons of daughter strand DNA could be detected 34-45 h after UV-irradiation in human peripheral blood lymphocytes, normal human fibroblasts, group A xeroderma pigmentosum fibroblasts and mouse 3T3 cells. This represents approximately 1-3% of the dimers present in the parent strand at this time after UV. (23 refs.)

110089 Targeted mutagenesis of SV40 DNA induced by UV light. F.Bourre, A.Sarasin (Inst. de Recherches Sci. sur le Cancer, Villejuif, France).
Nature (GB), vol.305, no.5929, p.68-70 (1 Sept. 1983).
UV light is a potent mutagen in most living cells, but molecular analysis of its mode of action in animal cells has not been possible because of the high complexity of the cell genome. Therefore, the authors have used simian virus 40 (SV40) as a biological probe to study the mutagenic effect of UV-irradiation at the molecular level. A thermosensitive SV40 mutant of the large T antigen (tsA58), which is defective at high temperature for intitiation of viral DNA replication and for repression of early transcription, was UV-irradiated in vitro, then replicated in monkey kidney cells. Revertants of tsA58 were selected for growth at the nonpermissive temperature, then the reversion sites were mapped by using the marker rescue technique, and precisely localized by DNA sequencing. The authors report that all revertants analysed showed one or two base pair substitutions localized in the C-terminal half of the T antigen gene. The original tsA mutation was still present in all revertent genomes. In 16 DNAs sequenced, seven reversion sites were found on the large T antigen gene, all of which localized opposite a possible UV-induced pyrimidine-pyrimidine lesion, suggesting targeted mutagenesis. UV-irradiation of the host cell before infection did not change the pattern of reversion sites at the molecular level, although it strongly increased the mutation frequency. These results demonstrate for the first time in animal cells the specificity of UV-induced mutagenesis. (20 refs.)

110090 Bremsstrahlung production by potassium-40 in muscle. S.G.Graham (Atomic Weapons Research Establ., Reading, England).
Phys. Med. & Biol. (GB), vol.28, no.1, p.19-30 (Jan. 1983). [received: Sept. 1983]
The bremsstrahlung spectrum produced when 1320 keV beta particles, emitted by the naturally occurring isotope ^{40}K, are absorbed in muscle has been calculated. With reference to the external measurement of ^{239}Pu in the lung using the 17 keV UL X-rays, a simple model was used to estimate the number of bremsstrahlung photons with energies between 12 and 25 keV that would emerge from the chest wall of a normal subject. This was calculated to be 3 min^{-1} for a detection area of 628 cm^2, although internal bremsstrahlung may increase this to 4 in^{-1}. The latter figure is a factor of approximately three lower than the counting rate observed when a pair of phoswich NaI detectors of the same total area are placed over an average subject. Possible reasons for this discrepancy are discussed. (27 refs.)

110091 The applications of track calculations to radiobiology. I. Monte Carlo simulation of proton tracks. M.Zaider (Coll. of Physicians & Surgeons, Columbia Univ., New York, NY, USA), D.J.Brenner, W.E.Wilson.
Radiat. Res. (USA), vol.95, no.2, p.231-47 (Aug. 1983).
In the first of a series of papers on the application of track-structure calculations to radiobiology, a detailed Monte Carlo proton transport code in water vapor is described. In the code all important interaction types (elastic scattering, five levels of ionization, 12 types of excitation) are considered explicitly. All cross sections are based closely on experimental data. The proton energy range considered is 0.3-1.5 MeV since this is the range of available experimental ionization cross sections. Results are presented in terms of energy partitions, w values, stopping powers, and radial dose distributions, all showing agreement with the experiment. (49 refs.)

110092 Resistance of human erythrocytes containing elevated levels of vitamin E to radiation-induced hemolysis. M.A.Brown (School of Biological Sci., Macquarie Univ., North Ryde, Australia).
Radiat. Res. (USA), vol.95, no.2, p.303-16 (Aug. 1983).
Human erythrocytes were isolated from the blood of healthy donors and then incubated in the presence of suspensions of α-tocopherol for 30 min at 37°C. Unabsorbed tocopherol was removed by centrifugation using several washes of isotonic phosphate-buffered saline. Washed erythrocytes were resuspended to 0.05% Hct and exposed to hemolyzing doses of ^{60}Co gamma radiation, and hemolysis was monitored continuously by light scattering at 700 nm in a recording spectrophotometer. The extent of hemolysis with time was sigmoid and data analysis was carried out on the time taken for 50% hemolysis to occur ($t_{50\%}$). The vitamin E content of erythrocytes was significantly elevated by the incubation procedure and resulted in the cells exhibiting a significantly increased resistance to hemolysis as reflected by the extended $t_{50\%}$ values. Oral supplementation of 500 IU of vitamin E per day to eight normal human subjects for a period of 16 days also resulted in their washed erythrocytes exhibiting a significant increase in resistance of radiation-induced hemolysis. When comparing vitamin E incubated cells with control cells, both the dose-reducing factor and the time for 50% hemolysis quotient ($Qt_{50\%}$) were observed to increase with increasing radiation dose. (30 refs.)

110093 DNA damage in irradiated endothelial cells of the rat cerebral cortex. Protective action of cysteamine in vivo. H.Cerda, K.Rosander (Dept. of Phys. Biology, Gustaf Werner Inst., Uppsala, Sweden).
Radiat. Res. (USA), vol.95, no.2, p.317-26 (Aug. 1983).
The induction and repair of DNA damage by ^{60}Co in single endothelial cells of rate cerebral cortex capillaries were studied in vivo and in vitro. Capillaries from the cerebral cortex were prepared in suspension, embedded in agarose on microscope slides, and treated with alkaline solution (causes unwinding of DNA). After neutralization the slides were stained with the fluorescent dye acridine orange and endothelial cell nuclei were evaluated in a microscope photometer. The intensity of the red fluorescence (from single-stranded DNA) divided by the green fluorescence (from double-stranded DNA) was used as a measured of DNA strand breaks. The results showed that most DNA strand breaks were repaired within 30 min postirradiation. A linear dose-effect relationship was found up to 18 Gy. Similar results were obtained from in vitro and in vivo experiments. Cysteamine administered 20 min before irradiation in vivo gave a protective effect on the cells studied. An EMF of 1.3 was determined. (28 refs.)

110094 Hyperthermic potentiation of unrejoined DNA strand breaks following irradiation. M.D.Mills, R.E.Meyn (Dept. of Phys., Univ. of Texas, Houston, TX, USA).
Radiat. Res. (USA), vol.95, no.2, p.327-38 (Aug. 1983).
Previous reports have suggested that the potentiation of cellular radiation sensitivity by hyperthermia may be due to its inhibition of the repair of single-strand breaks in DNA. Such inhibition could result in increased numbers of unrejoined breaks at long times following irradiation, lesions that are presumed to be lethal to the cell. As a test of this hypothesis, the amounts of residual strand-break damage in cells following combined hyperthermia and ionizing radiation (^{137}Cs γ-rays) were measured. The results show that hyperthermia does significantly enhance the relative number of unrejoined strand breaks as measured by the technique of alkaline elution and that the degree of enhancement is dependent on both the temperature and duration of the hyperthermia treatment. For example, compared to unheated cells, the proportion of unrejoined breaks measured 8 hr after irradiation was increased by a factor of 1.5 in cells that were treated for 30 min at 43°C, by a factor of 6 for cells treated for 30 min at 45°C, and by a factor of 4 for cells treated at 43°C for 2 hr. In experiments in which the sequence of heat and irradiation were varied, a high degree of correlation was observed between the resulting level of cell killing and the relative numbers of unrejoined strand breaks. The greatest effects of both of these parameters were observed in those protocols in which the irradiation was delivered either during, just before, or just after the heat treatment. (28 refs.)

110095 A comparison of the lethal effects of intracellular radionuclides in human and rodent cells. P.K.LeMotte, J.B.Little (Dept. of Physiology, Harvard School of Public Health, Boston, MA, USA).
Radiat. Res. (USA), vol.95, no.2, p.359-69 (Aug. 1983).
The relative sensitivities of a human diploid fibroblast strain (AG1522) and an established line of contact-inhibited mouse embryo fibroblasts (10T1/2) were compared after incorporation of [^{3}H]thymidine or [^{125}I]-iododeoxyuridine into the cellular DNA and growth at 37°C. Whereas these cells show similar sensitivities to acute X-irradiation, the D_0 for clonal survival of the mouse fibroblasts was 5- to 10-fold higher than the D_0 for the human fibroblasts for both ^{3}H and ^{125}I. A large difference in sensitivity between these two cell types was also seen after protracted irradiation form ^3H_2O at 37°C, but this difference was markedly reduced when cells were exposed to ^3H_2O at 0°C to simulate an 'acute' irradiation. An established human tumor cell line was similarly hypersensitive to killing by ^3H_2O at 37°C as compared with early passage diploid hamster embryo cells. These results indicate that human cells are more radiosensitive than rodent cells when a radiation dose is protracted over several days rather than given as an 'acute' exposure, and are consistent with the hypothesis that human cells are hypersensitive to low-dose-rate irradiation as compared with rodent cells. (14 refs.)

110096 The repair of sublethal damage in diploid human fibroblasts: a comparison between human and rodent cell lines. M.L.Freeman, E.Sierra, E.J.Hall (Dept. of Radiology, Columbia Univ., New York, NY, USA).
Radiat. Res. (USA), vol.95, no.2, p.382-91 (Aug. 1983).
Two diploid cell lines of human origin were irradiated in vitro. Repair of sublethal damage was observed in both lines when they were exposed to a single γ-ray dose and incubated at 37°C prior to receiving a graded second dose. In addition cells were irradiated at a low dose rate (56 or 76 rad/hr) and survival was compared to that after an acute exposure. A dose-rate effect was demonstrated. Sublethal damage repair was also studied using CHO or V-79 Chinese hamster cells, and the data suggest that the degree of repair is similar in human and rodent cell lines at photon doses up to 500 rad. The

repair of sublethal damage can be a significant factor in the survival of human cells in vitro for fractionated doses. (12 refs.)

110097 Quantitative radiation dose-response relationship for normal tissues in man. II. Response of the salivary glands during radiotherapy. K.L.Mossman (Dept. of Radiation Medicine, Georgetown Univ. Medical Center, Washington, DC, USA).
Radiat. Res. (USA), vol.95, no.2, p.392-8 (Aug. 1983).
For pt.I see ibid., vol.91, p.265-74, 1982. A quantitative dose-response curve for salivary gland function in patients during radiotherapy is presented. Salivary-function data used in this study was obtained from four previously published reports. All patients were treated with ^{60}Co teletherapy, to the head and neck using conventional treatment techniques. Salivary dysfunction was determined as specific dose levels by comparing salivary flow rates before therapy with flow rates at specific dose intervals during radiotherapy up to a total dose of 6000 cGy. Fifty percent salivary dysfunction occurred after 1000 cGy and eighty percent dysfunction was observed by the end of the therapy course (6000 cGy). The salivary-function curve was also compared to the previously published dose-response curve for taste function (pt.I). Comparisons of two curves indicate that salivary dysfunction precedes taste loss and that the shapes of the dose-response curves are different. A new term, tissue tolerance ratio, defined as the ratio of responses of two tissues given the same radiation dose, was used to make the comparisons between gustatory and salivary gland tissue effects. Measurements of salivary gland function and analysis of dose-response curves may be useful in evaluating chemical modifiers of radiation response. (17 refs.)

110098 Are lesions induced by ionizing radiation direct blocks to DNA chain elongation?. R.B.Painter (Lab. of Radiobiology & Environmental Health, Univ. of California, San Francisco, CA, USA).
Radiat. Res. (USA), vol.95, no.2, p.421-6 (Aug. 1983).
Ionizing radiation blocks DNA chain elongation in normal diploid fibroblasts but not in fibroblasts from patients with ataxia-telangiectasia, even though there are no differences in the damage induced between the two cell types. This difference suggests that radiation-induced lesions in DNA are not themselves blocks to chain elongation in ataxia cells and raises the possibility that in normal cells a mediator exists between DNA damage and chain termination. (17 refs.)

110099 Experimental condition and the acute reaction of mouse skin to ionizing radiation. H.D.Suit, G.Silver, R.S.Sedlacek (Dept. of Radiation Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA), A.Walker.
Radiat. Res. (USA), vol.95, no.2, p.427-33 (Aug. 1983).
The acute reactions of skin of the thigh-leg of normal young adult C3Hf/Sed mice following five equal radiation doses (^{60}Co) were studied in mice irradiated at various leg skin temperatures and while respiring various gas mixtures in control or anesthetized condition (sodium pentobarbital, 0.05 mg/g^{-1} body wt.). At 25 and 35°C, anesthesia reduced the RD_{50} (2.5+reaction) by 4-5%. An increase of temperature from 25 to 35°C resulted in a decrease in RD_{50} by 10-12% for subjects respiring air or 5% for subjects respiring O_2 at 1 or at 3 ATA. The major modifier of radiation response was to change from respiration of air to O_2 at 1 or 3 ATA. Enhancement ratios for RD_{50} Air/O_2 1 ATA were 1.4-1.5 for 25 and 35°C. The ratios O_2 1 ATA/3 ATA were 1-1.05. (21 refs.)

87.60 MEDICAL AND BIOMEDICAL USES OF FIELDS, RADIATIONS, AND RADIOACTIVITY

(see also 28.80 Nuclear radiation technology, including shielding)

110100 Engineering research in medical imaging: a synergistic relationship. M.M.Ter-Pogossian (Mallinckrodt Inst. of Radiology, Washington Univ. School of Medicine, St. Louis, MO, USA).
IEEE Trans. Med. Imaging (USA), vol.MI-1, no.4, p.206-9 (Dec. 1982). [received: Sept. 1983]
Discusses some of the very basic aspects of medical imaging including computed tomography, digital radiography, emission tomography, ultrasound, and nuclear magnetic resonance. (no refs.)

110101 Overview of a unified SNR analysis of medical imaging systems. R.F.Wagner, D.G.Brown (Office of Radiological Health, Food and Drug Administration, Rockville, MD, USA).
IEEE Trans. Med. Imaging (USA), vol.MI-1, no.4, p.210-12 (Dec. 1982). [received: Sept. 1983]
In their studies of medical imaging systems over the last decade the authors find that there are elements common to all systems which, when properly understood, simplify the analysis and understanding of these systems and their performance. They present a brief introductory overview of these elements. (20 refs.)

87.60B Sonic and ultrasonic radiation

110102 Medical ultrasound: is there a hazard. M.H.Repacholi (Non-Ionizing Radiation Section, Health & Welfare Canada, Ottawa, Ontario, Canada).
Australas. Phys. & Eng. Sci. Med. (Australia), vol.6, no.2, p.64-70 (April-June 1983). [received: Aug. 1983]
With the very large numbers of people exposed to ultrasound, it is normal to pose the question—is there any hazard to health?. The author concludes that, with the precautions and recommendations noted, the actual or potential risks of human exposure to medical ultrasound would be minimal. At this stage in one's knowledge, any detriments from ultrasound exposure are insignificant compared to the benefits. (41 refs.)

110103 Spectral energy of the first heart sound in relation to mitral valve size parameter. T.C.Hearn (Dept. of Appl. Maths., Univ. of Adelaide, Adelaide, Australia), J.Mazumdar, E.Goldblatt, D.Nandagopal, N.L.Fazzalari.
Australas. Phys. & Eng. Sci. Med. (Australia), vol.6, no.2, p.76-81 (April-June 1983). [received: Aug. 1983]
Simultaneous phonocardiograms and two dimensional echocardiograms were recorded from twelve children subjects. Stop-action frames of the mitral valve in parasternal long-axis and four-chambered views were photographed from the video-taped echocardiographic recordings, to provide biaxial measurements of the mitral valve diameter for each subject. The product of the two diameter measurements was used as a size parameter for the mitral valve. From the corresponding digitized phonocardiograms, first heart-sound power spectra were obtained by means of fast Fourier transformation. The relative area of the spectra in 15 Hz intervals up to 150 Hz was then correlated with the mitral valve size parameter. It was noted that the best correlation was attained in the 30-45 Hz bandwidth. A possible interpretation in terms of documented heart-sound determinants is discussed. (7 refs.)

110104 Semireal time monitoring of the functional movements of the mandible. R.J.Isaacson (Dept. of Growth & Dev., Univ. of California, San Francisco, CA, USA), S.Baumrind, S.Curry, R.A.Molthen.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.22-35 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Many branches of dental practice would benefit from the availability of a relatively accurate, precise, and efficient method for monitoring the movements of the human mandible during function. The authors report work aimed at developing a relatively non-restrictive semireal time acoustical system for monitoring the functional movement of the mandible relative to the rest of the head. A set of three sparking devices is mounted to the mandibular component of a light, relatively non-constraining extra-oral harness and another set of three sparkers is attached to the harness's cranial or skull component. The sparkers are fired sequentially by a multiplexer and the sound associated with each firing is recorded by an array of three or more microphones. Computations based on the known speed of sound are used to evaluate the distances between the sparkers and the microphones. These data can then be transformed by computer to provide numeric or graphic information on the movement of selected mandibular landmarks with respect to the skull. Total elapsed time between the firing of the sparkers and the display of graphic information need not exceed 30-60 seconds using even a relatively modest modern computer. (22 refs.)

110105 Transverse forces on a finger tendon analyzed using transmission ultrasound imaging. P.Dev, K.W.Marich, V.R.Hentz (Rehabilitative Engng. Res. & Dev. Center, Veterans Adminstration, Palo Alto, CA, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.262-6 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Transmission ultrasound imaging (TUS) with the SRI camera has been used to visualize the index finger flexor tendons in live hands during flexion-extension movements. The digitised data on tendon trajectory is analysed to obtain tendon curvature. Assuming the tendon to be frictionless, the relative transverse forces on the tendon are computed. The distribution of these forces along the tendon, and the changes in this distribution, indicate how tendon force may be transmitted to the bone to cause movement. (2 refs.)

110106 Imaging modalities [medical]. A.Moss (Dept. of Radiology, Univ. of California, San Francisco, CA, USA).
IEEE Trans. Med. Imaging (USA), vol.MI-1, no.4, p.215-19 (Dec. 1982). [received: Sept. 1983]
A review of ultrasound, X-ray computed tomography and NMR is given. Ultrasound has the advantages of portability, harmlessness and real-time data acquisition. NMR also is probably harmless. Computed tomography has the best spatial resolution while the main advantage of NMR scanning is improved contrast discrimination between tissues. The particular organs/systems that these techniques are best for are discussed. (no refs.)

110107 Medical diagnosis by ultrasound. A.Trono.
Elettrotecnica (Italy), vol.70, no.4, p.315-20 (April 1983). In Italian.
Describes the principles of ultrasound generation and the mechanism of its propagation through human tissue. Outlines the basis of ultrasound assisted diagnosis with some illustrated examples. (no refs.) *M.P.R.*

110108 In vivo measurement of thickness or of speed of sound in biological tissue structures. H.Ohkawai, S.-I.Nitta, M.Tanaka (Res. Inst. for Chest Diseases & Cancer, Tohoku Univ., Sendai, Japan), F.Dunn.
IEEE Trans. Sonics & Ultrason. (USA), vol.SU-30, no.4, p.231-7 (July 1983).
Though the wave reflected from thin biological tissue structures is affected by interference, the wave transmitted through thin tissue is not. This implies the possibility of in vivo measurement of thickness or of sound speed in thin tissue structures. Spectroscopy facilitates the measurement. Measurement of these quantities are presented for plastic plates, and for in vivo thickness measurement of the mitral valve and in vivo measurement of the aortic and tricuspid valves of dog hearts. The values obtained for the thickness of the valves from in vivo and from in vitro acoustic measurements by this method and from micrometer measurement of the excised tissues compare favorably. (9 refs.)

110109 Experiments in automatic classification of laryngeal pathology. M.Mezzalama, P.Prinetto, B.Morra (Istituto di Elettrotecnica Generale, Politecnico di Torino, Torino, Italy).
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.603-11 (Sept. 1983).
Addresses the problems of the automatic classification of laryngeal pathology using a quantitative measure of voice-extracted parameters. Preliminary results show that a proper selection of these parameters guarantees a satisfactory discrimination capability. The selected features for classification purposes are discussed and a model of the speech production system in the case of laryngeal pathologies is presented. (16 refs.)

110110 Automated apnoea detection by computer: analysis of tracheal breath sounds. J.Peirick, J.W.Shepard,Jr. (Geriatric Res., Education & Clinical Centre, St. Louis VA Medical Centre, St. Louis, MO, USA).
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.632-5 (Sept. 1983).
Complete polygraphic evaluation of sleep involves considerable equipment, expense, and personnel time for the collection and analysis of the data. An automated method of reliably evaluating patients for sleep apnoea using a minimum of apnoea detection equipment and personnel time would be clinically useful. Such a method has been devised, using tracheal sound as the physiological indicator of apnoea. Tracheal sound is monitored by a microcomputer, which detects periods of low tracheal sound corresponding to a lack of airflow. Periods of low tracheal sound which last 10s or longer are recorded overnight and stored for review by the user at any time. This tracheal sound method of apnoea detection has been compared with data obtained during polygraphic sleep studies utilising thermistors to detect airflow and an ear oximeter to monitor arterial oxygen saturation. The results compare favorably, and although tracheal sound detection introduces some error into apnoea detection, it can be seen that tracheal sound detection can be a useful screening tool to indicate patients in need of more detailed sleep study. (5 refs.)

110111 Real-time acquisition and offline quantitative analysis of cardiac Doppler spectral data: preliminary impressions. G.W.Lighty,Jr., A.S.Pearlman (Div. of Cardiology, Univ. of Washington, Seattle, WA, USA), E.A.Howard. Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.453-6
A prototype system (OASIS) for real-time acquisition, offline storage and analysis of digital Doppler spectral information is being evaluated for clinical research applications. Using commercial hardware components and the UCSD Pascal Operating System, microcomputer-based analysis of Doppler frequency spectra parameters has the potential for improved diagnostic capabilities compared to present analytic methods. Complete Doppler study of all four cardiac valves creates about 1 Mbyte of data. If only significant flow disturbances, detected using qualitative Doppler methods, are quantitated, less data are acquired, but serial comparisons may be compromised. For large volume clinical labs, a separate acquisition system with hard disk storage and tape back-up is suggested. The ability to weight peak and mean frequency measurements by signal amplitude may improve valve gradient and orifice area estimates, while dB thresholds permit timing of prosthetic valve poppet or leaflet motion. The OASIS system represents a powerful research tool. Further software development and definition of algorithms useful in clinical setting will doubtless increase its clinical application. (7 refs.)

87.60G Laser beams, microwaves, and other electromagnetic waves

(inc. NMR; for X-rays and gamma-rays, see 87.60J)

110112 Experimental techiques for direct-contact applicators for microwave hyperthermia. F.Bardati, P.Tognolatti (Dipartimento di Elettronica, Univ. di Roma, Roma, Italy).
Alta Freq. (Italy), vol.52, no.3, p.173-5 (May-June 1983). (4th Italian National Meeting on Applied Electromagnetics, Florence, Italy, 4-6 Oct. 1982).
X- and L-band direct-contact applicators for microwave hyperthermia for cancer treatment have been developed and tested. The reflection coefficient of these applicators, when radiating into the free-space or into a simulated phantom material, has been measured. In order to evaluate the electromagnetic power deposition within biological bodies, the experimental set-ups for both electrical probes measurements and cholesteric plate thermography have been developed. (15 refs.)

110113 Apparatus for RF and microwave hyperthermia. M.Bini, A.Ignesti, L.Millanta, N.Rubino, R.Vanni (Istituto di Ricerca Sulle Onde Elettromagnetiche, CNR, Firenze, Italy), G.Lauri, A.Lenzi, M.Pace, M.Pirillo.
Alta Freq. (Italy), vol.52, no.3, p.176-8 (May-June 1983). (4th Italian National Meeting on Applied Electromagnetics, Florence, Italy, 4-6 Oct. 1982).
Research in progress at IROE and Clinica Chirurgica II for the development of apparatus for local electromagnetic hyperthermia is described. Attention is mainly focused on applicators and thermometric sensors. A 27 MHz apparatus has been developed using a novel type of applicator based on an unbalanced capacitor. Thermometry is essentially based on thermocouples. Thin-wire twisted structure and low-pass RC filter allow control of RF interference and of local temperature perturbation. (8 refs.)

110114 An introduction to medical lasers. J.M.Stamp (Dept. of Medical Phys. & Clinical Engng., Royal Hallamshire Hospital, Sheffield, England).
Clin. Phys. & Physiol. Meas. (GB), vol.4, no.3, p.267-90 (Aug. 1983).
This review deals with the following topics: why use lasers?; what is a laser?; containing and controlling laser beams; types of medical lasers; laser beam delivery systems; evaluation and safety of medical lasers; buying a laser; laser tubes; general maintenance; staff training and safety codes; future outlook. (89 refs.)

110115 Non-invasive fetal monitoring using radiotelemetry. D.J.Albert, H.J.Terry (Medical Phys. Unit, St. James's Univ. Hospital, Leeds, England).
Clin. Phys. & Physiol. Meas. (GB), vol.4, no.3, p.291-8 (Aug. 1983).
A telemetry system for noninvasive monitoring of fetal heart rate and uterine contractions is described. Fetal heart information is obtained by means of Doppler ultrasound, and contractions information using an external tocodynamometer. The more important features of the device are described in detail; the full design is available from the authors. Typical recordings are presented, and the fetal heart rate traces are compared qualitatively with those obtained by direct ECG measurement, with the patient in bed, sitting and walking. The device is now in clinical use. (5 refs.)

110116 The free-electron laser: medicine's rising star. J.T.Riordan.
Photonics Spectra (USA), vol.17, no.7, p.40, 42, 44 (July 1983).
In practical terms, the difference in the free-electron laser's operating principles makes a tremendous difference in its capabilities in comparison with conventional lasers. These differences fall into four main categories: broad tunability, excellent spot size control, excellent pulse width control, and high power density and control. The promise of free-electron lasers falls into two primary areas: laser surgery and photoradiation medicine. In the first instance, it is the extraordinary versatility and control possible with the free-electron laser that make it such an exciting development. The ability to produce a very small spot size makes it easier to get at difficult regions and remove diseased tissue with little damage to surrounding cells. In addition, the tunability of these lasers means that they can be adjusted to precisely meet the wavelength needed for a specific effect on a specific tissue. (no refs.)

110117 Study of craniofacial anomalies with a portable stereo camera. B.S.Savara, Q.D.Clarkson, J.C.Steen, G.F.Gross (Child Study Clinic, School of Dentistry, Oregon Health Sci. Univ., OR, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.2-6 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
This investigation was designed to devise an accurate topographic method for description and comparison of infants and children with craniofacial anomalies. Variations from the norm also could be studied. Biostereometrics was the method of choice. As the infants could not be brought to one central office, a portable stereo camera unit was built. Two 2 1/4″×2 1/4″ cameras were mounted on one base and synchronised to expose simultaneously with the flash unit pointed towards the ceiling. A pair of stereo photographs was obtained. The stereo photographs were used to create a face contour diagram and measured in X, Y, Z coordinates and provided quantitative data in three dimensions which can be used for comparative studies. (1 ref.)

110118 Family of calibrated stereometric cameras for direct intraoral use. S.Curry (Dept. of Growth & Dev., School of Dentistry, Univ. of California, San Francisco, CA, USA), F.Moffitt, D.Symes, S.Baumrind.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.7-14 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
In order to study empirically the relative efficiencies of different types of orthodontic appliances in repositioning teeth in vivo, the authors have designed and constructed a pair of fixed-focus, normal case, fully-calibrated stereometric cameras. One is used to obtain stereo photography of single teeth at a scale of approximately 2:1, and the other is designed for stereo imaging of the entire dentition, study casts, facial structures, and other related objects at a scale of approximately 1:8. Twin lenses simultaneously expose adjacent frames on a single roll of 70 mm film. Physical flatness of the film is ensured by the use of a spring-loaded metal pressure plate. The film is forced against a 3/16″ optical glass plate upon which is etched an array of 16 fiducial marks which divide the film format into 9 rectangular regions. Using this approach, it has been possible to produce photographs which are undistorted for qualitative viewing and from which quantitative data can be acquired by direct digitisation of conventional photographic enlargements. (6 refs.)

110119 Automated system for stereometric analysis of the human face. M.Keefe (Mech. Eng. Dept., Univ. of Minnesota, MN, USA), D.R.Riley, F.W.Worms, T.M.Speidel.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.15-21 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A system that uses stereophotogrammetry to semi-automatically generate three-dimensional facial soft tissue surfaces is presented. The basis of the system is the stereometric technique of direct linear transformation (DLT) which is utilised to eliminate the elaborate instrumentation of present day systems. Automatic digitising using a scanning image analyser requires no hand digitising, and a lightweight headframe provides orientation information for use in evaluating facial changes. The system is computer based to provide graphic images of the resulting data to ease understanding and to provide the beginnings of a large data base concerning human facial form. (6 refs.)

110120 Rapid three-dimensional measurements in clinical dentistry—a new approach. G.W.Butcher, C.D.Stephens (Univ. of Bristol Dental School & Hospital, Bristol, England).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.36-40 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
The conventional method for measuring small objects in three dimensions utilising close range stereo photogrammatic techniques is complex and time consuming. A recent development called the reflex metrograph allows an unskilled operator to collect three dimensional co-ordinates both simply and rapidly. A clinical application to compare in vivo and in vitro measurements showed a similar level of precision. The results compare favourably with a conventional approach. (11 refs.)

110121 Three-dimensional stereometric measurement system using optical scanners, cylindrical lenses, and line sensors. Y.Yamashita (Dept. of Biomedical Engng., School of Medicine, Tokai Univ., Kanagawa, Japan), N.Suzuki, M.Oshima, Y.Yamaguchi.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.67-73 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A simple and low-cost 3-dimensional stereometric measurement system has been developed which measures the shape of the object by means of trigonometry. This system is composed of an X-Y optical scanner, cylindrical lenses and line sensors. A laser beam is incident on an object and is scanned over the area of interest by the optical scanner. Cartesian coordinates of a laser spot hit by the laser beam in a three dimensional space are determined simply and at high speed through the combined use of cylindrical lenses and line sensors. The cylindrical lens makes a line focus and, therefore, the coordinates of a light spot are projected onto a line orthogonal to the axis of the cylindrical lens. The position of the line focus in a line sensor can easily be measured by detecting the photo-cell which indicates the maximum output. Preliminary experiments suggest that the shape of the human torso surface can be measured with fairly good accuracy. (4 refs.)

110122 Contouring of tooth imprints by means of a fluorescence technique adapted to a spatially filtered moire illumination. F.H.M.Jongsma, P.Lambrechts, G.Vanherle (Dept. of Biophys., Univ. of Limburg, Maastricht, Netherlands).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.76-80 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A technique has been developed to produce plane equidistant contouring surfaces on tooth-imprints. This technique consists of spatially filtering a negative obtained by photographing the print under a moire illumination. Unfortunately this technique turned out to be very sensitive for a non-uniform surface reflectivity. To obtain an object-brightness depending only upon the contouring mechanism, the imprint has been coated with a fluorescent dye. A HeCd-laser (λ=422 nm) served as a lightsource for the projection of the moire interference pattern on the imprint. The radiation of the fluorescent coating (λ=530 nm) is used to form an image on the negative. In this way the surface with specular reflection properties is transformed into a Lambertian surface. The spatial filtering technique allows multiple exposures of the final negative enabling an increased depth of field. Contour mappings with a resolution in depth of less than 10 μm have been obtained. (8 refs.)

110123 Automatic topography using high precision digital moire methods. T.Yatagai, M.Idesawa, S.Saito (Inst. of Phys. & Chem. Res., Saitama, Japan).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.81-8 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Three types of moire topographic methods using digital techniques are proposed. Deformed gratings obtained by projecting a reference grating onto an object under test are subjected to digital analysis. The electronic analysis procedures of deformed gratings described enable one to distinguish between depression and elevation of the object, so that automatic measurement of 3-D shapes and automatic moire fringe interpolation are performed. Based on the digital moire methods, the authors have developed a practical measurement system, with a linear photodiode array on a micro-stage as a scanning image sensor. Examples of fringe analysis in medical applications are presented. (21 refs.)

110124 Studying abdomen size and shape variations during pregnancy: an application of moire topography. G.E.Karras (Lab. of Photogrammetry, Nat. Tech. Univ. of Athens, Athens, Greece), K.N.Tympanidis.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.89-91 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
The biostereometric study of body changes can lead to valuable information regarding the metabolism and the physiological development of pregnancy as well as the well-being of the foetus. In this contribution a technique for the calculation of abdomen volume variations from measurements on moire photographs is outlined and experimental results are presented. (4 refs.)

110125 Moire techniques in biomedical case studies. O.D.D.Soares (Centro de Fisica, Faculdade de Ciencias do Porto, Porto, Portugal).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.92-8 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Optical metrology of three-dimensional objects is a subject of major interest for science and technology. Several methods have been proposed and research is being pursued on the study of various principles. The method described employs a coded illumination of the three-dimensional space by fringes projection and the information of the object is decoded with a moire technique. The principle of the method covers a large spectrum of applications. The emphasis for practical applications is given in the field of biomedical studies. The analysis of dismorphosises in static (anatomy) and dynamical (functional) situations is presented, in particular for the study of feet-system and locomotor movement, face aesthetic morphology and trunk studies. Capabilities and advantages of the method are described and demonstrated including video recording. (15 refs.)

110126 Reconstruction of anatomical shapes from moire contourographs. G.G.Saunders (Medical Engng. Resource Unit, Univ. of British Columbia, Vancouver, BC, Canada).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.99-106 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A moire system which rotates an object in front of a slit camera has been used to obtain continuous photographic maps around amputee socket and shoe last shapes. Previous analysis methods required the use of IBM 370 hardware and extensive software overhead. Using a systematic manual digitising technique and user-interactive FORTRAN software, the shape reconstruction has been easily performed on a PDP-11 minicomputer system. Both the digitising technique and the software are oriented towards the shape reproduction process. Numerically controlled machining parameters are used to identify a 'skewed' grid of required points along the cutter path. Linear interpolation and anti-interference techniques resulted in reproduction of shoe lasts to within 0.05 inches (1.2 millimetres) from the sensing axis. Difficulties were experienced in obtaining information to resolve the ends of the shapes. Current efforts focus on circumferential shape sensing of live subjects and automatic digitisation of sensed data. (6 refs.)

110127 Measurement of kyphosis using moire topography. B.Drerup (Orthopadische Univ., Abteilung Biomech., Munster, Germany).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.107-10 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Contour line patterns, as they are produced by moire topography are dependent on position, posture and body shape of the patient. For all medical applications data are needed, which are only dependent on shape and posture and which therefore are independent on positioning. The measurement of the kyphotic angle from topograms can be performed to meet these requirements and to yield results, which are independent of positioning. Different techniques for measuring this angle are discussed. Digitisation and reconstruction of profiles from moire topograms are presented. In order to get reproducible results, landmarks are needed on the body surface. Landmarks may be found either by palpation or by analytical investigation of the back shape. Here, the inflection points of the sagittal back profile are taken as intrinsic landmarks. Their relation to anatomical landmarks, which are found, e.g. by palpation, is studied. (4 refs.)

110128 Analysis of scoliosis by back shape topography. A.R.Turner-Smith, J.D.Harris (Oxford Orthopaedic Engng. Centre, Univ. of Oxford, Oxford, England).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.111-15 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
The use of surface topography for the assessment of scoliotic deformity in the clinic depends firstly on the quality of measures which reliably characterise deformity of the back, and secondly on the ease and speed with which these measures can be applied. A method of analysis of back shape measurements is presented which can be applied to any topographic measurement system. Measures presented are substantially independent of minor changes in the patient's posture in rotation and flexion from one clinic to the next, and yet sensitive enough to indicate significant improvement or degeneration of the disease. The presentation shows (1) horizontal cross-sections at ten levels up the back from sacrum to vertebra prominens; (2) angles of rotation of the surface over a small region about the spine; (3) three vertical profiles following the line of the spine; and (4) measures of maximum kyphosis and lordosis. Extreme care in positioning the patient is unnecessary and those spinous processes which are easily palpable, the vertebra prominens and the two dimples over the posterior superior iliac spines are marked. Analysis proceeds entirely automatically once the basic shape data have been supplied. Applications of the technique to indirect moire topography and a television topographic measurement system are described. (22 refs.)

110129 Stereophotogrammetric method for breast cancer detection. D.B.Sheffer, R.E.Herron, W.M.Morek, F.Proietti-Orlandi (Inst. for Biomed. Engng. Res., Univ. of Akron, Akron, OH, USA), C.W.Loughry, R.H.Hamor, R.A.Liebelt, R.S.Varga.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.120-4 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
This study reports on 29 patients (58 breasts), selected in a stratified manner to include 7 cancers, 13 benign tumours and 38 apparently normal breasts, that were subjected to biostereometric analysis. This process consisted of analysis in a blind setting of contour mammograms made from stereophotographs of the breast which resulted in the correct identification of all 7 cancers, 11 of the 13 benign tumours and 30 of the remaining 38 normal breasts. There were 8 false positives identified. This study, in conjunction with a previous study, indicates that the biostereometric analysed contour mammograms have the potential to be developed into a process for breast cancer screening. Suggested areas for further study include volume differences in individual breasts as well as the volume differences in individual breast slices and their relationship to breast pathology. (6 refs.)

110130 Automatic measurement of body surfaces using rasterstereography. E.Hierholzer, W.Frobin (Abteilung Biomech., Orthopadische Univ. Munster, Munster, Germany).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.125-31 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
The measurement of three-dimensional body shape is of considerable interest in orthopaedic applications, for example the assessment of spinal deformities from the shape of the back surface. At present these measurements are mostly carried out using optical methods such as stereophotogrammetry or moire topography. The image data acquisition is generally performed by hand. However, due to the large number of measurement points necessary for a satisfactory representation of a surface, this procedure is very tedious and time consuming. In contrast to this, rasterstereography using a line raster enables considerable time savings by automated image scanning. The method of rasterstereography is briefly explained. Due to the simple structure of line rasterstereographs an automatic image evaluation is relatively easy. The evaluation procedure consisting of image scanning (using a CCD sensor camera), line detection, line pattern analysis and three-dimensional surface reconstruction is outlined. Examples of back surface measurements in the case of spinal deformities are presented. (4 refs.)

110131 Holographic three-dimensional hard copy for medical computer graphics. B.E.Keane (Dept. of Medical Phys., Royal Sussex County Hospital, Brighton, England).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.164-8 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A computer graphics array may contain all the information required for a three-dimensional display but conventional VDUs (video display units) and printers can only provide a flat image. The problem is approached by converting the computer output into a form suitable for synthesis of a volume hologram. Suitable methods and apparatus are discussed and typical results presented, including CT (computer tomography) scan in radiotherapy treatment planning and radiological architecture applications. (3 refs.)

110132 Television scanning technique for topographic body measurements. A.R.Turner-Smith (Oxford Orthopaedic Engng. Center, Univ. of Oxford, Oxford, England).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.279-83 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A television/computer system is used to measure the apparent distortion of a line of light as it is scanned over an object. A projector and camera are fixed relative to one another in a swinging frame which rotates at a constant speed through a vertical arc. The displacement of the line in the television picture is a function of the distance of the object from an imaginary cylinder about the axis of rotation, while the position of the frame is also read by the television interface from a spot inserted into the video signal. The geometrical configuration of camera, projector and frame allows simple analysis of the data to yield an output consisting of scattered three-dimensional points. Calibration is achieved by measuring an object of known dimensions. The use of the system is illustrated by application to a project for the assessment of scoliotic deformity of the back. (20 refs.)

110133 Algorithms for two-camera video motion analysis. J.Au, J.Pugh (Dept. of Orthopaedics, Hospital for Joint Diseases Orthopaedic Inst., New York, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.314-20 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
The efficiency of any motion analysis is largely dependent on the software generated for the specific purposes intended. Many of the problems in acquiring and analyzing data with computers of limited memory can be circumvented by clever algorithms. Several algorithms for two-camera video motion analysis are discussed in detail. These algorithms are intended for resolution of problems that include video ghosts, blockage of data points by extraneous movement of ancillary body parts, statistical techniques to improve accuracy, efficient searching routines, and calibration programs. All of these algorithms have been implemented as specific programs in a complete system intended for the analysis of the parameters of human motion. (5 refs.)

110134 Contour photography of the optic nerve head: stereometric basis. J.M.Shapiro (Dept. of Ophthalmology, Boston Univ. School of Medicine, Boston, MA, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.322-3 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Considers the relationships among the variables which determine the stereo base in contour photography. It is shown how the coefficient of variation of the topographic measurements may be minimized. (no refs.)

110135 Stereo measurement of the ocular fundus in ophthalmology. T.Takamoto, B.Schwartz (Dept. of Ophthalmology, Tufts-New England Medical Center, Boston, MA, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.324-9 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Glaucoma, a common cause of blindness, can be detected in the early stages by studying topographic changes or cupping in the optic disc. The direct observation of fundus using an ophthalmoscope or the evaluation of the disc in fundus photographs has been primarily subjective, differing considerably from observer to observer. The authors have, therefore, developed an objective quantification technique—the photogrammetric radial section method, which can quantitate not only cupping or swelling of the optic nerve, but also the growth of tumor or the development of posterior staphyloma in the myopic eye. With the radial section method the authors have computed a new cup parameter, slope, from stereopairs of five normal eyes. The averages of the coefficients of variation for the following parameters, derived from measurements of the cup slopes of five normal eyes, were: 3.3% for the peripapillary retina; 5.7% for the neural rim; 3.1% for the cup wall; and 4.0% for the cup bottom. (14 refs.)

110136 Diagnostic NMR. R.W.Redington (Corporate Res. & Dev. Center, General Electric Co., Schenectady, NY, USA).
IEEE Trans. Med. Imaging (USA), vol.MI-1, no.4, p.230-3 (Dec. 1982). [received: Sept. 1983]
A general discussion of diagnostic NMR is given including in vivo chemical shift spectroscopy and NMR imaging. The way in which General Electric became involved in diagnostic NMR is described. (3 refs.)

110137 A NMR tomograph electromagnet design. P.Holec.
Elektrotech. Cas. (Czechoslovakia), vol.34, no.7, p.458-70 (1983). In Czech.
The paper deals with magnetic field homogeneity problems of NMR tomography. The differences between idealized and real conditions are analyzed and a new construction is presented, allowing one to find the optimum position of electromagnet coils by a simple algorithm. (11 refs.)

110138 A combined light and scanning electron microscopy on human urinary cytology. H.Kumon, Y.Nasu, Y.Matsumura, H.Ohmori (Dept. of Urology, Okayama Univ. Medical School, Okayama, Japan), T.Tanaka.
J. Electron Microsc. (Japan), vol.32, no.1, p.27-32 (1983).
Approximately 250 bladder-washing and voided urine specimens from normal, and inflammatory and malignant lesions were examined using light microscopy (LM), scanning electron microscopy (SEM) and a newly-designed mesh. This mesh, containing 42 compartments in 25 mm^2 on gelatine-coated glass-slip, permitted the authors to directly correlate LM and SEM images. With SEM, malignancy of exfoliated urothelial cells mainly depended on the presence or absence of pleomorphic cytology was proposed. (13 refs.)

110139 Microwave thermography—characteristics of waveguide applicators and signatures of thermal structures. M.Robillard, M.Chive, Y.Leroy (Centre Hyperfrequences et Semiconducteurs, Univ. des Sci. et Tech. de Lille I, Villeneuve d'Ascq, France), J.Audet, Ch.Pichot, J.Ch.Bolomey.
J. Microwave Power (Canada), vol.17, no.2, p.97-105 (June 1982).
Studies the problem of the interpretation of the signals provided by microwave thermography, which allows the detection of the thermal gradients in living tissues. These signals correspond to the thermal noise measured by a radiometer when the probe scans the surface of the tissues (passive process).

The paper describes how these signals can be computed by means of a new method based on the antenna reciprocity principle. This process requires a knowledge of the electrical field distribution in the lossy medium when the applicator is radiating a microwave signal (active process). Examples of computations of the thermal signals and experimental verifications are presented. Then, the paper introduces a new concept of 'thermal signature' and shows how it is possible to reach a quantitative interpretation of the thermal signals such as those obtained in clinical investigations (thermal pattern recognition). (29 refs.)

110140 The role of thermal imaging in the diagnosis, treatment and prognosis of pain. R.Rizzi (Dept. of Anaesthesia, Reanimation & Pain Therapy, Regional Hospital of Vicenza, Vicenza, Italy), F.Merlo.
Medicamundi (Netherlands), vol.27, no.3, p.133-5 (1982).
A report is presented on the use of thermography in a pain therapy centre. The technique offers safe and non-invasive method for the diagnosis and prognosis of a wide spectrum of pain associated with disorders of the somatic nervous system and the vegetative system, and forms a valuable aid to treatment. The results obtained are demonstrated with the aid of several thermograms. (5 refs.)

110141 Microprocessor-based image processing system for dynamic foot pressure studies. C.I.Franks, R.P.Betts, T.Duckworth (Royal Hallamshire Hospital, Sheffield, England).
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.566-72 (Sept. 1983).
A microprocessor-based system is described for data capture and analysis of dynamic foot pressure images. A run-length encoding video digitiser captures up to 32 frames at a rate of 25 per second and stores the data in memory. These data are displayed on a colour monitor and can be analysed to produce pressure against time curves or printed or plotted as isopressure contour plots. (9 refs.)

110142 Analysis of resonant coupled coils in the design of radio frequency transcutaneous links. N.deN.Donaldson, T.A.Perkins (Medical Res. Council, Neurological Prostheses Unit, London, England).
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.612-27 (Sept. 1983).
A theory of coupled resonant coils has been developed which makes possible the design of radio frequency transcutaneous links of simultaneously high overall efficiency and good displacement tolerance while keeping circuitry simple (particularly in the implanted receiver). Series-tuned transmitter coils were used, obtaining high efficiency. In the first example a stimulator which has excellent displacement tolerance because it works at critical coupling is designed. The second example shows how the theory was used when the voltage in the implant was regulated. The design process involves ad hoc compromises between disparate quantities (e.g. efficiency against voltage transfer ratio), rendering a standard design procedure unsuitable. Fortunately, the derived theoretical formulae are simple enough for every design to be considered from fundamentals, based on coil parameters. Extensive coil loss data are presented here for the frequency band 0.2 to 20 MHz. (10 refs.)

110143 Radiofrequency-induced hyperthermia: computer simulation of specific absorption rate distributions using realistic anatomical models. D.W.Armitage (Dept. of Electronic Engng. Sci., Univ. Coll. of North Wales, Bangor, Wales), H.H.LeVeen, R.Pethig.
Phys. Med. & Biol. (GB), vol.28, no.1, p.31-42 (Jan. 1983). [received: Sept. 1983]
A description is given of a computer simulation technique which predicts the specific absorption rate (SAR) distribution within the human body resulting from the application of radiofrequency electromagnetic energy. The method uses an extension to the principle of over-relaxation of electric potentials and the basis of the simulation is a realistic three-dimensional model derived from both dielectric and anatomical data. Two of the principal means of applying radiofrequency hyperthermia, namely the use of capacitive electrodes and inductive coils, have been provided for. The accuracy of the simulation has been favourably tested using an agar split-phantom and an infrared thermograph camera. The simulations can be used to assist the design and clinical use of radiofrequency applicators, and examples are given of the application of both an inductive coil and switched capacitive electrodes to heat the thorax. (28 refs.)

110144 Imaging system using gradient index fibers: a tutorial. [Medical imaging]. T.R.Hsing (Telecommunication Res. Lab., Waltham, MA, USA).
Proceedings of the Second International Conference and Workshop on Picture Archiving and Communication Systems (PACS II) for Medical Applications, Kansas City, MO, USA, 22-25 May 1983 (New York, USA: IEEE 1983), p.46-53 (24 refs.)

87.60J Corpuscular radiation and radioisotopes

(inc. X-rays and gamma-rays)

110145 Stereotactic implantation of radioactive sources for the treatment of brain tumours. C.Karolis (Dept. of Medical Phys., Prince of Wales Hospital, Randwick, NSW, Australia), P.S.Reay-Young, F.C.G.Southon, J.Matheson.
Australas. Phys. & Eng. Sci. Med. (Australia), vol.6, no.2, p.59-63 (April-June 1983). [received: Aug. 1983]
The authors discuss their experiences in the treatment of recurrent brain tumours with Au-198 seeds in temporary implants. Included in the discussion is a description of stereotactic geometry and instrumentation; the application of computerised axial tomography for planning; the efficacy of the authors' choice of isotope and method and the radiation protection problems encountered with the procedure. The authors conclude that this treatment has a role to play in the management of selected brain tumours, but would recommend the use of after loading techniques and high activity I-125 to minimise radiation protection problems. (5 refs.)

110146 Examination of vocal fold movement by ultra-short pulse X-radiography. N.J.Noscoe (Dept. of Oncology, Middlesex Hospital Medical School, London, England), A.J.Fourcin, N.J.Brown, R.J.Berry.
Br. J. Radiol. (GB), vol.56, no.669, p.641-5 (Sept. 1983).
Antero-posterior radiographs of the larynx lack spatial and temporal resolution, due to the movement of the vocal folds during phonation. By utilising the electrolaryngograph to monitor vocal fold movement, single X-ray pulses of 30 nanoseconds duration have been triggered at predetermined points during the cycle of vocal field movement to visualise these in normal phonation. (8 refs.)

110147 Fast neutron therapy at Edinburgh: staff protection. D.E.Bonnett (MRC Cyclotron Unit., Western General Hospital, Edinburgh, Scotland).
Br. J. Radiol. (GB), vol.56, no.669, p.665-72 (Sept. 1983).
The major hazards encountered by staff using neutrons for radiotherapy are discussed. Specific reference is made to the experience gained at the MRC Cyclotron Unit at the Western General Hospital, Edinburgh, using neutrons generated by the d(15 MeV)+Be reaction. The neutron therapy facility consists of a cyclotron and both a fixed horizontal and an isocentric therapy beam, and staff protection during five years' operation is reviewed. Levels of induced activity in the cyclotron and therapy equipment are reported and problems of radioactive contamination discussed. Summaries of whole-body and finger dose equivalents received by engineering staff, and of whole-body dose equivalents received by physics and radiography staff, are presented and analysed. It is shown that, although doses received by staff are higher than for staff in an X-ray facility, they are all well below the maximum permissible levels, and it is also concluded that radioactive contamination of staff is minimal. (4 refs.)

110148 A single isotope method of post-prandial duodenogastric reflux assessment using ^{99}Tc^{m}-labelled IDA in patients with gallstones. I.A.Eyre-Brook (Dept. of Surgery, Royal Hallamshire Hospital, Sheffield, England).
Clin. Phys. & Physiol. Meas. (GB), vol.4, no.3, p.299-307 (Aug. 1983).
A technique for the quantitative assessment of post-prandial duodenogastric bile reflux is described using a single isotope ^{99}Tc^{m} and a single-channel large-field gamma camera with a data processing system. The stomach is localised with pertechnetate prior to IDA administration and duodenogastric reflux is calculated as the percentage of hepatic IDA output reaching the stomach after correction for background activity and hepatic overlap. The technique has been validated, and used to study reflux in 25 patients with gallstones and in 10 control patients. Gall bladder function was assessed with an oral cholecystogram. Marked reflux ($>7\%$) occurred in 5 out of 9 patients with a nonfunctioning gall bladder, but in no controls and in none of 16 patients with gallstones in a functioning gall bladder. When patients were studied again after cholecystectomy, 2 patients with normal functioning gall bladders had developed marked reflux while those with preoperative reflux continued to reflux after cholecystectomy. Symptoms of gallstone dyspepsia before operation were more severe in those with marked reflux than those without. Surgery improved these symptoms even in those who continued to reflux after operation. (8 refs.)

110149 Roentgen stereophotogrammetry in orthopedics. G.Selvik (Dept. of Anatomy & Diagnostics Radiology, Univ. of Lund, Lund, Sweden).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.178-85 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A system for Roentgen stereophotogrammetry has been used in Lund, Sweden, since August 1972, and by August 1982 ten thousand stereo films were evaluated using this method. The skeletal parts investigated have been permanently marked with tantalum balls 0.5 or 0.8 mm in diameter. The causes for the investigation were bone growth disorders in the lower extremity (134 patients), spinal fusions (35 patients), high tibial osteotomies for gonarthrosis (21 patients) and endoprosthetic replacement of the knee (68 patients) or hip (42 patients) joint. By Roentgen stereophotogrammetric analysis (RSA), information on, for instance, the development of angular deformities and staple loosening in the leg, the healing process of the intended fusion in the spine or at the knee, and on the migration and stability of prosthetic components, have been obtained. RSA is of value both for prognostic and follow-up purposes, and is versatile enough in a proper setting to be used for routine clinical investigation. (58 refs.)

110150 Single image X-ray photogrammetry system used to detect total joint loosening. F.G.Lippert, S.A.Veress, R.M.Harrington, T.El-Garf (Dept. of Orthopaedics, Veterans Administration Medical Center, Seattle, WA, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.186-92 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Loosening is the number one complication of total joint replacements. A direct method of measuring small motions between the prosthetic implant and the surrounding bone would allow the surgeon to evaluate replacement surgery or activity restrictions. Single plane X-ray photogrammetry uses stainless steel markers in the bone and prosthetic implant and a control frame in order to accomplish this measurement. Testing of models representing a total hip replacement and total knee replacement has shown that displacements can be measured with a root mean square error of less than 0.2 mm. (no refs.)

110151 Method for determining in-vivo ligament lengths from biplanar X-rays with incomplete data. T.S.Buchanan (Biomed. Engng. Center, Northwestern Univ., Evanston, IL, USA), A.F.Mak, J.L.Lewis.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.193-9 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A noninvasive biplanar radiographic technique for in-vivo determination of ligament lengths is presented. By taking biplanar X-rays of a human subject joint and locating the images of prominent bony reference points on the films, the three-dimensional locations of these points are determined. A unique scaling method is employed that compares the coordinates of the reference points with those previously obtained from a cadaver. Scaling equations that describe the subject joint in terms of the cadaver joint allow reference points to be clearly visible in only one X-ray view. The origin and insertion of ligament points from the cadaver are mapped onto the subject's joint and the ligament length is taken as the distance between the two. An application of this technique to the human knee joint is presented. (7 refs.)

110152 Dedicated stereophotogrammetric X-ray system for craniofacial research and treatment planning. S.Baumrind (Dept. of Growth & Dev., School of Dentistry, Univ. of California, San Francisco, CA, USA), F.Moffitt, S.Curry, R.J.Isaacson.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.200-9 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
The authors have constructed and brought into use what they believe to be the first dedicated coplanar craniofacial stereometric X-ray system for clinical use. Paired Machlett Dynamax 50/58 X-ray tubes with 0.3 mm focal spots are employed. Displacement between emitters is 16 inches. The focus film distance for both emitters is 66.5 inches. The mid-sagittal plane to focus distance is 60 inches. One film of each stereo pair conforms with the standards of the Second Roentgenocephalometric Workshop and can be used to make all standard two-dimensional orthodontic and cephalometric measurements. When supplemented by data from the conjugate film, a three-dimensional coordinate map can be generated as a machine operation. Specialized complementary software has been developed to increase the reliability of landmark location both in two and in three dimensions. (5 refs.)

110153 Stereoentgenographic system with portable calibration cage for use in clinical medicine. F.Moffitt (Dept. of Civil Engng., Univ. of California, Berkeley, CA, USA), Baumrind S., N.Chafetz, S.Curry.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.210-16 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
For the past five years, the authors have been accumulating information on the performance of a stereoentgenographic system developed for use in clinical medicine and first reported at the NATO Symposium on the Application of Human Biostereometrics (Paris, 1978). This system represents an adaptation of normal case coplanar stereometry and involves the use of a single emitter which is displaced in a controlled fashion between exposures. The system has been used primarily for the detection of applicance loosening and settling following the placement of total hip protheses and also for the detection of pseudorthosis following lumbo-sacral fusion. One major goal has been the development of a data acquisition and analysis system suitable for general hospital use which can be operated by technicians without specialized photogrammetric training. This report focuses on system design and on the delineation of technical problems encountered during routine clinical use of the system. (5 refs.)

110154 Establishing quantitative within-subject confidence limits for clinical stereoentgenographs. E.L.Korn (Dept. of Biomaths., School of Medicine, Univ. of California, Los Angeles, CA, USA), S.Baumrind, N.Chafetz, N.Curry, F.Moffitt.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.217-23 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
It is not quite clear that under ideal conditions, discrete points can be located on X-ray films with standard deviations of less than 50 μ. However, under routine clinical conditions, such considerations as individual variation in anatomy, movement of the subject between exposures, and variations in image quality combine to produce considerable reductions in the confidence which can be placed in quantitative assessments made from stereoentgenographic films. This paper discusses some considerations involved in designing mathematical models in such a way as to optimize the use of imperfect data in answering specific clinical questions. (13 refs.)

110155 Accuracy of stereometry in assessing orthognathic surgery. G.E.King, R.A.Bays (Dept. of Biomed. Engng., Medical Coll. of Georgia, Augusta, GA, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.224-8 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
An X-ray stereometric technique has been developed for the determination of 3-dimensional coordinates of spherical metallic markers previously implanted in monkey skulls. The accuracy of the technique is better than 0.5 mm. and uses readily available demountable X-ray equipment. The technique is used to study the effects and stability of experimental orthognathic surgery. (3 refs.)

110156 X-ray photogrammetry for endocavitary radiation therapy. E.Baj Agnoletto (Istituto di Topografia Fotogrammetria e Geofisica, Politecnico di Milano, Milano, Italy), U.Cerchiari, A.E.Sichirollo.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.229-32 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
X-Ray photogrammetry has been applied to reconstruct the disposition of the radioactive sources in a patient to be treated by endocavitary radiation therapy. It is concluded that the X-ray photogrammetric method has enabled improvements to be madè compared with previous dosimetric studies. Moreover it enables one to evaluate the errors made in the plotting of radioactive sources and to correct the results obtained. (5 refs.)

110157 Advances in nuclear medicine. R.G.Evens (Mallinckrodt Inst. of Radiology, Washington Univ., St. Louis, MO, USA).
IEEE Trans. Med. Imaging (USA), vol.MI-1, no.4, p.223-5 (Dec. 1982). [received: Sept. 1983]
The author tries to put into clinical relevance a portion of diagnostic imaging. He discusses nuclear medicine, which did not really come about until after World War II. He gives an introduction to, and discusses the clinical use of, this branch of medicine. Over the last twenty-five years the major improvements have been in the technology of what is injected. Highly sophisticated radiopharmaceuticals have been utilized to go to specific organs, along with real improvements in the electronic imaging devices used. (no refs.)

110158 Relationship between regional pertechnetate cerebral circulation time and EEG in patients with cerebral infarction. U.Tolonen, A.Ahonen (Dept. of Clinical Neurophysiology, Univ. of Oulu Central Hospital, Oulu, Finland).
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.125-32 (Aug. 1983).
The qualitative and regional correlations between the EEG and the cerebral circulation time (CCT), obtained by using intravenously injected pertechnetate and a multidetector device, were studied in 75 patients with supratentorial cerebral infarction. Overall good correlations could be demonstrated between both inter- and intrahemispheric CCT abnormalities and the EEG, though not in all patients. The number of patients with pathological CCT findings showed a tendency to increase with increasing severity of the EEG abnormality. The number of abnormal CCT areas per patient (indicating the size of the circulation disturbance) also increased significantly with increasing severity of the EEG disturbance. The present study on cerebral infarction, though using intravenously injected pertechnetate for the CCT measurement, showed a reasonable correspondence with earlier reports on the relationship between the EEG and either the cerebral blood flow or the CCT (obtained by intraarterially injected isotope). This would seem to suggest that the non-invasive method used for regional CCT measurement has potential for evaluation of cerebral haemodynamics. (22 refs.)

110159 Radioisotopes for the treatment of cancer. C.B.G.Taylor (IAEA Lab., Seibersdorf, Austria).
Int. At. Energy Agency Bull. (Austria), vol.25, no.2, p.3-6 (June 1983).
Gives a short history of radiotherapy for cancer, particularly of the cervix. Teletherapy techniques and equipment are discussed. (no refs.)

110160 A modern universal angiography installation with a 14 in. image intensifier. H.C.Rucker (Radiologische Abteilung, Klinik Roderbirken, Leichlingen/Rhld., Germany), M.K.Jalloul.
Medicamundi (Netherlands), vol.27, no.3, p.111-18 (1982).
Modern technological refinements enable all vascular regions to be examined using medium-format fluorography, combined with a 14 in. image intensifier. A versatile angiography system is described in which a large-field image intensifier and a generator with automatic dose-rate control enable examinations to be carried out efficiently, and with the minimum of stress for the patient. The design of the system also permits optimal integration of digital subtraction angiography. (8 refs.)

110161 Computerized dual-energy imaging: a technical description. J.Coumans, J.Kosanetzky (Philips Res. Lab., Hamburg, Germany), F.W.Zonneveld.
Medicamundi (Netherlands), vol.27, no.3, p.125-32 (1982).
X-ray attenuation is material- and energy-dependent. In general, energy dependence is ignored, or regarded as understandable, because it leads to unwanted spectral artifacts and unreliable quantitative values in computed X-ray images. This article describes the practical application of energy dependence in computed tomography and computed radiography for providing reliable quantitative image information, inherently free of spectral artifacts, in addition to the usual qualitative visual information. A switched-voltage dual-energy technique is employed. Some of the new diagnostic possibilities offered by the technique are discussed, including the synthesis of mono-energetic images with enhanced contrast, and bone/soft tissue densitometry. (9 refs.)

110162 Image reconstruction methods from transaxial tomographic samples: frequency domain techniques. C.R.Padron (Univ. Politecnico de Madrid, Madrid, Spain), M.A.M.Fernandex, J.A.Martin Pereda.
Mundo Electron. (Spain), no.131, p.93-100 (Sept. 1983). In Spanish.
Transaxial tomography is a radiographic technique that provides an image of an isolated two-dimensional section of a three-dimensional object. The basic principles of this technique and a general view of the reconstruction methods based on Fourier analysis are reviewed; discrete versions for the treatment with digital computers are also shown. (14 refs.)

110163 New method to calculate the renal transit time spectrum from conventional three-probe renography. R.Gullquist, H.Abrahamson, R.Brandt (Dept. of Clinical Physiology, St. Erik's Hospital, Stockholm, Sweden), J.Philip, T.Strandell.
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.599-602 (Sept. 1983).
A model of the kidneys and the systemic blood pool is constructed to derive the renal transit time spectrum from data obtained from three-probe renography. The transit time spectrum is derived by a deconvolution technique based on the maximum likelihood method. The computations were done on a microcomputer, and the c.p.u. time for solving two transit time spectra was mostly less than 5 min when 50 averaged sample points per measuring detector were used. The method is shown to be very insensitive to statistical noise, which is generally a problem using deconvolution techniques. The averaging of samples was done to save memory and reduce c.p.u. time, but no further filtering procedure or blood background subtraction was needed prior to execution of the algorithm. (8 refs.)

110164 Spot-camera of Medicor Works, type: SPOT-1. M.Csontos.
Medicor News (Hungary), vol.15, no.4, p.87-93 (1982).
Summarizes the importance of the spot-cameras used for X-ray systems built up with an image converter and an image intensifier. The spot-camera manufactured by Medicor Works, which makes exposures on cut-film of 100 mm by 100 mm size, is described. It is suitable for making single and serial exposures. In serial operating mode the device makes two exposures in a second. The simplicity of the device, as well as the simple elimination of the pullbacks occasionally caused by the motion of the film is also emphasized. The mechanical and electrical operation of the camera, as well as its main technical data are considered in detail. (no refs.)

110165 Subsequent addition of a spotfilm camera to existing X-ray equipment with image intensifier.
Medicor News (Hungary), vol.15, no.4, p.94-6 (1982).
The BK9/6/4-1 devices of Medicor Works are single-channel X-ray systems with a TV which are suitable for fluoroscopy only. The conversion of these devices to the BK9/6/4-2B two-channel system by the addition of a spotfilm camera (type SPOT-1) is described. This conversion enables radiographs to be made. (no refs.)

110166 Tissue-air ratios and scatter-air ratios for diagnostic radiology (1-4 mm Al HVL). R.M.Harrison (Regional Medical Phys. Dept., Newcastle upon Tyne, England).
Phys. Med. & Biol. (GB), vol.28, no.1, p.1-18 (Jan. 1983). [received: Sept. 1983]
Tissue-air and scatter-air ratios for use in diagnostic radiology (1-4 mm Al HVL) have been calculated from previously reported measurements of percentage depth doses (PDD) and backscatter factors (BSF) for the same quality range. Tabulations of TAR are presented. The calculated TARs are compared with direct measurements of TAR which have been carried out by other workers. TARs and SARs are shown to be functions of peak tube potential for a given first HVL as a consequence of a similar dependence of PDD. This emphasises once again the inadequacy of the first HVL alone as a specifier of beam quality. (9 refs.)

110167 An efficient method of randomly sampling the coherent angular scatter distribution. J.F.Williamson (Dept. of Therapeutic Radiology, Univ. of Minnesota Hospitals, Minneapolis, MN, USA), R.L.Morin.
Phys. Med. & Biol. (GB), vol.28, no.1, p.57-62 (Jan. 1983). [received: Sept. 1983]
Monte Carlo simulations of photon transport phenomena require random selection of an interaction process at each collision site along the photon track. The possible choices are usually limited to photoelectric absorption and incoherent scatter as approximated by the Klein-Nishina distribution. Coherent scattering events are usually ignored. One reason for this omission is the lack of documentation in the medical physics literature concerning an efficient and accurate procedure for sampling the coherent angular scatter distribution. The authors describe a technique to accomplish this task. Although similar methods have been described elsewhere (Cashwell et al. 1973, Chan 1981), the authors feel this technique should be made more easily available to the medical physics community. (9 refs.)

110168 A general method for three-dimensional filter computation [positron emission tomography application]. B.Schorr, D.Townsend, R.Clack (DD Div., CERN, Geneva, Switzerland).
Phys. Med. & Biol. (GB), vol.28, no.9, p.1009-19 (Sept. 1983).
Application of the Fourier space deconvolution algorithm to three-dimensional (3D) reconstruction problems necessitates the computation of a frequency space filter; which requires taking the 3D Fourier transform of the system response function. In this paper, it is shown that for system response functions of the specific form $d(\theta,\phi)/r^2$, with $d(\theta,\phi)$ an angular function describing the imaging system, the filter computation can always be reduced to single integration which, in many cases, may be performed analytically. Complete expressions are derived for the general 3D filter, and two examples are given to illustrate the use of such expressions. (7 refs.)

110169 An investigation into the presence of secondary electrons in megavoltage photon beams [radiotherapy application]. P.J.Biggs, M.D.Russell (Dept. of Radiation Medicine, Massachusetts General Hospital, Boston, MA, USA).
Phys. Med. & Biol. (GB), vol.28, no.9, p.1033-43 (Sept. 1983).
The presence of secondary electrons in photon beams of ^{60}Co and 4, 8, 10 15 and 25 MV X-rays has been studied by measuring surface charge using thin window ionisation chambers. Measurements have been made for square fields from 4×4 cm^2 to 35×35 cm^2 for locations from the collimator head to a

distance of 4 m from the target. In addition, measurements have been made from rectangular fields at 10 MV and 25 MV for fields of equivalent area from 5×5 cm^2 to 25×25 cm^2. By eliminating the inverse square effect, the presence of contaminants from the head and the effect of build-up in air are clearly seen and well separated. Comparison between the curves at different energies indicates an increasing effect of contamination from the head with energy and a decreasing effect of electron production in air with increasing energy. (8 refs.)

110170 A comparison of attenuation correction methods for quantitative single photon emission computed tomography. S.Webb, M.A.Flower, R.J.Ott, M.O.Lech (Dept. of Phys., Royal Marsden Hospital, Sutton, England).
Phys. Med. & Biol. (GB), vol.28, no.9, p.1045-56 (Sept. 1983).
Transverse section tomograms of experimental phantoms and patients have been obtained using a GE 400T camera and a filtered back-projection reconstruction technique. These tomograms have been compared with the corresponding sections reconstructed from the same tomographic projection data, but using iterative algorithms with correction for photon attenuation. The comparison assesses the importance of including a correction for attenuation as well as demonstrating how closely a simple geometric attenuation correction, applied to the filtered back-projection reconstruction method, approximates to a more accurate correction incorporated in the computation of line integrals during iterative reconstruction. A comparison is also made between the behaviour of reconstruction algorithms with simulated projection data and real data in terms of convergence properties, and some shortcomings arising from simulation are noted. (15 refs.)

110171 Grid weight as an index of radiographic exposure factors. J.Hale (Hospital of the Univ. of Pennsylvania, Philadelphia, PA, USA).
Phys. Med. & Biol. (GB), vol.28, no.9, p.1075-6 (Sept. 1983).
An investigation of the catalogues of the major X-ray equipment suppliers in the United States showed that while all manufacturers provide information on grid ratio and strip density, only one gives specifications for grid weight. The author feels that this is unfortunate because this descriptor is an excellent indicator of both the clinical value of the grid for enhancing contrast and the radiographic exposure factors required for a particular grid. (2 refs.)

110172 Clinical application of auto edge detection cardiac analysis program. K.Higashi, M.Kousaka, S.Kobayashi, S.Hamada, T.Nishiki, I.Yamamoto (Dept. of Radiology, Kanazawa Medical Univ., Kahoku-gun, Ishikawa, Japan).
Radioisotopes (Japan), vol.32, no.6, p.289-92 (June 1983). In Japanese.
Using a Siemens Gamma Sonic data processing Scintiview an auto-edge cardiac analysis program (ACAP) was developed. It relies on area of interest detection using first and second differentials of the profile curve of the left ventricle. Using a weighting factor, alpha, and background subtraction, an ejection fraction is obtained. ACAP was experimentally compared to Cardiac Analysis Program II in 10 patients. Data on ejection fraction (EF), pixel number of end diastolic left ventricle, end diastolic count, end systolic count, end systolic and diastolic count are plotted, EF reproducibility with ACAP was 100%. Problems remained with alpha values of less than 0.3 and greater than 0.6 and achieving high enough counts for short data collection times. (3 refs.) *M.O.*

110173 A scaling method for a system of linear equations—its application to computerised tomography reconstructed from a small number of projection views. F.Kobayashi, S.Yamaguchi (Faculty of Engng., Tokyo Inst. of Technol., Tokyo, Japan).
Trans. Inst. Electron. & Commun. Eng. Jpn. Part D (Japan), vol.J66D, no.5, p.549-56 (May 1983). In Japanese.
The best way to scale a matrix is to make the condition number of the transformed matrix as small as possible. From this point of view, the authors propose a new method of scaling linear equations. A coefficient matrix is transformed by an orthogonal transform procedure and then the transformed matrix is equilibrated before a linear-system solver is applied. The new method is applied to scaling numerical examples of ill-conditioned systems of equations. The convergence of the conjugate gradient method in these equations is shown to be greatly influenced by scale effects. The proposed method is useful to computed tomography reconstructed from a small number of X-ray projection views. (15 refs.)

110174 Digital cardiovascular fluoroscopy: a low cost system for development of computer analysis techniques. M.Baroni, G.Coppini, G.Valli (Inst. of Clinical Physiology, CNR, Pisa, Italy).
Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.497-500
Recently, in X-ray angiocardiography several advances have been made with video digital systems. However, to prevent loss of diagnostic information due to digitization, relatively high cost machines have been developed. Thus, a useful approach is to study a minimal set of specifications, trading off between spatial and temporal resolutions, and to develop flexible image processing software. With this aim, the features and performances of the digital angiographic system are presented. X-ray equipment is computer controlled to improve performance, such as the minimization of dose, quantum noise and motion blur. A package of application software is described. (9 refs.)

110175 Depth dosimetry of curved radon-222 plesiotherapy applicators. R.G.S.Taylor (Dept. of Phys. Sci., Queensland Radium Inst., Herston, Australia).
Australas. Phys. & Eng. Sci. Med. (Australia), vol.6, no.2, p.94-5 (April-June 1983). [received: Aug. 1983]
The measurements described were carried out to solve the problem of the high measured values of maximum dose delivered by doubly-curved Radon-222 applicators. Minimum and maximum depth doses are discussed. (5 refs.)

110176 Neutron fluence-to-dose equivalent conversion factors: a comparison of data sets and interpolation methods. C.S.Sims, G.G.Killough (Health and Safety Res. Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA).
Radiat. Prot. Dosim. (GB), vol.5, no.1, p.45-8 (1983).
Various segments of the health physics community advocate the use of different sets of neutron fluence-to-dose equivalent conversion factors as a function of energy and different methods of interpolation between discrete points in those data sets. The major data sets and interpolation methods are used to calculate the spectrum average fluence-to-dose equivalent conversion for five spectra associated with the various shielded conditions of the Health Physics Research Reactor. The results obtained by use of the different data sets and interpolation methods are compared and discussed. (20 refs.)

110177 Measurement of potential alpha energy concentration of radon and thoron daughters using an electret dosemeter. P.Kotrappa, S.K.Dua, P.C.Gupta, N.S.Pimpale, A.H.Khan (Health Phys. Div., Bhabha Atomic Res. Centre, Bombay, India).
Radiat. Prot. Dosim. (GB), vol.5, no.1, p.49-56 (1983).
An electret dosemeter consisting of an electret loaded into a 60 ml chamber was modified to hold an air sampling filter paper at the bottom and air was sampled through it. It was shown that nearly 20% of the energy of alpha radiation emitting from the filter paper was dissipated in the volume of the chamber. This energy in turn produced ion pairs which were collected by the electret resulting in a measurable change in charge status of the electret. By taking an air sample of known volume and allowing the registration of alpha energy, not only during sampling but also for three hours after sampling, a direct measure of the potential alpha energy concentration of radon daughters could be calculated in easily interpretable working level units. By proper choice of the thickness of the electret and the total flow, it was possible to measure radon daughter concentations down to milliworking level units. For thoron decay products, it was shown that the alpha energy concentration measured during sampling and up to a period of 7.7 hours post sampling, time being reckoned from the mid-time of sampling, yielded 33% of the potential alpha energy concentration due to thoron daughters. (9 refs.)

110178 Annealing and fading properties of CaF_2:Tm (TLD-300). C.Furetta, Yi-Kang Lee (Inst. of Nuclear Sci., Nat. Tsing Hua Unv., Hsinchu, Taiwan).
Radiat. Prot. Dosim. (GB), vol.5, no.1, p.57-63 (1983).
The annealing and fading characteristics of CaF_2.Tm have been investigated. The best annealing temperature and time are given. The thermal treatment after exposure and before read out has also been studied. This work also reports the results of studies on fading in dark and light conditions. The stability of well separated glow-peaks was studied and is discussed. (7 refs.)

110179 Some characteristics of neutron field and kerma distributions inside a phantom irradiated at a cyclotron. B.Dorschel, G.Streubel (Phys. Dept., Tech. Univ. Dresden, Dresden, Germany).
Radiat. Prot. Dosim. (GB), vol.5, no.1, p.65-70 (1983).
Neutron spectra at the surface and at different depths within a bodylike phantom calculated by the Monte Carlo method are compared with measured spectra. Furthermore, derived fluence and kerma values obtained by integrating the calculated spectra are compared with measured results from track detectors and ionisation chambers. The results demonstrate the applicability of calculation methods for the purpose of radiation protection in neutron fields. (11 refs.)

110180 The low-dose controversy and radiological risk assessment. P.Hubert (CEPN, Fontenay-aux-Roses, France).
Health Phys. (GB), vol.45, no.1, p.144-9 (July 1983).
Identifies the choices and parameters required when elaborating a dose effect relationship and that are important from a practical point of view. The sensitivity of these factors is analysed. Although many figures still rely on BEIR III assumptions and on T 65 dosimetry, the conclusions, primarily methodological in character, should have more general implications. (10 refs.)

110181 Assessment of radiation dose to infants from breast milk following the administration of ^{99m}Tc pertechnetate to nursing mothers. O.T.Ogunleye (Coll. of Medicine, Univ. of Lagos, Lagos, Nigeria).
Health Phys. (GB), vol.45, no.1, p.149-51 (July 1983).
The results of measurements of ^{99m}Tc activity in the milk samples from 2 patients are presented. It was found that, though the concentration in milk after 24 hr from both patients was insignificant, there were some variations in the initial levels of activity in the samples. The maximum concentration was found around 2 hr after injection. This initial level variation may not be unconnected with the functional status of the patients' thyroid since early uptake of technetium pertechnetate by the thyroid has been utilized to determine its status. Thus, a relatively high thyroid uptake in the early hours would reflect in a low concentration in the breast milk. The total body dose a child would have received if feeding had commenced at the times indicated and child was taking 150 ml milk per meal is shown. The child would have accumulated a whole body dose varying from 684.7-0.5 mrad. In addition, the child is exposed to external radiation from the mother delivering a whole-body dose of the same order of magnitude. The dose to the child's thyroid will be about 13.7-0.01 rad. The author feels that it is advisable to instruct nursing mothers to abstain from breast-feeding for at least 24 hr following the administration of up to 1.5 mCi technetium pertechnetate. (8 refs.)

110182 Response of an area albedo neutron dosimeter. V.P.Gupta (EG & G Idaho Inc., Idaho Falls, ID, USA).
Health Phys. (GB), vol.45, no.1, p.158-62 (July 1983).
An area albedo neutron dosimeter (AAND) is described. This AAND is presently used at the Idaho National Engineering Laboratory (INEL) and the Bendix Field Engineering Corporation at Grand Junction, CO. The response of the AAND to different neutron spectra is examined when it is exposed free in air or against concrete block walls. (3 refs.)

110183 Measurements of dose from secondary radiation outside a treatment field. K.R.Kase, G.K.Svensson, A.B.Wolbarst, M.A.Marks (Dept. of Radiation Therapy, Harvard Medical School, Boston, MA, USA).
Int. J. Radiat. Oncology Biol. Phys. (GB), vol.9, no.8, p.1177-83 (Aug. 1983).
Radiation dose to organs outside the radiotherapy treatment field can be significant and therefore is of clinical interest. The authors have made measurements of dose at distances up to 70 cm from the central axes of 5×5, 15×15 and 25×25 cm radiation fields of 300 kVp, 4 MV and 8 MV X-rays,

and ^{60}Co gamma rays, at the surface and at depths in water of 5 and 10 cm. Contributions to the total secondary radiation dose from water scatter, machine (collimator) scatter and leakage radiation have been separated. The authors have found that the component of dose from water scatter can be described by a simple exponential function of distance from the central axis of the radiation field for all energies and field sizes. Machine scatter contributes 20 to 40% of the total secondary dose depending on machine, field size and distance from the field. Leakage radiation contributes very little dose, but becomes the dominant component at distances beyond 60 cm from the central axis. Estimates of the risk of second tumors in long term survivors indicate a small incremental increase above the natural incidence rate based on information from the 1980 BEIR Committee report. (8 refs.)

110184 Dosimetry of the Siemens Mevatron 67 linear accelerator. J.L.Horton (Dept. of Radiation Therapy, Cleveland Clinic Foundation, Cleveland, OH, USA).
Int. J. Radiat. Oncology Biol. Phys. (GB), vol.9, no.8, p.1217-23 (Aug. 1983).
Measurements have been made on a Siemens Mevatron 67 linear accelerator. The change of beam quality has been measured as a function of position off-axis and compared to another Siemens 6 MV linear accelerator. Similarly beam profiles are compared to a Siemens Mevatron VI. Additional measurements include entrance dose, inverse square applicability, central axis percent depth dose, tissue-maximum ratios, output factors, wedge factors and block transmission factors. Comparison is made with an Atomic Energy of Canada Limited Therac 6 and Varian Clinac 6-100. (15 refs.)

110185 Neutron and γ-ray absorbed dose measurements for the d-Be reaction at low incident deuteron energies. R.L.Maughan, M.J.Roper (Cancer Res. Campaign Gray Lab., Mount Vernon Hospital, Northwood, England).
Phys. Med. & Biol. (GB), vol.28, no.1, p.51-6 (Jan. 1983). [received: Sept. 1983]
Measurements have been made using a tissue-equivalent A-150 ionisation chamber and a neutron insensitive Geiger-Muller tube in order to determine separately the neutron and γ-ray absorbed doses for deuteron energies, E_d, in the range 1.5-4.0 MeV. The authors conclude that the d-Be reaction provides a useful neutron source for radiobiological experiments at incident deuteron energies between 2 and 10 MeV. At energies below 2-2.5 MeV and with beam currents between 0.5 and 1 mA the neutron absorbed dose rate drops sharply and the γ-ray contamination increases appreciably. (16 refs.)

110186 Monte Carlo evaluation of the Sievert integral for brachytherapy dosimetry. J.F.Williamson (Dept. of Therapeutic Radiology, Univ. of Minnesota Hospitals, Minneapolis, MN, USA), R.L.Morin, F.M.Khan.
Phys. Med. & Biol. (GB), vol.28, no.9, p.1021-32 (Sept. 1983).
The Sievert integral, widely used to compute dose distributions about filtered line sources, assumes that the emitted energy fluence if exponentially attenuated by the filter thickness traversed by the primary photons. To evaluate this approximation, a Monte Carlo simulation was performed realistically modelling the diffusion and energy degradation of primary photons due to coherent, incoherent and photoelectric interactions in the source filter. Estimates of the exposure rate at points near the source were obtained using analytical averaging. Comparison of the two models shows that for ^{226}Ra and ^{192}Ir sources, the Sievert algorithm consistently overestimates the exposure rate per unit activity. However, such errors may be significantly reduced if source intensity is expressed in terms of exposure rate. Computed exposure rate distributions based on exposure rate calibrations are also less sensitive to uncertainties in available spectroscopic data. (22 refs.)

110187 Microdosimetric properties of alpha-particle tracks measured in a low-pressure cloud chamber. T.Budd (Environmental & Medical Sci. Div., AERE Harwell, England), C.S.Kwok, M.Marshall, S.Lythe.
Radiat. Res. (USA), vol.95, no.2, p.217-30 (Aug. 1983).
A cloud chamber which can make visible individual ions in the tracks of α-particles is available at Harwell. Work on the theory of droplet formation and growth has enabled a tissue-equivalent gas of lower density than previously possible to be used in the chamber. This has enabled even the closest ions in α-particle tracks to be individually resolved. Extensive spatial analysis has been carried out on α-particle track segments at 5.0, 3.4, and 1.1 MeV. Radial distributions of ionization density with distance from the track have been derived. Rossi 'Y' distributions have been calculated for target sizes of 10 and 50 nm (at 100 kg m^{-3}) and, finally, interdroplet distance distributions have been derived. These results may be compared to Monte Carlo calculations of track structure and may also provide useful data for theories of radiation damage. (8 refs.)

(inc. radiation monitoring)

110188 Sterilization of TLD finger monitors. R.W.Pollock (Siemens Gammasonics Inc., Des Plaines, IL, USA), P.C.Philip, S.Jayaraman.
Health Phys. (GB), vol.45, no.1, p.157-8 (July 1983).
It is important to measure extremity dose during surgical procedures such as heart catheterizations, yet many doctors are hesitant to wear an unsterilized monitoring device. This note describes work on the effect of sterilization on lithium fluoride thermoluminescent dosimeters which has been shown that a cold, chemical method may be satisfactorily used. It is concluded that cold sterilization with ethylene oxide does not appear to have a significant effect on the response of TLD finger monitors, even when the rings are repeatedly sterilized. The authors hope that these results will induce more medical personnel to monitor their extremity exposures during surgical procedures. (no refs.)

110189 Monitoring of ^{125}I in saliva of workers internally contaminated with ^{125}I. K.Nishizawa, N.Hamada, S.Sakuma (School of Medicine, Nagoya Univ., Nagoya-shi, Japan).
Radioisotopes (Japan), vol.32, no.8, p.364-71 (Aug. 1983).
Monitoring of workers who did iodination of protein was performed for 5 months on 10 persons. The activity in saliva was evaluated by the sum peak method and by using a NaI(Tl) detector and a 400-channel analyzer. The concentration of ^{125}I in saliva ranged from 4.65±2.1 cBq/ml to 135±2.7 cBq/ml and the average was 20.8±1.9 cBq/ml. The ratio of concentration in saliva to used activity ranged $(2.2\pm0.64)\times10^{-9}$ to $(3.6\pm0.073)\times10^{-8}$ and the average was $(8.1\pm1.1)\times10^{-9}$. The thyroidal uptake per iodination ranged 146 Bq to 2700 Bq. The ratio of the uptake to the used activity ranged from 7.3×10^{-5} to 5.4×10^{-6}. The thyroidal absorbed dose ranged from 378 μGy to 4740 μGy. Monitoring of ^{125}I in saliva was proved to be a useful method for investigating the internal contamination of workers doing iodination. (15 refs.)

110190 Measurement and shielding of the secondary radiation from betatrons. S.Cuzino, D.Catana, I.Panaitescu (Inst. Central de Fizica, Inst. de Fizica si Tehnologia. Aparatelor cu Radiatii, Bucuresti-Magurele, Rumania).
Stud. & Cercet. Fiz. (Rumania), vol.35, no.6, p.519-26 (1983). In Rumanian.
Secondary radiation is generated by leakage and/or scattering outside the useful primary beam of an accelerator. Its measurement is necessary for each accelerator, first of all for the calculation of biological protection barriers. Owing to the high energy of the bremsstrahlung these measurements raise specific problems and have to be carried out by means of cavity ion chambers with convertor caps of suitable material and thickness. Measurements carried out on two 15 MeV nondestructive testing betatrons concerning their secondary radiation are reported. Results show that, when local shielding is provided on the radiation source, the secondary radiation is everywhere less than 1% of the primary beam. A secondary maximum is manifest, generated by a spurious target. The calculation of the protection barriers for the secondary radiation and their subsequent testing through measurements are discussed. (12 refs.)

110191 Radon and thoron in buildings. G.C.Meggitt (UKAEA, Culcheth, England).
Radiat. Prot. Dosim. (GB), vol.5, no.1, p.5-17 (1983).
The physical factors determining the levels of radon and thoron in buildings are reviewed, including the sources, the ventilation rate and the natural aerosol concentration. The health risks are summarised and the significance for actinide-in-air monitoring is discussed. (40 refs.)

110192 Deep-ocean radioactive waste disposal: an evaluation of the seaweed critical pathway. M.S.Baxter (Dept. of Chem., Univ. of Glasgow, Glasgow, Scotland), S.R.Aston.
Health Phys. (GB), vol.45, no.1, p.139-44 (July 1983).
Develops upon a recent (1980) review by the Nuclear Energy Agency of the Organisation of Economic Cooperation and Development in which the critical pathways for public exposure to radioactivity released to the marine environment are defined for each of the major nuclides in solid nuclear wastes. Conservative conclusions are drawn, namely that deep-sea disposal of all high-activity wastes accumulated by 2000 AD could conceivably produce a significant and excessive hazard to man via the seaweed consumption pathway. The major risk would be associated with ^{224}Cm and Am isotopes. (16 refs.)

110193 ^{137}Cs deposition in Japanese temporary residents of England. M.Togo, I.Anzai (Dept. of Radiological Health, Univ. of Tokyo, Tokyo, Japan), T.Togo.
Health Phys. (GB), vol.45, no.1, p.162-6 (July 1983).
The subjects of the study reported were five siblings in a family and their father. It is shown that: (1) deposited ^{137}Cs in the Japanese who temporarily resided in England was most likely to have come through fish from the North Sea, being slightly polluted with the nuclide discharged from Sellafield, and (2) the ^{137}Cs deposited in England decreased after return to Japan, in spite of increased fish, shellfish and seaweed consumption, which are only contaminated with ^{137}Cs from weapon tests' fallout. 87.65 AEROSPACE BIOPHYSICS AND MEDICAL PHYSICS (EFFECTS OF ACCELERATIONS, WEIGHTLESSNESS AND ENVIRONMENT)

(see also 94.80 Aerospace facilities and techniques; space research)

110194 Prospects of autotrophic link functioning in biological life-support systems based on cell biology studies. E.L.Kordyum, E.M.Nedukha, A.F.Popova, P.G.Sidorenko, V.M.Fomicheva, K.M.Sytnik (N.G. Kholodny Inst. of Botany, Acad. of Sci., Kiev, Ukrainian SSR).
Acta Astronaut. (GB), vol.10, no.4, p.225-8 (April 1983).
On the basis of using modern methods of cytological analysis, growth peculiarities, reproduction and structure of plant cells of different levels of organisation (unicellular algae, mosses, angiosperms, cell cultures of higher plants) were investigated in response to the following factors—weightlessness, hypogravity, magnetic fields of various intensity, vibration and acceleration. It was shown that many discovered biological effects of space flight are connected with the degree of complexity of the object organisation and are intensified with increasing duration of flight. (7 refs.)

110195 Proceedings of Workshops III and IV and of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission F (Meeting F2) of the COSPAR Twenty-Fourth Plenary Meeting.
Adv. Space Res. (GB), vol.3, no.8 (1983).
Conference held at: Ottawa, Canada. Date 16 May-2 June 1982. Sponsors: COSPAR. The following topics were dealt with: biological quarantine procedures for spacecraft, extreme environments such as Mars and Antarctica, radiation effects on bacteria, plants, seeds and insects, and finally the biological hazards of radioactivity and radiation to man and other mammals.

110196 Proceedings of Workshop VII and of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission F (Meetings F1 and F4) of the COSPAR Twenty-Fourth Plenary Meeting.
Adv. Space Res. (GB), vol.3, no.9 (1983).
Conference held at: Ottawa, Canada. Date 16 May-2 June 1982. Sponsors: COSPAR. The following topics were dealt with. Amino acids in meteorites, chemistry and molecules in interstellar space, prebiotic biochemistry on the primitive Earth, prebiotic molecular biophysics, extraterrestrial intelligent life and very low gravity biological experiments on animals and plants.

110197 Life science research on-board Spacelab. II. European multipurpose experimental facilities. M.J.F.Fowler (Dept. of Physiology, Royal Free Hospital School of Medicine, London, England).
J. Br. Interplanet. Soc. (GB), vol.36, no.8, p.345-50 (Aug. 1983).
For pt.I see ibid., vol.36, no.6, p.243-8 (1983). To facilitate life science studies on board Spacelab, a number of multipurpose experimental facilities are under development by the European Space Agency (ESA). These include: (1) the Biorack for biological investigations on plants, tissues, cells, bacteria and insects; (2) the Space Sled for vestibular (balance) studies; (3) the Anthrorack for advanced human physiology experiments; and (4) Eureca, a retrievable carrier, for botanical and protein crystallisation studies of up to six months' duration. These facilities are briefly described together with a chronology of the planned flights. (12 refs.)

110198 A systems approach to the physiology of weightlessness. R.J.White, J.I.Leonard (Management & Tech. Services Co., Houston, TX, USA), J.A.Rummel, C.S.Leach.
Proceedings of the Fifteenth Hawaii International Conference on System Sciences 1982, Honolulu, HI, USA, 6-8 Jan. 1982 (HI, USA: Hawaii Int. Conference Syst. Sci. 1982), p.264-73 vol.2
This paper presents a systems approach to the unraveling of the complex response pattern of the human subjected to the challenge of weightlessness. The major goal of this research is to obtain an understanding of the role that each of the major components of the human system plays following the transition to and from space. The cornerstone of this approach is the utilization of a variety of mathematical models in order to pose and test alternative hypotheses concerned with the adaptation process. An integrated hypothesis for the human physiological response to weightlessness is developed. (24 refs.)

110199 Somatic embryogenesis in anise (Pimpinella anisum L.) cell cultures in microgravity environment. R.A.Kudielka, R.R.Theimer (Botanisches Inst., Univ. Munchen, Munchen, Germany).
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.63-8
Dedifferentiated cultures of anise will be sent into orbit in Spacelab (SL) during its D1-mission. Every 24 hr aliquots will be tranferred to embryogenic growth medium under microgravity conditions to induce somatic embryogenesis. During the 7 day period of the SL-D1-mission the cell aggregates will differentiate into torpedo-shaped embryoids via globular and heart-shaped embryo forms. After return, embryoids in each stage of differentiation will be recovered and intact anise plants will be regenerated. These and part of the embryoids will be examined using morphological, biochemical and physiological methods. The data will be compared to those obtained with plant material differentiated under simulated SL conditions in a 1 g environment on Earth. The experiments should yield important data on the effect of gravity on embryogenesis and differentiation in higher plants. (12 refs.)

110200 The influence of near weightlessness conditions on the development of the vertebrate gravity sensing system—Statex experiment Spacelab Mission D1. J.Nuebert, W.Briegleb, A.Schatz (Inst. for Aerospace Medicine, Cologne, Germany).
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.69-74
The goal of the Frog Statolith Experiment of the Spacelab Mission D1 is to study the effect of near weightlessness on different development stages of embryos and tadpoles. The results will be compared with those of weightlessness simulation experiments. Looking forward to long duration manned spaceflight onboard space stations, investigations of the interaction between gravity sensing system function and development and near weightlessness becomes very important. Despite many studies in diverse organisms knowledge of these phenomena is incomplete. One sector of investigation should be the analysis of possible morphologic alterations in the gravity sensing system in vertebrates influenced by near weightlessness conditions. Morphology and function of this system is similar in principle in vertebrate classes including man. (7 refs.)

110201 Effects of microgravity on the mechanisms for genetic recombination. O.Ciferri, M.Sosio, A.M.Orlandoni, O.Tiboni, P.G.Mazza (Dept. of Genetics & Microbiology, Univ. of Pavia, Pavia, Italy).
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.75-6
The effect(s) of microgravity on genetic recombination, that is, the transfer of DNA from cell to cell, will be investigated (in a space experiment) in bacterial cells undergoing conjugation, transduction, or transformation. These fundamental processes involve primarily the activity of the cell membrane and concern the interactions cell/cell, cell/bacteriophage, and cell/DNA, respectively. (2 refs.)

110202 The role of gravity in the establishment of the dorso-ventral axis in the developing amphibian embryo. G.A.Ubbels, T.G.Brom, H.P.Willemsen, J.J.H.van Nunen (Hubrecht Lab., Utrecht, Netherlands).
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.77-82
The establishment of polarities in early embryogenesis is essential for normal development. Centrifugation experiments in Xenopus laevis eggs have shown that gravitationally induced rearrangements of the yolk predictably determine the orientation of the dorso-ventral axis of the embryo, regardless of the original position of the sperm entry point or the grey crescent. This suggests a role of gravitation in the determination of bilateral symmetry. That assumption will be tested in a microgravity experiment (A08/52NL) in Biorack in the Space Shuttle. Preparatory experiments and the development of an automatic experiment container for fertilization and fixation of Xenopus eggs are described. (27 refs.)

110203 The possible involvement of gravitational forces in the topological distribution of cytoplasmic determinants in Drosophila melanogaster embryos. R.Marco, I.Vernos, M.Cervera, A.Domingo (Inst. de Enzimologia y Patologia Molecular, Univ. Autonoma de Madrid, Madrid, Spain).
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.83-7
The hypothesis tested in the proposed space experiment described is the possible involvement of gravitational forces in the shaping of the topological distribution of the maternal information in the early embryo. In earlier space flights, both American and Russian, it has been observed, in Drosophila and other insects, that developmentally abnormal animals have appeared during or immediately after the space flight. The objective of this proposed experiment is to test in a controlled way whether the appearance of these abnormalities correlate with the microgravity conditions during oogenesis. The proposed protocol makes possible a detailed study of the presumptive subcellular and molecular mechanisms affected by the microgravity or other parameters of the space flight environment. (22 refs.)

110204 Biorack experiment A08/19 D: dosimetric mapping inside Biorack. H.Bucker (Deutsche Forschungs- und Versuchsanstalt fur Luft- und Raumfahrt eV, Cologne, Germany), O.C.Allkofer, R.Beaujean, W.Enge, R.Facius, H.Francois, W.Heinrich, G.Horneck, R.Pfohl, G.Portal, G.Reitz, M.Schafer, E.Schopper, J.-U.Schott.
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.89-91
The experiment described will document the radiation environment inside Biorack. These experimental data will be compared with those of other spaceflights and with theoretical predictions. It will provide radiation baseline data for the other Biorack experiments. For this purpose, 6 type I containers housing stacks of different kinds of radiation detectors (cellulose nitrate, lexan, CR 39, nuclear emulsions, AgCl, and LiF-thermoluminescence dosimeters) will be accommodated in the incubators of Biorack. The analysis of the dosimeters will be performed by the Biostack research team. (10 refs.)

110205 Experiment A08/18 D on Biorack: embryogenesis and organogenesis of Carausius morosus under spaceflight conditions.. H.Bucker (Deutsche Forschungs- und Versuchsanstalt fur Luft- und Raumfahrt eV, Cologne, Germany), H.Francois, E.H.Graul, W.Heinrich, H.Hoffken, G.Horneck, G.Reitz, W.Ruther, R.Pfohl, G.Portal, E.Schopper, J.-U.Schott.
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.93-6
The influence of space flight environment, especially HZE particles of cosmic radiation and microgravity, on embryogenesis and organogenesis of insects will be studied in Carausius morosus eggs. Five different stages of development will be used, which differ in radiation sensitivity and regenerative capacity. The eggs, in monolayers, will be sandwiched between visual track detectors. The results will give information on: the effectiveness of heavy ions of cosmic radiation on developmental processes in insects; potential disturbances of differentiation processes by microgravity; potential combined effects of radiation and microgravity. (9 refs.)

110206 The clinostat—a tool for analysing the influence of acceleration on solid-liquid systems. W.Briegleb (Inst. for Aerospace Medicine, Deutsche Forschungs- und Versuchsanstalt fur Luft- und Raumfahrt eV, Cologne, Germany).
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.97-101
The (fast) clinostat is a platform which rotates about an horizontal axis. Near the center of rotation is mounted a stiff, closed cuvette filled with a liquid suspension of particles. Depending on the density difference between the particles and the liquid, and on the viscosity of the liquid, particles may settle within circular trails. These circular trails become points if the speed of rotation of the clinostat increases (fast clinostat); the particles become motionless in respect to gravity. Instead of gravity centrifugal forces become effective. But within microscopic dimensions the influence of the centrifugal force on particles even with a density difference to the liquid of 1 g cm^{-3} and 2 μm in diameter can be balanced by Brownian movement. Thus for typical cell systems the degree of zero g simulation is 100%. From experiments with different cell systems on special clinostats the author has obtained indications for regulatory reactions of different cell parameters during zero g simulation. (18 refs.)

110207 Problems of 0-g simulation with the fast-running clinostat (for cellular study). A.Schatz (Inst. for Aerospace Medicine, Deusche Forschungs- und Versuchsanstalt fur Luft- und Raumfahrt eV, Cologne, Germany).
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.103-5
The theoretical background of the 0 g simulation technique with the fast-running clinostat is presented together with the important parameters and limitations on biological systems for selection. Specific attention is paid to the interaction with the Earth's magnetic field which might introduce effects in addition to those of μ.g. (9 refs.)

110208 The use of horizontal clinostats in plant physiology. W.Hensel (Botanical Inst., Univ. of Bonn, Bonn, Germany).
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.107-8
Slow rotating clinostats (e.g. 2 rpm) are common tools in experiments on gravitropism. But, if normal grown roots are subjected to clinostat rotation for 20 h, ultrastructural response of statocytes, delay in graviresponse, increase in ethylene production and shortening of the cycle time of root meristem are caused. These effects can be avoided if plants develop on the clinostat from the onset of soaking of the seeds. Only under these specific conditions do clinostats simulate physiological zero-g and can be used in experiments on gravitropism without too many restrictions. (8 refs.)

110209 Influence of gravity on cell growth and migration. A.Tschopp, A.Cogoli (Lab. fur Biochem., Eidgenossische Tech. Hochschule Zurich, Zurich, Switzerland).
Space Biology with Emphasis on Cell & Developmental Biology Proceedings of a Workshop (ESA SP-206), Cologne, Germany, 9-11 March 1983 (Noordwijk, Netherlands: ESA 1983), p.109-14
When HeLa cells, chicken embryo fibroblasts, sarcoma Galliera cells, Friend leukemia virus transformed cells and human lymphocytes are cultured in a hypergravitational field (e.g. 10×g) growth rate is increased by 20-30%, whereas glucose consumption per cell is lower than at 1×g. Tracking of cell movements on gold-coated substrates reveals that cell migration is hindered at high-g. These findings suggest that under gravitational stress the cell is either capable of shifting to other metabolic pathways and/or consumes less energy at high-g than 1×g. The authors describe ground-based investigations related to experiments to be performed on future SPACELAB missions. (33 refs.)

87.70 BIOMEDICAL ENGINEERING

110210 An instrument for measuring small flows during biliary tract surgery. P.Baxa (Istituti di Geodesia e Geofisica, Univ. of Trieste, Trieste, Italy), G.Alberi, M.Cherubini, G.Poiani.
Clin. Phys. & Physiol. Meas. (GB), vol.4, no.3, p.333-7 (Aug. 1983).
Presents the components of an instrument able to measure low flows and describes the physical principles on which the instrument is based. The main features of this instrument are: (i) it is simple, compact and easy to handle; (ii) it avoids any contact between the electronic circuit and the saline solution; (iii) it allows continuous flow measurement; and (iv) it has an analogue output, which is recorded graphically. This graphic record of the measurement can be used later to give information on the volume of the biliary tract and on its elastic properties. It is possible to change the scale of this instrument simply by substituting a different narrow section of the main tube; the sensitivity of the instrument is increased for lower values of the cross-section. (6 refs.)

110211 Efficient, inexpensive rapid cuff inflator for venous occlusion plethysmography. A.C.M.Chu, D.St. Andrew (Dept. of Medical Phys., Univ. Coll. Hospital, London, England).
Clin. Phys. & Physiol. Meas. (GB), vol.4, no.3, p.339-41 (Aug. 1983).
The cuff inflator design described has been found to be adequate for clinical purposes. It has a cuff inflation time of less than 0.3 s. It is safe to use as prolonged overpressurisation cannot happen. It is economical to produce, and is sufficiently compact to be mounted on a trolley side by side with the plethysmographic equipment to form a mobile unit, enabling venous occlusion plethysmography to be performed at any location. (no refs.)

110212 A technique for the measurement of 'sucking' in bottle fed infants. T.Drake (Dept. of Linguistics, Univ. of Sheffield, Sheffield, England), A.J.Wilson.
Clin. Phys. & Physiol. Meas. (GB), vol.4, no.3, p.343-5 (Aug. 1983).
Describes a technique for measuring the 'sucking' pressures of bottle-fed infants. The system is based on standard feeding bottle components and therefore the regime used during a study can closely resemble the regime that is used for 'normal' feeding. The system provides a semi-quantitative way of assessing the sucking process which can be used to assess the efficacy of the oral prosthesis and special teats that are currently available for infants with cleft palates. In addition to this, such a system could prove useful in evaluating new prostheses and new specialist teats as they are developed, since there is currently no objective method of assessment. (1 ref.)

110213 Four-dimensional processing and display system for cardiovascular data. S.E.Wixson (Clinical Cardiology Computer Centre, Univ. of Alabama, University Station, Birmingham, AL, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.140-5 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A four-dimensional image refers to a time (or other) series of three-dimensional images. The system consists of components to develop, test and run programs and to manipulate and store multidimensional digital images. A four-dimensional display is used to study raw and processed data. The display uses binocular stereo to generate a three-dimensional image and bulk memory to store multiple stereo pairs for the fourth dimension. Voice input and output will be used to communicate with the system. A binocular infrared eye tracker will be used as a multidimensional cursor to interact with the data. Software development areas are summarised. (no refs.)

110214 Biostereometric data processing in ERGODATA: choice of human body models. J.C.Pineau, R.Mollard, M.Sauvignon, M.Amphoux (Lab. d'Anthropologie Appliquee, Univ. Rene Descartes, Paris, France).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.169-71 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
The definition of human body models was elaborated with anthropometric data from ERGODATA. The first model reduces the human body into a series of points and lines. The second model is well adapted to represent volumes of each segmentary element. The third is an original model built from the conventional anatomical points. Each segment is defined in space by a triangular plane located with its 3-D coordinates. This new model can answer all the processing possibilities in the field of computer-aided design (CAD) in ergonomy and also biomechanics and orthopaedics. (no refs.)

110215 Visual and spectral EEG analysis in the evaluation of the outcome in patients with ischemic brain infarction. K.Sainio (Dept. of Pediatrics, Univ. of Helsinki, Helsinki, Finland), D.Stenberg, I.Keskimaki, A.Muuronen, M.Kaste.
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.117-24 (Aug. 1983).
Serial EEGs were recorded in 15 patients with acute cerebral infarctions in order to study clinical and prognostic correlations. The EEG was recorded within 48 h from the first symptoms and thereafter weekly for 4 weeks. The EEGs were analyzed both visually and with a computerized spectral analysis. Eight of the patients recovered fully and seven had permanent neurological deficits. On admission, 87% of the patients had an abnormal EEG by visual analysis. The spectral parameters correlated well with visual findings, especially the delta and alpha bands. The spectral analysis was superior to visual in predicting the correct laterality of the lesion. It showed the correct side of the lesion in 87%, while the visual did it in only 54% of the cases. The first EEG records reliably predicted the outcome of the patients. The degree of background abnormality was most important in visual EEG analysis. In spectral analysis, parameters from single derivations were superior to the average of all derivations. A high proportion of delta or low proportion of alpha power were reliable indicators of poor outcome. (16 refs.)

110216 Improved telemetric EEG monitoring in epileptic patients. A.Kamp, J.W.Aitink (Inst. of Medical Phys. TNO, Utrecht, Netherlands).
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.254-5 (Aug. 1983).
Describes a 20-channel EEG telemetry system which provides EEG monitoring with standard EEG recording performance for use in epileptic patients. The EEG activities of 20 electrodes are separately amplified and transmitted employing PCM cable telemetry. A standard EEG apparatus is used, allowing montages to be freely selected and changed during recording. (4 refs.)

110217 The use of strain gauges for biometrics in Europe. P.M.Calderale (Politecnico di Torino, Torino, Italy).
Eng. Med. (GB), vol.12, no.3, p.117-33 (July 1983).
Strain gauges have a relevant role in mechanical measurements, and it is therefore quite natural that they find widespread use in biomechanics. They are used for the evaluation of the strain and stress distribution in particular points of structures of biomechanical interest, and, moreover, for the validation of numerical analyses. This work reviews the use that European researchers make of this technique, mainly in orthopaedics, dentistry, and sport biomechanics. (63 refs.)

110218 Medical engineering: meetings on research priorities. E.A.Mason (Sci. & Engng. Res. Council, Swindon, England).
Eng. Med. (GB), vol.12, no.3, p.143-4 (July 1983).
The importance of 'workshop' type meetings to determine research priorities in a range of medical engineering topics has been demonstrated by means of a series of such meetings organised by the Science and Engineering Research Council. Four workshop-type meetings have been held in the past 2 years on topics ranging from incontinence to body access, and these have resulted in new, collaborative research programmes and an increase in the general level of interest in the topic. Further meetings of this type are planned in the coming twelve months. (4 refs.)

110219 Bioengineering at Durham University. A.Unsworth (Dept. of Engng., Univ. of Durham, Durham, England).
Eng. Med. (GB), vol.12, no.3, p.149-50 (July 1983).
Bioengineering at Durham University has its origins in the early years of the Department of Engineering. During the late 1960s, the main themes of the research were human joint lubrication and the mechanical properties of particular cartilage. These continue as major areas of interest, but the work of the Bioengineering Research Group has now expanded to include many more aspects of orthopaedic engineering as well as the application of biomechanics of the field of rehabilitation. Membership of the Research Group is drawn from a number of establishments, but principally from the Department of Engineering at the University of Durham, the Departments of Orthopaedic Surgery at Newcastle University and Sunderland General Hospital, Departments of Rheumatology and Rehabilitation at Middlesbrough General Hospital, and Dryburn Hospital in Durham. (14 refs.)

110220 Delineation of the QRS complex using the envelope of the e.c.g.. M.-E.Nygards, L.Sornmo (Dept. of Medical Informatics, Linkoping Univ., Linkoping, Sweden).
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.538-47 (Sept. 1983).
A new algorithm for QRS delineation has been developed. Based on the envelope of the e.c.g. signal a delineation function is defined, which yields a single positive pulse for each complex. From this function the onset and end of the QRS or, alternatively, a fiducial point is determined. To remove low-frequency components such as S-T abnormalities without distortion of the QRS complex a filter with time-varying characteristics is used. The accuracy of the method has been evaluated in a test set of different QRS complexes obtained from coronary care patients. For QRS onset, the standard deviation of the difference between automated and manual determination was 7 ms in normal beats and 14 ms in ectopic beats. With simulated noise added to each waveform an average dispersion of 7 ms was observed in the recognition of the QRS onset at a signal-to-noise ratio of 15 dB. The corresponding dispersion in the location of a fiducial point was 2 ms. Using simulated e.c.g. data, the stability of the method is demonstrated for transitions between different waveform morphologies. (18 refs.)

110221 Noninvasive automatic monitoring of instantaneous arterial blood pressure using the vascular unloading technique. K.Yamakoshi, A.Kamiya (Res. Inst. of Applied Electricity, Hokkaido Univ., Sapporo, Japan), H.Shimazu, H.Ito, T.Togawa.
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.557-65 (Sept. 1983).
For the noninvasive monitoring of the beat-to-beat systolic and diastolic pressure and pressure waveform in the human finger, a new automated instrument was designed. This measurement is based on a principle called the vascular unloading technique. Using a hydraulic servocontrol system, the vascular volume change caused by intra-arterial pressure change can be compensated by applying counter pressure to maintain a constant vascular volume in the unloaded state. In this state the controlled counterpressure instantaneously follows the intra-arterial pressure. In this instrument all the necessary procedures, such as the setting of the reference value for the servocontrol, control of the servogain, processing and displaying of the data on a recorder, were carried out automatically. The simultaneous comparison of data with direct measurements and a few examples of the indirect pressure recordings by this instrument are shown and the principles, operation and evaluation of this method are described. This instrument was shown to permit the noninvasive and accurate tracking of instantaneous arterial pressure and to perform acceptably over a wide range of arterial pressure. (16 refs.)

110222 Ensemble averaging of locomotor electromyographic patterns using interpolation. R.Shiavi, N.Green (Vanderbilt Univ. Medical Center, Nashville, TN, USA).
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.573-8 (Sept. 1983).
A technique for calculating the ensemble averages of locomotor electromyographic patterns is described. It combines standard linear envelope detection with LaGrange interpolation. The e.m.g. envelope in each stride is demarcated with times obtained from foot-contact patterns and the time base is altered to 256 points by interpolation. The time-normalised envelopes are then averaged together to form the ensemble average. (27 refs.)

110223 CARRES: system for monitoring cardio-respiratory rhythms and the acquisition of electrophysiological data from the infant, application to the study of sudden infant death syndrome. R.Bruckert, F.Perrin, J.Pernier (CEMI-INSERM, Bron, France), M.-J.Challamel, M.Revol.
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.636-43 (Sept. 1983). In French.
Describes a computer system for monitoring the cardiac and respiratory rhythms and for collecting electrophysiological data from the newborn child to study the sudden infant death syndrome. The system uses the minicomputer MINC 23. The acquisition of the signals from the transducers, the detection of characteristic events on these signals, the coding of these events and the storage of the coded information in a file on floppy disc allowing its processing offline are performed in real time. (10 refs.)

110224 Method of averaging and of recognition of biomedical signals. Z.M.Wojcik (Polish Akad., Nauk, Poland).
Rozpr. Electrotech. (Poland), vol.28, no.1-2, p.315-25 (1982). In Polish. [received: Aug. 1983]
The paper presents a method and an electronic system for automatic averaging of a sampled analog signal, as well as a method and electronic systems for the recognition of these averaged signals. The averaging consists in determining a weighted mean of the results of sampling at each measuring point of the signal under consideration, distributed symmetrically in relation to the point. Due to the weighting, the influence of neighboring values of the signal being measured decreases as the point grows more and more remote. The results of the averaging remain in accordance with the elementary condition of representing events. In the process of recognition the values of characteristic functions of growth, decrease and zero of the signal under consideration are investigated. The values of these functions make up the alphabet of a formal grammar. The features of the signal under consideration constitute a set of final symbols of the grammar, being a result of the set of productions of the grammar. A certain automation exists for this grammar. The results of recognition and of statistical analysis of the signals under consideration constitute the final states of the automation. Electronic systems determining the most elementary characteristics of the signals are presented. The method presented is described with the recognition of electrocardiograms as an example. (13 refs.)

110225 The basic principles for acquiring an amplified signal from the His bundle by statistical filtering. R.J.Ascoeta, R.M.Campero, D.M.Gil, G.Gimenez Lascano, A.del Valle Herrero, J.Navarro, F.Martinez Corvalan.
Rev. Telegr. Electron. (Argentina), vol.71, no.838, p.162-6 (March 1983). In Spanish.
The authors explain that the His-Purkinje system is a set of cells for the transmission of electrical signals. Originating in the auriculo-ventricular node these signals are propagated by the myocardium which controls the ventricular contraction. The section of the electrocardiagram indicating this contraction process is of great importance in clinical cardiology since a knowledge of the form and location of the electrical signal which passes through the His bundle facilitates the diagnosis and prognosis of heart diseases. The signal to be examined, obtained at the body surface, requires to be amplified in such a way that noise can be eliminated. This is achieved by averaging various cycles from the required section of the electrocardiogram. To explain in detail how this signal is obtained the authors discuss the signal characteristics and the inherent noise, the method of treating the analogue signal and the recording of the relevent part of the electrocardiogram, the triggering of the A/D converter, the averaging process, the final reconversion to the analogue signal, the recording of the signal and its evaluation. (8 refs.) *G.W.*

110226 Real time signal processing of the exercise electrocardiogram. A.T.Moser, R.Stickney, C.Sawyer, C.Orrestad, V.Bhargava (Quinton Instrument Co., Univ. of California, San Diego, CA, USA).
Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.461-4
A system is described intended for on-line use during exercise testing. Absolute spatial vector velocity (ASVV) is generated from an orthogonal lead set and used for QRS detection, estimate of QRS duration and waveform correlation. Signals are averaged for noise reduction and search is made for isoelectric level and QRS offset in the ASVV as a function of minimal activity. Results of testing QRS detection algorithms are given. (11 refs.)

110227 QT interval measurements of long-term ECG recordings. Application of an automatic Holter analysis system. G.Critelli (Istituto di Patologia Medica, Univ. di Napoli, Napoli, Italy), F.Marciano, M.Mazzarella, M.L.Migaux.
Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.481-4
A previously reported long-term ECG analysis system has been used to measure the QTc. Particular care has been given to the problem of accurate measurement of the end of T waves. The preliminary object of this investigation is the degree of correlation between the lengthening of the QTc and the appearance or the intensification of PVCs. However, a pilot study, conducted on 24th recordings of a group of 9 subjects with various pathology and 9 subjects with no evidence of pathology, has disclosed the existence of some correlation between heart rate and QTc, the latter being calculated with a well-known widely used formula due to Bazett. The effect of this correlation on QTc is relatively small and it is evident that it could be detected only through automatic and precise measurement of 24 h recordings. It can superpose and interfere with the original object of the investigation (relation between QTc and PVCs). The authors are therefore planning a further inquiry in order to assess: the limits of the formula used for QTc calculations; and the characteristics of the correlation in well defined groups of subjects distinct for age, sex, pathology. (3 refs.)

110228 Application of identification and linear filtering algorithms to the R-R interval measurements. F.Bartoli, G.Baselli, S.Cerutti (Dept. of Electronics, Politech. di Milano, Milano, Italy).
Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.485-8
The first results of a measurement procedure of heart rate variability (HRV) are presented by using algorithms of identification with autoregressive (AR) models applied to the tachograms of a series of cardiological patients during exercise tests with the Batch Least Squares method. The pole diagram on the complex plane is plotted for a comprehensive evaluation of the identification results. The power spectrum is also estimated following the criterion of Maximum Entropy Method (MEM), fulfilling efficient information means as regards the various mechanisms involved in the HRV control and their pathophysiology already studied in literature. Such a new approach is considered important to realize original ways of information storing and displaying based upon statements of rigorous theoretical aspects. The trend towards the implementation of new developmental and technological tools for automatic analysis of HRV is remarkable. (22 refs.)

110229 The importance of measuring couplet frequency in the ambulatory electrocardiogram: correlation with invasive electrophysiologic studies. A.H.Gradman, W.P.Batsford, D.V.Cicchetti, E.C.Rieur, L.Leon, A.M.Van-Zetta (Cardiology Section, Yale Univ. School of Medicine, New Haven, CT, USA).
Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.489-92
In order to determine the usefulness of quantitative couplet frequency analysis in the evaluation of ventricular vulnerability, ambulatory ECG recordings (mean duration 13.8 hrs) were obtained in 48 adult patients undergoing invasive electrophysiologic (EPS) studies. During EPS, nine were found to be completely non-inducible, 11 demonstrated intraventricular reentry, 19 had non-sustained and 9 had sustained ventricular tachycardia. The YALECG computer system was used to quantify PVC and couplet frequencies and calculate the repetition index (R = the ratio of couplets to PVCs). While all three of these quantitative arrhythmia parameters increased progressively with increasing degree of ventricular inducibility, both couplet frequency and R correlated better than did PVC frequency. In addition, it was found that couplet frequency and R could be used to identify patient subgroups with a high likelihood of exhibiting serious inducible arrhythmias during EPS. It is concluded that couplet frequency is an important quantitative arrhythmia parameter which may be derived from the ambulatory ECG using computer-based analysis techniques. (9 refs.)

110230 HIS-bundle electrogram interpretation system. I.Beinlich, G.Neumann, E.Nash, A.Schade (Cardiology Div., Univ. of Bonn, Bonn, Germany).
Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.509-12
Time consumption is one of the drawbacks of clinical electrophysiology studies. HIS—a microcomputer based interpretation system for electrophysiology studies—was developed to reduce analysis time and to provide a standardized documentation form. Each program obtains data from such studies as incremental atrial pacing, sinus node overdrive suppression or programmed atrial extrastimulation. HIS measures basic conduction intervals, plots graphs of typical function curves and calculates parameters such as SNRT, SACT or the different refractory periods. Two reports will automatically be generated. All data are stored on floppy disc and may be accessed for further data analysis, editing, summarizing or printing. Emphasis was placed on user guidance, program flexibility and customization capability. (7 refs.)

110231 Microcomputer system for electro-oculography. M.Keye, J.Attikiouzel (Dept. of Electrical & Electronic Engng., Univ. of Western Australia, Nedlands, Australia), J.L.Black.
Australas. Phys. & Eng. Sci. Med. (Australia), vol.6, no.2, p.82-7 (April-June 1983). [received: Aug. 1983]
The design of a microcomputer based data acquisition system for EOG applications is described. The system measures the absolute voltage excursion corresponding to a horizontal eye movement of a specific amplitude. Several parameters of eye motion are measured including saccadic velocity, eye movement latency and accuracy of fixation. Calibration, light stimulus, data acquisition and processing are performed automatically. A number of tests are performed for averaging purposes. Individual tests are displayed in real time and can be manually aborted to inhibit acquisition of bad data. The system incorporates a Z80 based microcomputer with terminal and dual double-density floppy disk drives. Data acquisition hardware is separated and modularized in a standard 19″ subrack assembly. The system is inexpensive and portable, which permits its use for diagnosis in areas other than large hospitals. Expansion for applications other than EOG can easily be implemented with the existing system. (1 ref.)

110232 ISFET, a chemical sensor: an ion-sensitive transistor developed at the TH Twente. D.Sjobbema.
Elektronica (Netherlands), vol.31, no.12, p.43-5 (17 June 1983). In Dutch.
In the biomedical field there is a need to monitor continuously the behaviour of certain physical and chemical quantities in the body of the patient (in vivo). The intensive study of microelectronic circuits applied to the measurement of such quantities as ion concentrations and enzyme activity has led to the development of the ion-sensitive field effect transistor (ISFET). The electrical characteristics of this implantable and hence extremely small biosensor are reviewed, and its use for ion concentration measurement is compared with conventional techniques. The ISFET can be mass-produced, and should thus be reasonably priced. Work is in hand to improve the quality of the ISFET pH sensor, and to widen the principle to the measurement of other chemical quantities. (no refs.) *D.J.B.*

110233 Detection of fluid entry into the urethra by electric impedance measurement: electric fluid bridge test. S.Plevnik, P.Vrtacnik (Inst. 'J Stefan', Univ. 'E Kardelj', Ljubljana, Yugoslavia), J.Janez.
Clin. Phys. & Physiol. Meas. (GB), vol.4, no.3, p.309-13 (Aug. 1983).
The electric impedance of urine is considerably lower than that of urothelium: thus electrodes placed in the uretha can be used to show when urine penetrates the uretha during urinary incontinence. This principle is presented as part of a possible diagnostic test of urethral incompetence. (9 refs.)

110234 Cardiac electrophysiological studies: computer analysis using a digitiser and interactive visual display unit. T.Cochrane (Dept. of Cardiology, St. Bartholomew's Hospital, London, England), A.W.Dunlop, A.W.Nathan, A.J.Camm.
Clin. Phys. & Physiol. Meas. (GB), vol.4, no.3, p.321-31 (Aug. 1983).
Recording of localised intracardiac electrical potentials provides useful and important information on conduction disease in man. Analysis of intracardiac recordings involves measurement of large numbers of timing intervals representing the sequence of activation of the various parts of the cardiac conduction system. The authors describe a semi-automatic computer based analysis system tailored to the specific requirements of cardiac electrophysiological measurement. A digitising tablet is used in conjunction with a visual display oriented data handling package to input data directly to computer memory for sorting and further analysis. Particular attention is paid to providing the user with a system that is simple to learn yet is robust and flexible in use. The computer software is written entirely in the high level FORTRAN language. It is modular in design and is therefore easily adapted for the changing needs of a research oriented department. (9 refs.)

110235 Three-dimensional anthropometric measurement. C.Gross, M.Neuwirth, J.Graham, J.Pugh (Div. of Bioengng., Dept. of Orthopaedics, Hospital for Joint Diseases Orthopaedic Inst., New York, NY, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.116-18 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Three techniques for anthropometric assessment have been outlined: (1) spinal lordosimetry; (2) tibial torsimetry; and (3) leg inertiomet. All three techniques utilise computerised point encoding techniques and a variety of data output and presentation modes. Repeatability and accuracy were both shown to be acceptable when compared to that produced by conventional radiographic techniques. In fact, the recent concern over radiation exposure during routine anthropometric and orthopaedic assessments originally prompted the development of these non-radiographic techniques. (4 refs.)

110236 Improvement of the detectability of simulated pathological tremour e.m.g.s. by means of demodulation and spectral analysis. H.L.Journee (Dept. of Neurosurgery, State Univ. Groningen, Groningen, Netherlands), J.van Manen.
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.587-90 (Sept. 1983).
In e.m.g.s. recorded from patients with pathological tremours, the tremour cannot often be recognised by visual inspection. Demodulation of tremour e.m.g.s. improves the detectability of the tremour, but the signal-to-noise ratio remains poor. In this study, demodulated artificially generated tremour e.m.g.s. and e.m.g.s. from a patient with a pathological tremour were subjected to digital spectral analysis. Power spectra, phase and coherence functions of the modulating and demodulated signals were calculated. The result is that the detectability is improved from a modulation depth of 60% in modulated noise to 2-4% after demodulation and spectral analysis. The results suggest a useful application of the demodulator and analysing software to tremour e.m.g.s. in clinical practice. (10 refs.)

110237 A high-speed computerized tomography image reconstruction using direct two-dimensional Fourier transform method. N.Niki, T.Mizutani, Y.Takahashi (Faculty of Engng., Tokushima Univ., Tokushima, Japan), T.Inouye.
Trans. Inst. Electron. & Commun. Eng. Jpn. Part D (Japan), vol.J66D, no.6, p.707-14 (June 1983). In Japanese.
A practical high-speed image reconstruction algorithm based on direct two-dimensional Fourier transform method is developed. It eliminates low image quality resulting from the previous direct two-dimensional Fourier transform method. The key point of the new algorithm is the elaborate interpolations of the coordinate transform in the Fourier domain. The program based on the new algorithm is developed and is compared with that based on the conventional filtered backprojection method. The result reveals that the processing time is only one tenth of the latter and the quality of the obtained images are almost the same. (11 refs.)

110238 True r.m.s. volt/ammeters for surgical diathermy measurements during an operation. S.Grimnes (Dept. of Biomedical Engng., Rikoshospitalet Oslo, Oslo, Norway).
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.654-6 (Sept. 1983).
The risk of skin burns and the disturbance of electromedical equipment by high frequency currents are two important problems linked with the use of surgical diathermy in the operating room. The risk of skin burns is related to the high frequency power and measuring instruments used must respond to the true r.m.s. value. The crest factor may be >10 and the peak potential several thousand volts. In contrast, the disturbance of electromedical equipment probably depends more on the peak value than the r.m.s. value. The author discusses measuring principles and voltmeter and ammeter design. (2 refs.)

87.70J Prosthetics and other practical applications

110239 Impact resistance of variously mounted ophthalmic lenses. J.M.Fields,Jr., W.Goldsmith (Dept. of Mech. Engng., Univ. of California, Berkeley, CA, USA).
Am. J. Optom. & Physiol. Opt. (USA), vol.60, no.8, p.725-38 (Aug. 1983).
An experimental investigation was conducted to determine the frangibility of ophthalmic glass lenses loaded by the impact of steel spheres with diameters ranging from 6.35 to 28.6 mm when dropped from heights up to 1.905 m. These lenses were supported either simply, by a ring similar to that used in US Food and Drug Administration (FDA) drop tests, or while inserted in three different commercially used frame configurations placed on a head form. Strains up to 4000 μ strain were recorded by gauges cemented to the lenses, and impact forces on the glass up to 10.2 kN were determined, with many lenses surviving. Plano lenses tested according to standards experienced peak values of 2300 μ strain. The maximum force transmitted to the head form at the nose piece was found to be 91 N as determined by embedded crystal transducers. A series of special tests on circular plano lenses inserted in specially constructed rings and a circular eyewire indicated that eyewire tension is not a significant factor in impact resistance of lenses under both static and dynamic loading. (13 refs.)

110240 Hearing aids. R.Maas, R.Beck.
Acta Medicotech. (Germany), vol.30, no.6, p.207-13 (Dec. 1982). In German.
For 70 years hearing aids have been developed to enormous technical perfection. The development of these aids is, of course, a long process, and many technical parameters, as well as wishes and needs of patients, have to be considered. For a variety of forms of ear defects there is also a variety of different hearing aids. (no refs.)

110241 A study of antero-posterior load transfer in total hip replacement using a modelling technique. A.W.Miles, D.M.Dall, M.Rivarola (Univ. of Cape Town, Cape Town, S Africa).
Eng. Med. (GB), vol.12, no.3, p.113-15 (July 1983).
Describes the application of a modelling technique to determine the effect of the antero-posterior loading in the hip joint on bone and prosthesis stresses. The technique employs the use of model femora cast in a polyurethane foam and femoral prostheses made from various plastics to simulate titanium and chrome-cobalt. The study showed that antero-posterior forces produce significant stresses in the prostheses and emphasises the importance of considering these forces in the design of femoral prostheses. (3 refs.)

110242 A new approach to the fixation of a metacarpophalangeal joint prosthesis. P.S.Walker (Orthopaedic Biomech., Brigham & Women's Hospital, Boston, MA, USA), D.Nunamaker, R.Huiskes, T.Parchinski, D.Greene.
Eng. Med. (GB), vol.12, no.3, p.135-40 (July 1983).
A significant problem with rigid prosthetic stems applied in the finger bones, as well as in other bones of the upper and lower extremity, is resorption of bone at the interface. An investigation was carried out using a plastic plug which would more evenly distribute the stresses to the bone, with fine ridges to produce enhanced fixation by bony ingrowth. A total knee prosthesis in the cat was used as the model, radiographic and histological studies being made at up to one year. A finite element analysis identified areas of high interface and material stresses. With a finely grooved plug, bone ingrowth occurred in all regions except for the region near the bone entry, where the finite element analysis showed the highest interface shear stresses and bone material stresses to occur. (12 refs.)

110243 Pulsatile flow experiments on heart valve prostheses. K.B.Chandran, T.L.Yearwood, C.-J.Chen, H.L.Falsetti (Dept. of Internal Medicine, Univ. of Iowa, Iowa City, IA, USA).
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.529-37 (Sept. 1983).
In vitro fluid dynamic characteristics of aortic valve prostheses were experimentally measured for physiologically relevent pulsatile flows using hot-film velocimetry. The prostheses studied were (i) centrally occluding ball-in cage and (ii) tilting disc valves. The valves sewn to a plexiglass ring were placed in a specially designed valve chamber. The valve chamber was mounted in a mock circulatory system in which glycerol solution was used as the blood analogue fluid. Physiological pulsatile flow experiments were conducted at a time-averaged flow rate of 86.7 $cm^3\ s^{-1}$ (mean Reynolds number of 1320 based on the cross-sectional averaged velocity with a tissue annulus diameter of 27 mm). With the aid of a three-sensor probe, the instantaneous values of the three velocity components (component along the axis, as well as radial and tangential velocity components in a cross-section) were measured and used to compute the mean velocity profiles as well as turbulent normal stresses. The results showed that peak turbulent normal stresses were obtained at 108 ms after the opening of the valves with maximum magnitudes of 110 Pa, 45 mm downstream from the silastic ball valves, compared to about 35 Pa for the stellite ball valve. The largest turbulent normal stresses of about 150 Pa were obtained behind tilting disc valves in the minor flow region parallel to the tilt axis. (17 refs.)

110244 An in vivo method of measurement of the mechanical properties of vascular prostheses: the mechanical properties of saphenous vein bypass grafts. B.L.W.Chapman, D.Charlesworth (Dept. of Surgery, Univ. of Manchester, Manchester, England).
Phys. Med. & Biol. (GB), vol.28, no.9, p.1067-74 (Sept. 1983).
It seems likely that long term patency of small bore vascular prostheses is dependent upon, among other things, the mechanical properties of their walls. Arteries are visco-elastic but there is no accurate method of measuring the visco-elasticity of arterial substitutes in vivo. The most successful vascular substitute is autogenous saphenous vein and it is essential to know its elastic properties if one is to mimic them in prostheses. (Veins rapidly lose their elasticity when excised and measurements made in vitro are unrealistic.) The authors describe an in vivo method which is based on measurements of pressure alone from which they calculate a propagation constant and phase speed, which characterises the visco-elastic behaviour of vein. Sixteen patients who had a femoro-popliteal bypass were studied. Measurements of pressure were used to calculate the phase speed of the pulse and the relationship of phase speed to frequency was calculated. The asymptotic phase speed for human saphenous vein was 13.6 ms^{-1}. (21 refs.)

87.80 BIOPHYSICAL INSTRUMENTATION AND TECHNIQUES

110245 Close-range photogrammetry in predicting animal weight. J.N.Hatzopoulos (Dept. of Civil Engng. & Surveying & Photogrammetry, California State Univ., Fresno, CA, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.41-7 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
The use of photogrammetry to determine dimensional and volume data of animals from a remote distance is investigated. The animal tranquilisation process requires a precise knowledge of the weight of the animal for adjusting the appropriate dosage of medication. Practical experimentation using graphical and analogical processing methods proves that close-range photogrammetry is the best tool for the determination of the correlation between dimensional and volume data and weight of the animal. A practical example of the correlation determination which involved a study of several horses is presented. (8 refs.)

110246 Rotating microscope for Landsat photography of vertebrate embryos. R.Gordon (Pathology Dept., Univ. of Manitoba School of Medicine, Winnipeg, Manitoba, Canada).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.48-52 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A rotating microscope has been developed which can rotate around a single, living embryo. The purpose of this instrument is to allow the investigator to take mosaic images covering the whole surface of the embryo at regular time intervals. Such data is essential to an analysis of the cell motions and interactions involved in the first steps of the morphogenesis of the brain. Because the degrees of freedom and the image processing problems are so similar to photography of the earth from satellites, the author has called this 'Landsat' photography of embryos. (9 refs.)

110247 Biostereometric study of a sample of 50 young adults by photogrammetry. R.Mollard, M.Sauvignon, J.C.Pineau (Lab. d'Anthropologie Appliquee, Univ. Rene Descartes, Paris, France).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.234-40 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A specific photogrammetric device is described. It is composed of one pair of cameras on a vertical base and two vertical mirrors. A sample of 50 young French males was studied by using this method for the purpose of establishing the relationship between overall and segmentary dimensions, surfaces and body volumes and evaluating the variability of these parameters. The conventional anthropometric method and photogrammetry are compared. (19 refs.)

110248 Measurement of reach envelopes with a four-camera selective spot recognition (SELSPOT) system [astronaut application]. J.H.Stramler,Jr. (Northrop Services Inc., Houston, TX, USA), B.J.Woolford.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.241-5 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
A four-camera SELSPOT system received at the Johnson Space Center is thought to be the first such system in the United States. The basic SELSPOT system has been interfaced by the Southwest Research Institute to custom-built hardware to provide a very flexible system. The four cameras provide a 360 degree field of view with a data redundancy which should permit a reduction in the number of missing data point errors. Some test data collected with the system and a brief description of the software used to present it are discussed. (10 refs.)

110249 Cinephotogrammetric evaluation of thoracic deformation due to safety belt action during a crash test. J.P.Verriest (Organisme Nat. de Securite Routiere, Lab. des Chocs et de Biomecanique, Bron, France).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.246-56 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
In order to estimate the thoracic injury tolerance of a belted automobile occupant, and to gain better knowledge about the mechanical behaviour of the belt/torso system, the dynamic deformation of the thorax due to the action of a safety belt load can be measured by cinephotogrammetry. The methodology of data acquisition and processing involved in this technique is described and a few graphical results are given. (7 refs.)

110250 Analysis and display of human wrist motion. S.W.Peterson, A.G.Erdman (Dept. of Mech. Engng., Univ. of Minnesota, Minneapolis, MN, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.257-61 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
The 3D kinematic analysis of the wrist is a complex problem. A method utilizing high speed stereocinematography has been developed to accurately measure the motion of the bones in the wrist. Both relative and absolute motions can be obtained using this system. The system has been shown to accurately locate a point to ±0.003 inch. The 3D motion characteristics of the capitate in radial ulnar deviation were analyzed using this system, and the results are presented. A computer graphics program, developed by the authors, is used to display the motion characteristics of the carpal bones. In this program, the bone surface, defined using a special stereopointer and bicubic surface fitting algorithms, is displayed along with the kinematic data. (8 refs.)

110251 Stereometric analysis of the human body and articular surfaces. Z.Ren-xiang, L.Ming, L.Zu-yun, Z.Hong-zi (Beijing Univ. of Iron & Steel Technol., Beijing, China).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.284-6 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Introduces the method of Moire contourography to measure human body and animal articular surfaces and teeth. Animal articulation surfaces are rather complicated. The authors haven't seen an expression of a complete mathematical formula yet. Hence they adopt Moire contourography to express in three dimensions animal aticular surfaces. The authors also consider the characteristic equation of Moire contourography using an irradiation grating, and the relationship of the contour Moire fringes and influence coefficients. Thus this technique is very useful to measure errors.The authors introduce some of their research on animal articulation surfaces and teeth. (8 refs.)

110252 Stereometric description and analysis of skull growth in P. cynocephalus anubis (Olive Baboon). O.J.Oyen (School of Dentistry, Case Western Reserve Univ., Cleveland, OH, USA), P.E.Lestrel.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.330-7 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
Biostereometric techniques have demonstrated advantages over traditional craniometric methods in describing and analyzing irregular biological forms and form-changes. This paper demonstrates how data obtained with a simple stereoplotting craniostat can be used to precisely describe growth-related changes observed in a cross-sectional collection of olive baboon (Papio cynocephalus anubis) skulls. Data obtained from this extremely prognathic primate species are analyzed using principles of stereographic projections. Demonstrations are made showing how readily understandable representations of other-

wise complex multidimensional shapes and shape changes associated with the skull can be made. (7 refs.)

110253 Three-dimensional perspective display for chicken brain autoradiographs. K.Takaya, S.W.Ellis, J.I.Hasegawa (Dept. of Electrical Engng., Univ. of Saskatchewan, Saskatoon, Canada).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.361, p.338-42 (1983). (Biostereometrics '82, San Diego, CA, USA, 24-27 Aug. 1982).
The glucose metabolism in certain areas of the brain becomes highly active and reflects the degree of the epileptic seizure when evoked. In order to visualize the localization of glucose, C^{14} labeled glucose is used to produce autoradiographs from brain slices in chicken. The areas having a high concentration of C^{14} labeled glucose appear darker in the developed film. This paper describes an image processing computer system which displays 3 dimensional perspective views from the brain slice autoradiographs. The series of autoradiographs were digitized by a video frame grabber. The shape of the brain was displayed 3 dimensionally by means of surface contours and the dark areas representing high glucose concentration was embedded in the outlines. (no refs.)

110254 Accurate measurement of flash-evoked alpha attenuation. B.Kemp (Dept. of Clinical Neurophysiology, Univ. Hospital, Leiden, Netherlands).
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.248-53 (Aug. 1983).
An accurate method for measuring flash evoked alpha attenuation has been derived, based on a model of the alpha generator. The method has been applied to 10 healthy volunteers in order to determine their alpha attenuation latencies (AALs). For the 9 subjects which showed at least some alpha rhythm, the AAL group mean is 95 msec. The AAL inaccuracy (SD 5 msec) is smaller than interindividual differences (SD 13 msec). There exists no relationship between the AAL and the frequency of the alpha rhythm. (16 refs.)

110255 Detection of reaction time by an adaptive filter based on the least squares fit. D.G.Ruegg, A.Eichenberger (Inst. of Physiology, Univ. of Fribourg, Fribourg, Switzerland).
Electroencephalogr. & Clin. Neurophysiol. (Netherlands), vol.56, no.2, p.256-8 (Aug. 1983).
An adaptive filter based on the least squares fit between a template and individual records was developed. It has been applied to compute reaction times of a voluntary movement. Its performance was tested by comparing these reaction times with the latency of the EMG responses. Different properties of the least squares fit technique and Woody's filter technique (Woody 1967) are discussed. (6 refs.)

110256 512-channel X-ray DARK-2.0 diffractometer with a mosaic detector for investigating protein single crystals. B.K.Vainshtein, N.I.Komyak, F.P.Reznikov, D.A.Goganov, D.M.Kheiker, A.V.Mirenskii, A.Z.Pliss, O.I.Ageev, V.M.Shul'meister.
Instrum. & Exp. Tech. (USA), vol.25, no.6, pt.2, p.1492-8 (Nov.-Dec. 1982). Translation of: *Prib. & Tekh. Eksp. (USSR)*, vol.25, no.6, p.160-5 (Nov.-Dec. 1982).
Describes the design and the characteristics of the 512-channel X-ray DARK-2.0 diffractometer with a mosaic detector for research on protein single crystals. The research technique and the results of an experimental evaluation of the instrument are described. Since all diffractive reflections in 4-layer planes can be simultaneously recorded with a resolution of 2 Å, the recording speed on the DARK-2.0 was increased 30 times over that of the single-channel DAR-UMB diffractometer. Recordings of single crystals of lung hemoglobin protein (α=92.95 Å; b=38.31 Å, c=52.15 Å; and γ=99°) and its five derivatives were made with a resolution of 2 Å (150000 reflections) and confirmed the high accuracy and speed of operation of the instrument. (19 refs.)

110257 Nuclear instrument maintenance—problems, solutions, and obstacles. P.H.Vuister.
Int. At. Energy Agency Bull. (Austria), vol.25, no.2, p.24-9 (June 1983).
To guarantee reliable results and effective use of invested capital, maintenance and quality control of instruments are essential for laboratories involved in research, analysis of samples, and medical diagnostics. Badly maintained or inoperable instruments entail important economic losses and social hardship. Nevertheless, expert reports, technical co-operation requests, recent surveys on use and maintenance of nuclear medicine instruments, and many other sources, reveal frequent breakdowns and insufficient maintenance and quality control of nuclear equipment. Nuclear medicine instruments in particular, which are expensive and relatively sophisticated, need regular checks and are difficult to maintain in good working order, especially in developing countries. (4 refs.)

110258 A new conductive substrate for preparing cells in suspension for scanning electron microscopy. H.Kumon, K.Ohno, Y.Matsumura, H.Ohmori (Dept. of Urology, Okayama Univ. Medical School, Okayama, Japan), T.Tanaka.
J. Electron Microsc. (Japan), vol.32, no.1, p.20-6 (1983).
Improvement in conductibility of substrates was attempted to overcome a technical problem of charging artifacts caused by limited cell surface attachment to the substrates, when cells prefixed in suspension are observed under SEM. Gelatin-covered slips were impregnated with osmium vapor and coated with polylysine. Using the newly-designed slips, the authors have succeeded in the elimination of the charging artifacts, such as irregular bright and dark lines parallel to the scan direction or abnormal contrast by a higher magnification. Subsequently, a mesh containing 42 compartments in 25 mm^2 was prepared by drawing sharp lines on the above conductive substrates. With a combined use of SEM with light microscopy, this particular mesh has solved another problem of differentiating individual cells in mixed cell populations. (11 refs.)

110259 Estimation of the mean size of spheres from the profiles in ulthrathin sections: a stereological method. K.Abe (Dept. of Anatomy, Hokkaido Univ., School of Medicine, Sapporo, Japan), S.Matsushima, M.Mita.
J. Electron Microsc. (Japan), vol.32, no.1, p.57-60 (1983).
The authors have found that a mean area, a, of the sectional profiles of spheres of varying size cut into infinitely thin sections gives the size of the largest sectional profile, A, which representatively indicates the three dimensional size of the spheres by a formula, $A \approx (3/2)\bar{a}$. From this stereological principle, one can easily and quickly estimate the approximate size of spherical objects from a relatively small number of profiles. This is especially convenient and useful in finding the size of larger objects, such as nuclei and cells, where it is difficult to get a large number of profiles for measurements in one population, and may also be useful in obtaining the mean size of any spherical object by electron microscopy. (12 refs.)

110260 A new embedding medium available for stereoscopic observation of semi-thin sections under 200 kV transmission electron microscope. H.Kushida (Electron Microscope Labs., Keio Univ., Tokyo, Japan), T.Kushida, K.Yonehara, E.Nakazawa.
J. Electron Microsc. (Japan), vol.32, no.1, p.61-5 (1983).
A new embedding medium, 'Quetol 812' is found to be satisfactory for the observation of semi-thin sections of biological specimens at an accelerating potential of 200 kV with a conventional TEM, because of its low electron scattering property. 200 kV TEM images of 0.5 and 1.0 μm Quetol 812-embedded sections of mouse seminiferous tubule. (3 refs.)

110261 The use of fluorescent tracers in the peripheral sensory nervous system. D.C.M.Taylor, Fr.-K.Pierau, H.Schmid (Max-Planck-Inst. fur Physiologische und Klinische Forschung, Bad Nauheim, Germany).
J. Neurosci. Methods (Netherlands), vol.8, no.3, p.211-24 (July 1983).
Describes an injection technique which simplifies the use of fluorescent tracers in investigating the projections of peripheral nerves both in rats and pigeons, and avoids the difficulties experienced with the cut nerve technique. The tracers are injected into the peripheral nerve and transported to cell bodies in the dorsal root ganglia (DRG). By a careful choice of tracer it is possible to investigate the projections of two or more nerves in the same preparation. The authors have used two combinations of tracer which can be viewed simultaneously in the cell at the same excitation wavelength (405 nm): (1) propidium iodide and bisbenzimide which produce an orange cytoplasmic fluorescence and blue nuclear fluorescence respectively; and (2) fast blue and nuclear yellow which label the cytoplasm blue and the nucleus yellow. This distribution of tracers is similar to that reported in central neurones but differs from that reported in the efferent peripheral nervous system. Using these tracers the authors have observed double-labelled neurones in the DRG of both rats and pigeons, which is an indication for the dichotomizing of peripheral fibres. The existence of two tracers in double-labelled cells has been confirmed microspectrophotometrically. (22 refs.)

110262 A new photographic method for mapping spatio-temporal receptive field using television snow stimulation. E.Hida, K.Naka, K.Yokoyama (Nat. Inst. for Basic Biology, Okazaki, Japan).
J. Neurosci. Methods (Netherlands), vol.8, no.3, p.225-30 (July 1983).
A means was devised to measure simultaneously spatial as well as temporal characteristics of visual receptive fields by stimulating the retina with the noise obtained on an unused television channel. The input, television snow, and the output, neural response, were recorded on a video tape. The tape was played back to obtain the (linear) spatio-temporal Wiener kernel by cross-correlating the input with the output. This method can be applied to extract the linear part of the visual responses in time and space. (12 refs.)

110263 Fiber microelectrodes for electrophysiological recordings. H.J.Reitboeck (Dept. of Appl. Phys. & Biophys., Philipps-Univ., Marburg, Germany).
J. Neurosci. Methods (Netherlands), vol.8, no.3, p.249-62 (July 1983).
Methods for the fabrication of tungsten-glass and platinum-rhodium-quartz fiber microelectrodes and of fiber pipettes are described and the electrical and mechanical properties of fiber electrodes are discussed. These properties (minimal tissue damage, good single unit isolation and temporal stability) make them particularly suited for multielectrode recordings from the central nervous system. (36 refs.)

110264 The development of linear sweep voltammetry with carbon paste electrodes in vivo. R.D.O'Neill, M.Fillenz, W.J.Albery (Lab. of Physiology, Univ. of Oxford, Oxford, England).
J. Neurosci. Methods (Netherlands), vol.8, no.3, p.263-73 (July 1983).
A number of advances have been made in the application of linear sweep voltammetry with carbon paste electrodes to the monitoring of ascorbate and monoamine neuroregulator metabolities in the brain of the freely-moving rat. These new measures are: the reduction of the sweep rate of 5 mV/s; the elimination of semidifferentiation in chronic recordings; the measurement in situ and subtraction of the background current for each electrode; the reduction, to practically zero levels, of the ascorbate signal in alternate scans; and corrections for circadian changes. These innovations enable one to monitor changes in the monoamine metabolities, even when there are simultaneous, large changes in ascorbate. (12 refs.)

110265 Multioscillator simulator for gastrointestinal electrical activity modelling. D.A.Linkens, M.Khelfa, G.Nicklin (Dept. of Control Engng., Univ. of Sheffield, Sheffield, England).
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.591-8 (Sept. 1983).
Describes a coupled 64-oscillator electronic simulator for modelling electrical slow-wave activity in the mammalian gastrointestinal digestive tract. The individual oscillator dynamics are based on an electronic implementation of the Hodgkin-Huxley membrane equations. The simulator is constructed to allow for versatility in terms of setting oscillator waveshapes and frequencies and intercoupling parameters. It also allows for automatic readout of the model frequency profile, which is one of the main features studied in gastrointestinal electrical activity. Results are shown illustrating frequency plateaus in a coupled chain of oscillators which have a frequency gradient when uncoupled. Frequency entrainment is also shown for the simulator connected as a tubular structure. (15 refs.)

110266 An eye movement recording method operating with a closed eye. B.Comet (Lab. de Physiologie, Faculte de Medecine, Toulouse, France).
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.628-31 (Sept. 1983).
An eye movement recorder, based on an optoelectronic method, can be used in closed or open eye situations. Three photodiodes are used as proximity sensors. This eye tracker is well adapted for the studies of eye movement in after-image phenomena. (14 refs.)

110267 Identification of r.e.m. sleep in the mouse by measuring the body movements. A.Higashi (Nat. Inst. for Physiological Sci., Okazaki, Japan).
Med. & Biol. Eng. & Comput. (GB), vol.21, no.5, p.644-6 (Sept. 1983).
Recently Higashi et al. (ibid., vol.17, p.131-2, 416-8, 1979) have developed a compact accelerator, the so-called 'BM transducer', for detecting minute body movements of a mouse (size: 5 mm × 5 mm; weight: 0.92 g). This report indicates that the body movements thus recorded could serve as a definitive index for identifying the r.e.m. sleep of mice. (3 refs.)

110268 Determination of twist and handedness of a 39-base pair segment of DNA in solution. S.Iwamoto, Ming-Ta Hsu (Rockefeller Univ., New York, NY, USA).
Nature (GB), vol.305, no.5929, p.70-2 (1 Sept. 1983).
A new method is presented for determining the helical parameters of a segment of DNA in solution. It is the first non-crysallographic method that can directly determine both the helical periodicity and the absolute handedness of DNA. The results obtained using this method are consistent with the classical Watson-Crick right-handed double helical model. (11 refs.)

110269 Computed tomography for measuring annual rings of a live tree. M.Onoe, Jing Wen Tsao, H.Yamada (Inst. of Industrial Sci., Univ. of Tokyo, Tokyo, Japan), H.Nakumura, J.Kogure, H.Kawamura, M.Yoshimatsu.
Proc. IEEE (USA), vol.71, no.7, p.907-8 (July 1983).
A portable X-ray computed-tomography (CT) scanner has been developed for the nondestructive measurement of cross sections of live trees, wooden utility poles, wooden building columns, wooden statues, etc. in the field environment. Temporal resolution of CT reconstruction is good enough for observing details of annual rings of trees. The scanner will be useful in plant physiology, environment assessment, safety assurance of poles, archaeology, and dendrochronology. (2 refs.)

110270 Quality improvement of white blood cell images by using a 2-D digital filter. K.Taniguchi, H.Ito, S.Susanto (Faculty of Engng., Fukui Univ., Fukui, Japan).
Trans. Inst. Electron. & Commun. Eng. Jpn. Part D (Japan), vol.J66D, no.6, p.753-4 (June 1983). In Japanese.
Deals with the enhancement of granules in white blood cells images. Taking the distribution of power spectrum of white blood cell images into account, the enhancement of granules was accomplished by using a 2-D high emphasis digital filter. By this processing, extraction of granules becomes easy. (4 refs.)

110271 A microprocessor based system for real time volume measurement of the instrumented, beating canine left ventricle [using ultrasound]. D.K.Medema, W.E.Moritz, A.S.Pearlman, K.Haneda, R.Thomas, D.G.Brazeale, D.H.Dillard (Univ. of Washington, Seattle, WA, USA).
Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.473-6
A system has been developed which can accurately and repeatably measure the volume of the beating canine left ventricle (LV) in real time. The system consists of a plastic cylindrical volume chamber (VC) which is connected by rigid tubing to a nylon mounting fixture inserted into the mitral orifice. A balloon is attached to the nylon fixture and the VC, and balloon filled with water. The instantaneous water level in the VC is determined using a sonar transducer. The water level is converted to a volume measurement by a microprocessor and displayed on a video display. Static accuracy is better than 0.5 cc over a 0-10 cc range. No perceptible tracking errors are evident when the VC system is driven by a pulsatile pump. The system appears appropriate for use as a reference standard during in vivo echocardiographic studies of LV volume. The authors are now using the system for LV volume studies in an open-chest dog model. (9 refs.)

110272 A context-sensitive approach to long-term ECG arrhythmia analysis. M.Ebele (LERS, Bagneux, France).
Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.505-8
A context-sensitive approach to long-term ECG syntactic analysis is presented. The basic idea consists of coupling a finite-state automaton for pattern-primitives string generation to a linearly bounded memory automaton for paradigmatic error analysis of characters in the string. The context sensitive grammar is used as a semantic smoother or as a fuzzy analyser. Signal preprocessing is achieved by a 2nd order polynomial digital filter and the first derivative is selected. This method has been implemented on a DEC LSI11/03 microprocessor running under a very stripped down version on the UNIX operating system. After a six month off-line evaluation period, it is now in everyday use for the screening of long-term and often noisy ECGs in conscious dogs during drug evaluation in the LERS Cardiovascular Department. The system is now used to control the deviation from some specific standard cardiac state in order to measure the drug's actual effect. (10 refs.)

110273 Quantitative phono study of intracardiac and external heart sounds. A.E.Aubert, B.G.Denys, H.De Geest, F.Meno, P.S.Reddy.
Computers in Cardiology. Ninth Meeting of Computers in Cardiology, Seattle, WA, USA, 12-15 Oct. 1982 (Silver Spring, MD, USA: IEEE Computer Society Press 1983), p.501-4
In 11 closed chest dog experiments left ventricular pressure, left apexcardiogram and quantified intracardiac and external heart sounds were recorded simultaneously using infinite time constant piezo-resistive pressure transducers with equal sensitivity and frequency response. Various hemodynamic interventions were made in order to induce changes in heart sounds, especially to generate diastolic sounds (S_3 and S_4). All signals were recorded on multichannel FM tape with identical settings. Spectral analysis of isolated sounds was performed using fast Fourier transform to determine the frequency content. The intensity of the sounds was uniformly greater over the chest wall than inside the left ventricle. Diastolic sounds were visible on the external recordings and could not be discerned on the internal recording. This new method of analyzing quantified internal and external heart sounds gives valuable information on the mode of generation and transmission of these sounds. (15 refs.)

110274 An updated Bouguer anomaly map of south-central West Africa. D.A.Hastings (Technicolor Government Services Inc., Sioux Falls, SD, USA).
Geophysics (USA), vol.48, no.8, p.1120-8 (Aug. 1983).
A new Bouguer gravity anomaly map compiled for western Africa adds data for Ghana, Guinea, and Liberia. The new data add detail to a key part of the Eburnean shield and assist in the development of a model of rifting at the time of the Eburnean orogeny, 2000 million years ago. This model includes a framework for the deposition of the region's mineral deposits. The model and existing field data can be used to guide future minerals exploration in the region. (56 refs.)

110275 Gravity interpretation of two dimensional fault structures using Hilbert transforms. N.Sundararajan, N.L.Mohan, S.V.Seshagiri Rao (Centre of Exploration Geophys., Osmania Univ., Hyderabad, India).
J. Geophys. (Germany), vol.53, no.1, p.34-41 (1983).
The Hilbert transform of the second order horizontal gradient of the gravity effect of a two dimensional dipping fault is derived. Using the derivatives of the horizontal gradient of the gravity effect and the Hilbert transform, the parameters of the dipping fault, namely the dip, the depths to the top and bottom and the density contrast, are obtained. The gravity effect of the vertical fault has also been analysed treating it as a particular case of the dipping fault. (9 refs.)

110276 Inertial surveying and geodesy. K.P.Schwarz (Div. of Surveying Engng., Univ. of Calgary, Calgary, Alberta, Canada).
Rev. Geophys. & Space Phys. (USA), vol.21, no.4, p.878-90 (May 1983).
Outlines the basic theory of using the output of an inertial measuring unit to obtain geodetically meaningful results. Emphasis is on the development of appropriate mathematical models and estimation procedures rather than on hardware aspects. A discussion of results to date and an outlook on future applications concludes the presentation. (42 refs.)

110277 Nonuniformity of the Earth's rotation within a day. G.P.Pil'nik (P.K. Shternberg State Astron. Inst., Moscow, USSR).
Sov. Astron. (USA), vol.26, no.6, p.712-15 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1184-9 (Nov.-Dec. 1982).
The possibility of using astronomical observations of the International Time Service to study the intradiurnal nonuniformity of the Earth's rotation is discussed. A spectral analysis of data for 1968-1978 shows that waves with diurnal and semidiurnal periods are contained in these observations. Attention is drawn to the necessity of improving the organization of Time Service observations in connection with the formulation of the new scientific problem. (7 refs.)

91.25 GEOMAGNETISM AND PALAEOMAGNETISM; GEOELECTRICITY

110278 Interpretation of aeromagnetic data of Damanhour area west of the Nile Valley, Egypt. R.I.Rizkalla (Dept. of Geology, Univ. of Baghdad, Baghdad, Iraq).
Iraqi J. Sci., vol.23, no.1, p.107-26 (1982). [received: Aug. 1983]
Both qualitative and quantitative interpretation of magnetic data in the area under investigation is tried. The quantitative analysis of the magnetic data results in the construction of a tentative basement relief map which illustrates the general geological setup of the basement rocks in the area. This mainly shows the presence of two sets of faults affecting the area. The depth to the basement surface is found to range between 2 to 5 km. (7 refs.)

110279 Changes in the geomagnetic total force intensity associated with the anomalous crustal activity in the eastern part of the Izu Peninsula. IV. Anomalous change observed in the north-eastern area in 1981. Y.Sasai, Y.Ishikawa (Earthquake Res. Inst., Univ. of Tokyo, Tokyo, Japan).
Bull. Earthquake Res. Inst. Univ. Tokyo (Japan), vol.57, pt.4, p.739-57 (1982). In Japanese.
For pt.III see ibid., vol.55, no.4, p.1101-13 (1980). The eastern-Izu magnetometer array detected a transient decrease in the total intensity in the north-eastern area of the Izu Peninsula during the period from July to October, 1981. The anomaly was found within an area with a 10 km radius, centered on Ito city, where the crustal uplift is still continuing. The total field differences showed spurious bay-like variations from Dec., 1980, to Feb.,

1981, and from Dec., 1981, to Jan., 1982, owing to transient increase of the F component at reference station KNZ. The total field variations at 11 standard observatories in the Kanto and Tokai districts are plotted. In order to interpret the transient anomaly on Izu, the piezomagnetic field associated with a macroscopic model by crustal dilatancy is investigated. (27 refs.)

110280 Palaeomagnetism of Carboniferous rocks of the central Sahara; analysis of juxtaposed magnetisations; configuration of Pangea. L.Daly (Lab. de Geomagnetisme, Univ. de Paris 6, Saint-Maur-des-Fosses, France), E.Irving.
Ann. Geophys. (France), vol.1, no.3, p.207-15 (May-June 1983). In French.
Two rock-units of red-beds (Ain Ech Chebbi and Hassi Bachir Formations) of middle Carboniferous age from the central Sahara have been studied. Three components have been identified. The first has been acquired in the recent geomagnetic field. The second is a strong and pervasive magnetization in the Hassi Bachir Formation that seems to have been acquired during a period of weak folding in the early Permian; it gave a paleopole before correction for tilting of beds at 35.5°S, 60.0°E, $A_{95}=4.6°$. The third is thought to date from the time of the diagenesis; the Ain Ech Chebbi Formation (lower Moscovian) yielded a paleopole (after correction for tilting of beds) at 22.9°S, 51.8°E $A_{95}=6.3°$; the Hassi Bachir Formation (lower Moscovian to upper Namurian) yielded a paleopole after correction for tilting of beds at 26.8°S, 56.6°E, $A_{95}=3.7°$. The overall mean paleopole for the two units based on 11 sites is 25.4°S, 54.8°E, $A_{95}=3.5°$, $K=149$. The paleopoles when compared with results from North America and Europe are inconsistent with Wegener-type reconstructions but are consistent with the reconstructions of Van der Voo and French (1974) and Irving (1977) in which Gondwana is rotated by different amounts relative to the northern continents. (28 refs.)

110281 Analytic comparison of apparent polar wander paths. B.J.J.Embleton (CSIRO Div. of Mineral Phys., North Ryde, Australia), N.I.Fisher, P.W.Schmidt.
Earth & Planet. Sci. Lett. (Netherlands), vol.64, no.2, p.276-82 (Aug. 1983).
Develops an iterative technique which can be used to match paths on the surface of a sphere on an objective basis. The notion of a minimum combined path length from a comparison of two data sets is used to determine the optimal match-up. The technique is appropriate to cases where the only dating available for the points on each path is their relative chronology. (27 refs.)

110282 The harmonic and transient electromagnetic response of a thin dipping dike. P.Weidelt (Bundesanstalt fur Geowissenschaften & Rohstoffe, Hannover, Germany).
Geophysics (USA), vol.48, no.7, p.934-52 (July 1983).
An exact solution is given for the electromagnetic induction in a dipping dike of finite conductivity, represented as a thin half-sheet in a nonconducting surrounding. The problem is formulated for arbitrary dipole or circular loop T_x-R_x configurations. The formal solution obtained by the Wiener-Hopf technique is cast into a rapidly convergent triple integral suitable for an effective numerical treatment. A good agreement is found between numerical results and analog measurements available for harmonic excitation. The transient response is obtained as a superposition of the half-sheet free-decay modes and is illustrated by some numerical examples for coincident loops, including a diagram for the approximate determination of conductance and depth of a vertical dike. (31 refs.)

110283 Finite-difference calculations of the transient field of an axially symmetric Earth for vertical magnetic dipole excitation. M.M.Goldman (Inst. for Petroleum Res. & Geophys., Holon, Israel), C.H.Stoyer.
Geophysics (USA), vol.48, no.7, p.953-63 (July 1983).
A finite-difference formulation of the coaxial-loop or wire-loop transient electromagnetic prospecting systems is used to model the fields from a buried cylindrical conductor whose axis is coincident with that of the field system. Solutions are obtained directly in the time domain. The variable-directions method reduces each advance of one step in time from one 2-D problem to a large number of one-dimensional (1-D) problems. In order to avoid including the air in the finite-difference grid, an integral equation approach is used to formulate the surface boundary condition. All computations are carried out for a perfectly conducting basement. (19 refs.)

110284 Airborne resistivity mapping using a multifrequency electromagnetic system. A.K.Sinha (Geological Survey of Canada, Ottawa, Ontario, Canada).
Geophys. Prospect. (Netherlands), vol.31, no.4, p.627-48 (Aug. 1983).
A three-frequency airborne EM survey carried out over an area northwest of Timmins, Ontario, was interpreted in terms of thickness and resistivity of the layers of a two-layer Earth section. Based on prior geological information and a preliminary interpretation of the field records, two two-layer models of the subsurface seemed to be appropriate for most of the survey area. An automatic computerized interpretation procedure was devised to interpret the field data at each point in terms of thickness and resistivity parameters of those two models. (28 refs.)

110285 The integral-finite-difference method for calculating transient electromagnetic fields in a horizontally stratified medium. M.M.Goldman (Inst. for Petroleum Res. & Geophys., Holon, Israel).
Geophys. Prospect. (Netherlands), vol.31, no.4, p.664-86 (Aug. 1983).
A finite-difference solution and an integral algorithm are developed for computing time-domain electromagnetic fields generated by an arbitrary source located in a horizontally stratified earth. The finite-difference problem is first solved for the kernel of an integral Bessel transform of the desired field and then an inverse transformation is performed either by numerical integration or by linear filtering. A description of the appropriate algorithm as well as numerical results are presented for two cases: an axially symmetric source placed on the surface of a horizontally layered section overlying either an insulating or an ideally conducting basement. (25 refs.)

110286 Application of mantle filter theory to the magnetic jerk of 1969. G.E.Backus (Inst. of Geophys. & Planetary Phys., Scripps Inst. of Oceanography, Univ. of California, San Diego, La Jolla, CA, USA).
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.713-46 (Sept. 1983).
Data relevant to the electrical conductivity κ in the lower mantle are rare, hard to interpret, and often not very precise. Current estimates of that conductivity disagree by two orders of magnitude. The data are certainly too sparse to support any particular conductivity profile in the lower half of the mantle. The present paper is an attempt to obtain certain averages or other coarse properties of that profile by refining Runcorn's (1955) theory of geomagnetic impulses and applying the results to the 1969 impulse. (31 refs.)

110287 On multifrequency magnetotelluric sounding over the Himalayan type colliding plate boundaries. P.D.Saraf, J.G.Negi (Theoretical Geophys. Group, Nat. Geophys. Res. Inst., Hyderabad, India).
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.809-17 (Sept. 1983).
Deep linear structures and deep parallel fractures often signify the tectonic zones of colliding plate boundaries of the Himalayan type. Knowledge of the electrical properties of the upper mantle in such areas can provide a good understanding of tectonic processes in these zones. However, the electrical anisotropy in these crustal formation introduces uncertainties in the interpretation of the magnetotelluric data. Hence, an attempt is made to estimate the effects of dipping anisotropy in probing such tectonically active areas. Numerical results in comparison with isotropic and non-dipping conditions display the extent of change in the surface impedance parameter, at different frequencies, for several dipping anisotropic conditions usually occurring at the plate boundaries. It is also shown that the multifrequency measurements provide fairly good estimates of resolving such complex crustal formations. (6 refs.)

110288 Boundary conditions for a rapidly rotating hydromagnetic system in a cylindrical container. D.R.Fearn (Dept. of Appl. Math. & Theoretical Phys., Univ. of Cambridge, Cambridge, England).
Geophys. & Astrophys. Fluid Dyn. (GB), vol.25, no.1-2, p.65-75 (1983).
A conducting fluid is contained in a cylindrical annulus with rigid, perfectly conducting boundaries and is permeated by a magnetic field $\mathbf{B}_0=B_0(s)\phi$ (where (s,ϕ,z) are cylindrical polar coordinates). The equations governing the linear stability of this system are separable in ϕ,z, and time t, and form a tenth-order boundary-value problem in s. The five conditions which must be satisfied at each boundary are $\mathbf{u}.\hat{\mathbf{s}}=0$, $\mathbf{u}\times\hat{\mathbf{s}}=0$ and $\mathbf{e}\times\hat{\mathbf{s}}=0$ where $\mathbf{u}$ is the fluid velocity and $\mathbf{e}$ the electric field. The system of equations reduces to sixth order and the noslip conditions can no longer be applied. A complication arises when waves on a timescale long compared with the rotation period are of interest, because then the equations reduce to fourth order and it is unclear what are the correct boundary conditions to be applied. A boundary-layer analysis shows that the normal magnetic field and a linear combination of the normal velocity and tangential current must vanish at the edge of the mainstream. (6 refs.)

110289 The Rikitake two-disc dynamo system and the Painleve property [Earth MHD dynamo]. W.-H.Steeb (Theoretische Phys., Univ. Paderborn, Paderborn, Germany), A.Kunick, W.Strampp.
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2649-53 (Aug. 1983).
To find integrable and nonintegrable regions of the Rikitake two-disc dynamo system the authors investigate its Painleve property. This means they perform a singular point analysis. This analysis gives one a hint where global constants of motion exist. Related systems are also investigated. (15 refs.)

110290 Palaeomagnetism of alkali basalts occurring in Takakusayama and Ryuso districts, south-central Honshu, Japan. S.Tonouchi, K.Kobayashi (Ocean Res. Inst., Univ. of Tokyo, Tokyo, Japan).
J. Geomagn. & Geoelectr. (Japan), vol.34, no.11-12, p.587-600 (1982).
Directions of stable natural remanent magnetisation as well as thermomagnetic and opaque-mineralogical characteristics of alkali basalts occurring in Takakusayama and Ryuso districts immediately east (in the oceanside) of the Setogawa ophiolite belt indicate that the alkali basalts were formed as seamounts for post-spreading volcanics, partly emerged at one time, at a site not far from the present location. The masses of alkali rocks were dissected by the normal faults with a strike of N40°E and then accreted along the outer margin of the Setogawa ophiolite belt. (9 refs.)

110291 Geomagnetic paleointensities for the period 6000 to 3000 years BP determined from lavas and pyroclastic flows in Japan. H.Tanaka (Dept. of Appl. Phys., Tokyo Inst. of Technol., Tokyo, Japan).
J. Geomagn. & Geoelectr. (Japan), vol.34, no.11-12, p.601-17 (1982).
Paleointensity of the geomagnetic field was studied with precisely dated lava flows and pyroclastic flows in Japan older than 3000 years BP by the Thellier's (1959) stepwise heating method. The errors inherent in the ages of the rocks are fully evaluated. Samples collected from five lava flows and three pyroclastic flows provide successful results. Two examples are found indicating that the apparent linear NRM-TRM relation in the Arai (1963) diagram is probably due to the effect of TCRM produced during heat treatment. This phenomenon is detected by comparing the result with with those from other specimens taken from the same flow and treated with the same procedure in the Thellier's experiment simultaneously with two samples mentioned above. This result strongly suggests that the Thellier's experiment should be done by using multiple at least three specimens. (36 refs.)

110292 Peninsula effects in central Japan and their relation to the electrical conductivity structure. Y.Honkura (Dept. of Appl. Phys., Tokyo Inst. of Technol., Tokyo, Japan).
J. Geomagn. & Geoelectr. (Japan), vol.35, no.2, p.39-56 (1983).
Unusually large amplitudes of the Z-component of short-period geomagnetic variation have often been observed at coastal areas. In most cases, this type of anomaly is associated with an irregular shape of coastline particularly like a peninsula-like jut. In this sense the anomaly may be called the peninsula effect. The difference between the coast and peninsula effects arises from local perturbation of induced electric currents flowing in a conducting sea due to the presence of a less conducting peninsula. A method is put forward to estimate numerically such perturbation. Basically it is a combination of numerical methods used for the coast and island effects. This method is then applied to the peninsula effects observed in the Izu and Kii Peninsulas, central Japan. (26 refs.)

110293 Electrical conductivity beneath Iceland—constraints imposed by magnetotelluric results on temperature, partial melt, crust-and mantle structure. M.Beblo (Inst. fur Allgemeine und Angewandte Geophys., Univ. Munchen, Munchen, Germany), A.Bjornsson, K.Arnason, B.Stein, P.Wolfgram.
J. Geophys. (Germany), vol.53, no.1, p.16-23 (1983).
Magnetotelluric results from 38 sites in North Iceland yield a detailed spatial distribution of conductivity versus depth. A high-conductivity layer, about 10 Ωm, marking the transition between crust and upper mantle is detected throughout the surveyed area. The high conductivity layer indicates some basaltic melt fraction at temperatures around 1000°C. Below this anomalous zone down to 150 km depth, the conductivity increases to 100 Ωm. However, a highly conducting asthenosphere exists below 150 km depth. A petrological model for Iceland is suggested. (29 refs.)

110294 Computer synthesis of geomagnetic palaeosecular variations. K.M.Creer (Dept. of Geophys., Univ. of Edinburgh, Edinburgh, Scotland).
Nature (GB), vol.304, no.5928, p.695-9 (25 Aug. 1983).
Computer models, designed to synthesize palaeosecular variations of the geomagnetic field, cast doubt on some widely accepted palaeomagnetic dogmas. Westward (or eastward) drift cannot be uniquely deduced from the sense of rotation of the geomagnetic vector: the use of unit vectors in statistical analyses leads to systematic errors which render investigation of the global symmetry of the palaeofield more difficult than previously supposed. At least some geomagnetic 'excursions' may be regarded as large-amplitude secular variations. (30 refs.)

110295 Tectonomagnetism. P.M.Davis (Dept. of Earth & Space Sci., Univ. of California, Los Angeles, CA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.685-93 (April 1983).
The magnetization of crustal rock is influenced by stress by virtue of piezomagnetic effects in crystals of magnetic minerals. Crustal stress changes in

tectonic zones are therefore expected to generate changes in the crustal component of the geomagnetic field and so provide a mechanism for monitoring stresses. Observations of several tectonomagnetic effects were reported and the method of observation improved using predictive filtering techniques to remove the disturbing influence of ionospheric and magnetospheric activity. The possibility that fluid flow in the crust might generate magnetic fields comparable to those due to stress changes was evaluated. (43 refs.)

110296 Induction of currents in long submarine cables by natural phenomena. S.Meloni (Istituto Nazionale di Geofisica, Osservatorio Geofisico Monte Porzio, Rome, Italy), L.J.Lanzerotti, G.P.Gregori.
Rev. Geophys. & Space Phys. (USA), vol.21, no.4, p.795-803 (May 1983).
The influence of induced currents on long submarine cables has been observed for nearly a century. The currents originate from time variations in the magnetic field of external origin (magnetospheric, atmospheric tides) and Earth and ocean tides. Steady Earth currents of internal origin have also been proposed as a possible source. The induced currents will depend upon the length, depth, and geomagnetic location of the cables. Present understanding of the phenomena is reviewed. Potential scientific problems which might be addressed with data from such long cables are also discussed. (92 refs.)

110297 Interpretation methods for magnetometer arrays. D.I.Gough, M.R.Ingham (Inst. of Earth & Planetary Phys., Univ. of Alberta, Edmonton, Alberta, Canada).
Rev. Geophys. & Space Phys. (USA), vol.21, no.4, p.805-27 (May 1983).
The authors review interpretation methods for magnetometer array studies. Such studies investigate structure in the Earth to depths of about 600 km using induction by various external current systems. The use of magnetograms and Fourier transform anomaly maps for identification and location of induced currents is discussed. Characteristics of various types of anomalies are considered. This is followed by a discussion of the separation of time-varying fields into external and internal parts by the use of surface integration. Transfer function analysis is discussed in detail. Methods of one-dimensional modeling and inversion are followed by a discussion of four methods of numerical modeling of two-dimensional structures. (115 refs.)

110298 On a basic model in magnetotelluric field theory and some applications. J.Pecaric (Gradevinski Fakultet, Beograd, Yugoslavia).
Tehnika (Yugoslavia), vol.38, no.6-7, p.E1-5 (1983). In Croatian.
Evaluates formulae for the magnetotelluric field of an n-layer media having some high resistance layers. The results have application to an Earth model with periodical two-layer repetition. Magnetotelluric sounding in the Alibunar region of Yugoslavia is also presented. (4 refs.)

91.30 SEISMOLOGY

110299 Microseismic recording at Hemren Dam area—east central Iraq. S.A.Alsinawi, T.K.Al-Nasiri (Dept. of Geology, Univ. of Baghdad, Baghdad, Iraq).
Iraqi J. Sci., vol.23, no.2, p.238-50 (1982). [received: Aug. 1983]
A local triangular seismograph network consisting of three single (Z) component short period seismic systems (Kinemetrics PS 1A) was used to investigate the microseismicity of Hemren Dam area during the period from April 4th to May 16th, 1979. Statistical analysis is used to determine parameters such as the average rate of microearthquake occurrence (2.74 event/day), the change of seismicity with time and amplitude-duration relation. (12 refs.)

110300 Spectra of the first higher mode of simulated oceanic Rayleigh waves generated by deep earthquakes of the dip-slip type. M.Yoshida (Earthquake Res. Inst., Univ. of Tokyo, Tokyo, Japan).
Bull. Earthquake Res. Inst. Univ. Tokyo (Japan), vol.57, pt.4, p.609-24 (1982).
For the purpose of understanding the excitation of the first higher mode of oceanic Rayleigh waves, the waves are simulated for seismic sources with a pure dip-slip motion along a vertical fault plane, for various focal depths from 10 to 500 km. It is suggested that the first higher mode of oceanic Rayleigh waves generated by deep earthquakes with focal depth of about 200 or 300 km can be observed in the period range from 20 to 50 seconds, with amplitude exceeding that of the fundamental mode. The optimum filtering parameters for the analysis of dispersed oceanic Rayleigh waves are determined. (36 refs.)

110301 Accuracy of the initial phase and the phase velocity of surface waves with special reference to the single-station method. M.Yoshida (Earthquake Res. Inst., Univ. of Tokyo, Tokyo, Japan).
Bull. Earthquake Res. Inst. Univ. Tokyo (Japan), vol.57, pt.4, p.627-52 (1982).
The initial phase of surface waves, which depends on such earthquake source parameters as depth, source-type and -orientation, source time function and medium property near the source, is investigated specially with respect to accuracy. The effects of small errors in the solution of the earthquake mechanism and uncertainties of the local underground structure near the source region on the initial phase of surface waves are quantitatively examined on the basis of dislocation theory. By assuming the errors of source parameters and by using different medium models, the errors of the initial phase and surface wave velocity are evaluated. (48 refs.)

110302 Wave magnitudes of the Kurile—Kamchatka tsunamis—Tsunami effect in Japan. T.Hatori (Earthquake Res. Inst., Univ. of Tokyo, Tokyo, Japan).
Bull. Earthquake Res. Inst. Univ. Tokyo (Japan), vol.57, pt.4, p.687-99 (1982).
Based on tide-gauge records of Japan and other far-field data, the magnitudes of the Kurile-Kamchatka tsunamis during the past 77 years (1904-1980) are investigated. The Kamchatka tsunami (April 13, 1923) and the Kurile tsunami (October 20, 1963) are discussed. The magnitudes (Imamura-Iida scale, *m*) of these tsunamis are estimated. The wave heights (above ordinary tides) are considered. In order to predict the travel times of tsunami along the Kurile and Japanese coasts, the refraction diagrams of two imaginary sources are drawn. (25 refs.)

110303 Explosion seismic observation in Izu Peninsula, central Japan. II. Ito-Matsuzaki profile.
Bull. Earthquake Res. Inst. Univ. Tokyo (Japan), vol.57, pt.4, p.701-38 (1982). In Japanese.
For pt.I see ibid., vol.56, no.3, p.484-534 (1981). The second experiment of explosion seismic observations in performed Izu Peninsula, within the Japanese Earthquake Prediction Project, was performed in December 1980 along a profile from Ito to Matsuzaki which obliquely crosses the previous profile from Mishima to Shimoda. Five shot points and about 70 temporary stations were arranged on this profile and an additional shot point was set up at Yumenoshima, Tokyo, about 100 km northeast of the Izu Peninsula. Observations were also made of two other shots at Kawane, Shizuoka Prefecture and Izu Ohshima these were fired by the geological survey of Japan. An outline of the experimental and some fundamental data such as seismograms and travel times are presented. (5 refs.)

110304 Interpretation of a stress profile across the San Andreas fault. M.Bonafede, E.Boschi, M.Dragoni (Dipartimento di Fisica, Univ. di Bologna, Bologna, Italy).
Ann. Geophys. (France), vol.1, no.3, p.195-8 (May-June 1983).
The results of recent stress measurements along the San Andreas fault near Palmdale, California, which show a rapid decrease in shear stress in the proximity of the fault, may be due to the stress drop connected with the great 1857 earthquake, superimposed onto a preseismic ground deformation. This suggestion is made on the basis of a fault model where a preseismic phase of stable sliding at depth is responsible, through stress concentration, for the occurrence of seismic rupture in the upper lithosphere. (18 refs.)

110305 Seismicity pattern before the 1980 Irpinia, Italy, earthquake. P.Suhadolc, G.F.Panza (Istituto di Geodesia e Geofisica, Univ. di Trieste, Trieste, Italy).
Ann. Geophys. (France), vol.1, no.3, p.217-22 (May-June 1983).
Seismicity patterns and precursors before the 23.11.1980 Irpinia, Italy, earthquake are searched for in the ENEL-CNEN Italian earthquake catalogue. By subdividing the region into several seismogenetic areas, some well defined seismicity features are found, which might be taken as precursory to the 1980 event. The space-time seismicity pattern contains features already pointed out as precursory in the literature. By grouping the seismogenetic areas into a seismically homogeneous region, the precursory swarm hypothesis permits prediction of the approximate location where the rupture is bound to occur. (20 refs.)

110306 Single-station Q: attenuation of 2 Hz Rayleigh waves along single isolated propagation paths in Scotland. C.D.Macbeth (Dept. of Geophys., Univ. of Edinburgh, Edinburgh, Scotland), P.W.Burton.
Ann. Geophys. (France), vol.1, no.3, p.223-7 (May-June 1983).
Q_β^{-1} for shear waves in the upper crust of Scotland is determined from fundamental mode. Rayleigh waves of frequency 0.5-5.2 Hz using a single event-station technique. The Rayleigh wave data is obtained from underground and underwater explosions recorded on a linear array and local network respectively. The method maps the Fourier amplitude spectrum recorded along an isolated propagation path to a depth distribution of the specific attenuation factor Q_β^{-1}. (20 refs.)

110307 Effect of topography and subsurface inhomogeneities on seismic SV waves. A.Ohtsuki (Ohsaki Res. Inst., Shimizu Construction Co. Ltd., Tokyo, Japan), K.Harumi.
Earthquake Eng. & Struct. Dyn. (GB), vol.11, no.4, p.441-62 (July-Aug. 1983).
The effect of topography and subsurface inhomogeneity on surface motion is investigated in the case of incident SV waves. Several types of topography, such as a cliff, a cliff with a soft layer and filled land, are considered. Computations are made using a new method combining a particle model with a finite element method. The accuracy of this method is discussed through comparisons with Wong's solutions, which are in good agreement. It is found that the surface displacement is very much influenced by surface irregularities when the incident wavelengths are comparable to the size of the topographic features. Rayleigh waves are strongly produced in the neighbourhoods of the slopes of a cliff and a cliff with a soft layer, the latter being a cliff adjacent to and covered at its foot by a soft layer. Thus, a zone of large amplification takes place near a slope, combining incident SV waves and Rayleigh waves. (31 refs.)

110308 Elliptical anisotropy—its significance and meaning. K.Helbig (Inst. voor Aardwetenschappen, Utrecht, Netherlands).
Geophysics (USA), vol.48, no.7, p.825-32 (July 1983).
Addresses three questions: (1) under what conditions can wavefronts of elastic waves in transversely isotropic media be elliptical?; (2) what are the consequences of elliptical wavefronts for exploration seismics based on surface observations?, and (3) to what degree can an elliptical wavefront be regarded as an approximation of the actual wavefront (in cases where it cannot be truly elliptical)? Another point that will be touched briefly is whether amplitude observations can be used to determine the degree of elliptical anisotropy. (13 refs.)

110309 Numerical study of Love wave propagation. K.R.Kelly (Amoco Production Co., Tulsa, OK, USA).
Geophysics (USA), vol.48, no.7, p.833-53 (July 1983).
Love wave propagation is studied by investigating numerical modeling results for several examples of geologic interest. The modal characteristics of the results are clarified by the use of narrow band-pass filters and two-dimensional Fourier transforms in range and time. Such processing makes it possible to study changes in phase and group velocity for the various modes and to locate points of reflection. This permits one to gain insight into changes in the physical properties of the surface channel supporting the waves. (10 refs.)

110310 Coherent noise in marine seismic data. K.Larner, R.Chambers, M.Yang, W.Lynn, W.Wai (Western Geophys. Co., Houston, TX, USA).
Geophysics (USA), vol.48, no.7, p.854-86 (July 1983).
Despite significant advances in marine streamer design, seismic data are often plagued by coherent noise having approximately linear moveout across stacked sections. With an understanding of the characteristics that distinguish such noise from signal, it is possible to decide which noise-suppression techniques to use and at what stages to apply them in acquisition and processing. Three general mechanisms that might produce such noise patterns on stacked sections are examined: direct and trapped waves that propagate outward from the seismic source, cable motion caused by the tugging action of the boat and tail buoy, and scattered energy from irregularities in the water bottom and sub-bottom. (13 refs.)

110311 Resolution performance of Wiener filters. S.H.Bickel, D.R.Martinez (ARCO Oil & Gas Co., Dallas, TX, USA).
Geophysics (USA), vol.48, no.7, p.887-99 (July 1983).
To improve the resolution of seismic events, one often designs a Wiener inverse filter that optimally (in the least-squares sense) transforms a measured source signature into a spike. When this filter is applied to seismic data, the bandwidth of any noise which is present increases along with the bandwidth of the signal. To reduce signal ambiguity it is common practice to prewhiten the Wiener filter which improves the output signal-to-ambient noise ratio, but at the same time it reduces resolution. The ability to resolve the temporal separation between events is determined by the resolution time constant which the authors define as the ratio of signal energy to peak signal power from the filter. The implications of this definition for unfiltered wavelets and for matched filter signal are discussed. (12 refs.)

110312 Case history of the exploration of the Grand Isle 95 Field in the Gulf of Mexico. P.-H.Pan (Mobil Exploration & Production Services Inc., Dallas, TX, USA).
Geophysics (USA), vol.48, no.7, p.900-9 (July 1983).
Grand Isle 95 Field is located 40 miles offshore Louisiana in 200 ft of water. First stage seismic exploration work was completed by Mobil in 1972. High-amplitude events were observed on the seismic sections which were believed to be related to the existence of hydrocarbons. Reprocessed seismic lines showed some amplitude change near two questionable flat spots which were thought to be the gas-oil and oil-water sand contacts. Careful examination of the original seismic record proved that one of the flat events was caused by noise or distortions under the fault. Subsequent seismic modeling studies led to the success of exploration and exploitation of the field. (2 refs.)

110313 Structural inversion of salt dome flanks. B.T.May (Compass Exploration Inc., Golden, CO, USA), J.D.Covey.
Geophysics (USA), vol.48, no.8, p.1039-50 (Aug. 1983).
Accurate location of the salt-sediment interface is one of the first problems to be solved during exploration around salt domes. However, determination of salt boundaries from seismic data has been notoriously missing even though forward modeling has shown that the salt flank reflection can be one of the highest amplitudes on a seismic record. The sources of difficulty are that conventional data acquisition and processing are usually designed to attenuate any signal that arrives at high incidence angles, including reflections originating from steeply dipping structures such as salt flanks. Inverse modeling by ray methods is known to be a suitable technique for reconstruction of steeply dipping structures, provided key marker reflections are identified. Salt flank reflections have been recovered in two field-recorded examples through application of unusually high stacking velocities; the reflections characteristically have very large migration distances and cross other reflections at high angles. The inverse model computed for one example produced a salt flank with dip rates up to 70 degrees, and the computed structure compared to drilling data is accurate to within 1 percent. (9 refs.)

110314 Computing true amplitude reflections in a laterally inhomogeneous Earth. P.Hubral (Inst. de Geosci., Univ. Faderal da Bahia, Bahia, Brazil).
Geophysics (USA), vol.48, no.8, p.1051-62 (Aug. 1983).
Recently Bortfeld (1982) gave a cursory nonmathematical introduction to a procedure for computing the geometrical spreading factor of a primary zero-offset reflection from the common datum point traveltime measurements of the event. To underline the significance and consequences of this method, a derivation and discussion of geometrical spreading factors is now given for two- and three-dimensional Earth models with curved reflecting boundaries. The spreading factors can be used easily to transform primary reflections in a zero-offset seismic section to true amplitude reflections. These permit an estimation of interface reflection coefficients, either directly or in connection with a true amplitude migration. A seismic section with true amplitude reflections can be described by one physical experiment: the tuned reflector model. Hence the application of the wave equation (in connection with a migration after stack) is justified on such a seismic section. (22 refs.)

110315 Review of elastic and electromagnetic wave propagation in horizontally layered media. B.Ursin (SINTEF, Petroleum Technol. Res. Inst., Trondheim, Norway).
Geophysics (USA), vol.48, no.8, p.1063-81 (Aug. 1983).
Provides a unified treatment of elastic and electromagnetic (EM) wave propagation in horizontally layered media for which the parameters in the partial differential equations are piece-wise continuous functions of only one spatial variable. By applying a combination of Fourier, Laplace, and Bessel transforms to the partial differential equations describing the elastic or EM wave propagation a system of $2n$ linear ordinary differential equations is obtained. The $2n\times 2n$ coefficient matrix is partitioned into 4 $n\times n$ submatrices. By a proper choice of variables, the diagonal submatrices are zero and the off-diagonal submatrices are symmetric. All the results are derived from the symmetry properties of this general equation. It is shown that three-dimensional elastic waves, cylindrical *P-SV* waves, acoustic waves, and electromagnetic waves in isotropic layered media can all be represented by an equation with the same properties. The symmetry properties of the system matrix are used to derive simplified equations for computing the propagator matrix for a stack of inhomogeneous layers. The wave field is also decomposed into upgoing and downgoing waves by an eigenvector decomposition. (56 refs.)

110316 Migration in the presence of a rugged interface with high velocity contrast. L.Ameely, T.Krey, F.Muhtadie, H.-F.Rau, H.Rist.
Geophys. Prospect. (Netherlands), vol.31, no.4, p.561-73 (Aug. 1983).
Three types of migration are presented: (f,x)-time migration with vertical time-to-depth conversion as a second step; Kirchhoff migration down to 0.35 s and Kirchhoff-downward continuation for all times exceeding 0.35 s; and direct depth migration in the (f,x)-domain using three interval velocitiesl. In all cases an intermediate picking of the velocity interfaces is necessary. The results of the second and third migration procedures are superior to those of the first. Possibilities for misinterpretation of faults are reduced considerably when the second or third migration procedure is applied. (6 refs.)

110317 On the principle of maximum entropy and the earthquake frequency-magnitude relation. P.Y.Shen, L.Mansinha (Dept. of Geophys., Univ. of Western Ontario, London, Ontario, Canada).
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.777-85 (Sept. 1983).
The entropy S for a continuous distribution $p(x)$ is defined by $S=-\int_{x1}^{x2}p(x)\ln(p(x)/m(x))dx$, $x_1\leq x\leq x_2$ where $m(x)$ is the 'prior distribution' representing the 'complete ignorance' about x. The difficulty in using this definition arises from the problem of 'arbitrariness' or 'subjectiveness' in assigning the prior distribution $m(x)$. Thus in maximum entropy inference, it is customary to arbitrarily adopt a uniform prior distribution and write the entropy as $S=-\int_{x1}^{x2}p(x)\ln p(x)dx$. This expression, however, is a measure of uncertainty relative to the coordinate x so that the probability distribution $p(x)$ generated from the principle of maximum entropy depends on the choice of x. Only when the chosen parameter actually has a uniform prior distribution, can the generated distribution be expected to conform with the empirical data. For a physical system in which the independent variable x is measured to only limited accuracy, the prior distribution $m(x)$ can be shown to be inversely proportional to the measurement error of x. A parameter with uniform prior distribution, then, is one that can be measured with equal accuracy throughout its range. In this context, the magnitude of an earthquake is such a parameter because using this parameter in the principle of maximum entropy leads to the empirically determined Gutenberg-Richter frequency-magnitude relation. Other proposed frequency-magnitude relations can also be generated from the principle of maximum entropy by imposing appropriate constraints. (34 refs.)

110318 Descriptive statistical model of earthquake source radiation and its application to an estimation of short-period strong motion. A.A.Gusev (Inst. of Volcanology, Petropavlovsk-Kamchatsky, USSR).
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.787-808 (Sept. 1983).
A wide-band source spectrum scaling law is derived from various data sources; its main features are: a lack of similitude and two characteristic frequencies of about 0.2 to 5-10 Hz. An average short-period radiation flux from the source surface does not greatly depend on magnitude; it is about 3×10^7 erg cm^{-2}s and short-period efficiency is about 10 per cent. For sources of great earthquakes a short-period radiation flux is relatively low. The spectrum scaling law is used to determine near-field accelerations. Formulae to estimate 'static' and wavefield accelerations of incoherently radiating sources are derived and applied to calculate the average relation between maximum acceleration and intensity, and distance and magnitude. Theoretical relations agree well with the empirical ones. (58 refs.)

110319 Source parameter inversion of a reservoir-induced seismic sequence: Lake Kariba, Africa (1963 September). G.B.Pavlin, C.A.Langston (Pennsylvania State Univ., University Park, PA, USA).
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.819-41 (Sept. 1983).
The depth and seismic source parameters of the three largest reservoir-induced earthquakes associated with the impoundment of Lake Kariba, Africa, were determined, using a moment tensor formalism of the generalized inverse technique. The events, characterized by $m_b>5.5$, consisted of the foreshock and main event (0640 and 0901 GMT, 1963 September 23) and the principal aftershock (0703 GMT, 1963 September 25). From the analysis of analogue rift valley source crustal models, a three-layer over a half-space model were selected for the analysis of the Lake Kariba events. The epicentral proximity and the comparable source parameters of the three large events suggest a common source fault with an approximate strike of S9°W±4°, dip of $62°\pm 10^D$, and rake of 266°±4°. The Lake Kariba events occurred at depths of less than 10 km. The inferred source parameters, complemented by the structural maps derived from the photo-interpretation of Landsat imagery of the region, indicate a normal fault that uniquely transects the reservoir's deep Sanyati Basin in a north-south heading. (52 refs.)

110320 A hybrid approach to mode conversion. R.Szelwis (Inst. fur Geophys., Univ. Hamburg, Hamburg, Germany).
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.887-904 (Sept. 1983).
Presents a method of investigating seismic surface waves in (two-dimensional) layered media involving lateral heterogeneities. The method combined forward modelling by computation of synthetic seismograms for the distributed layering and subsequent inversion of the seismogram spectra with respect to the wave modes. In terms of 'L region' and 'R region', denoting the laterally homogeneous regions of the waves before and after propagation across the distributed region, the method is described as follows. (1) Analytical definition of the wave in the L region. A time-dependent wavelet is assumed at some surface point, and the spatial displacement field corresponding to a free plane surface wave is computed from the eigenfunctions of the waveguide. (2) Numerical propagation of the wave across the laterally heterogeneous region. The general heterogeneous wave equation is approximated by a finite difference time marching scheme, where the analytical wave motion enters as initial value. (3) Inversion of seismograms 'observed' at a number of locations in the R region. The seismogram Fourier spectra are modelled by a linear combination of modes, contaminated by random noise. Least-squares fitting between the modelled and the observed seismogram spectra yields estimates of the 'mode participation factors'. The method is applied to Love waves of an elastic upper crustal model. (16 refs.)

110321 The effects of initial stress and irregularity on the propagation of SH-waves. M.Chakraborty, A.Chattopadhyay, S.Dey (Dept. of Phys. & Maths., Indian School of Mines, Dhanbad, India).
Indian J. Pure & Appl. Math., vol.14, no.7, p.850-63 (July 1983).
Studies effects on SH-waves due to the presence of initial stresses in a sandwiched layer with parabolic irregularity in the lower interface. The dispersion curves for different values of initial stresses and irregularity of different sizes have been drawn for the fundamental mode and are compared with that for the medium without any initial stress and irregularity. It has been observed that the presence of either the initial compressive stress or the irregularity in the interface has the effect of lowering the phase velocity of the waves, particularly in the low period range. (15 refs.)

110322 The reflection of obliquely incident tsunami. G.F.Carrier, C.F.Noiseux (Div. of Appl. Sci., Harvard Univ., Cambridge, MA, USA).
J. Fluid Mech. (GB), vol.133, p.147-60 (Aug. 1983).
When a tsunami is incident on a plane shelf, the waveform and amplitude of the reflected wave differ significantly from those of the incident wave, and, when the shelf has the extremely irregular character of real continental shelves, the contrast between the two amplitudes is even greater. The authors quantify these statements and they also give an account of the manner in which the run-up depends on the obliquity and on other parameters characterizing the incident wave. (2 refs.)

110323 Gaussian beams and paraxial ray approximation in three-dimensional elastic inhomogeneous media. V.Cerveny (Inst. of Geophys., Charles Univ., Praha, Czechoslovakia), I.Psencik.
J. Geophys. (Germany), vol.53, no.1, p.1-15 (1983).
The elastodynamic Gaussian beams in 3D elastic inhomogeneous media are derived as asymptotic high-frequency one-way solutions of the elastodynamic

equation concentrated close to rays of P and S waves. In this case, the elastodynamic equation is reduced to a parabolic (Schrodinger) equation which further leads to a matrix Riccati equation and the transport equation. The amplitude profile of the principal displacement component of the elastodynamic Gaussian beams is Gaussian in the plane perpendicular to the ray, with its maximum at the ray. As a limiting case of infinitely broad Gaussian beams, the paraxial ray approximation is obtained. (23 refs.)

110324 Wide angle seismic profiling in the ocean using a towed sonobuoy. Yu.P.Neprochnov (Shirshov Inst. of Oceanology, Acad. of Sci., Moscow, USSR).
Oceanology (USA), vol.22, no.2, p.236-8 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
A new method is proposed for seismic profiling in the ocean using a towed sonobuoy and air gun. The distance between the gun and the sonobuoy is selected to provide optimal conditions for tracing the reflecting boundaries, by recording waves reflected in the critical-angle range. On individual legs of the profile it is possible to get the long travel time curves necessary for determining velocity parameters of the medium. Results of tests of this method, done in the Atlantic Ocean on the 24th cruise of the R/V Akademik Kurchatov are presented. (5 refs.)

91.35 EARTH'S INTERIOR STRUCTURE AND PROPERTIES

110325 Geothermal measurements in the upper Euphrates Valley—W Iraq. S.A.AlSinawi, D.S.Mahmood (Dept. of Geology, Univ. of Baghdad, Baghdad, Iraq).
Iraqi J. Sci., vol.23, no.1, p.94-106 (1982). [received: Aug. 1983]
The Hit-Kubaisa area in the upper Euphrates river valley was chosen for a shallow temperature measurement using the GT-2 geophysical thermometer. The area is typified with major faulting and a line of hot springs. An isogeothermal map is constructed after correcting the data for datum date and interpreted qualitatively and quantitatively. A definite relation is established between the springs and the tectonic setting of the area. Depth to groundwater is constructed utilizing thermal data measured near water wells dug in the area. (11 refs.)

110326 Mapping of an unusual crustal discontinuity by microearthquake reflections in the earthquake swarm area near Ashio, northwestern part of Tochigi Prefecture, central Japan. M.Mizoue, I.Nakamura (Earthquake Res. Inst., Univ. of Tokyo, Tokyo, Japan), T.Yokota.
Bull. Earthquake Res. Inst. Univ. Tokyo (Japan), vol.57, pt.4, p.653-85 (1982).
Microearthquake seismograms recorded by the stations in the earthquake swarm area near Ashio on the western border of Tochigi Prefecture, central Japan, frequently have two sharp phases following the direct S-wave. They are identified as near vertical S to P-wave and S to S-wave reflections from an unusual deep crustal discontinuity. Reflection points calculated on the basis of hypocentral coordinates in combination with the travel time data of the reflections are mapped with contour lines at 1 km intervals. The discontinuity is estimated to have a depth of about 14 km beneath Ashio dipping southeastward with considerable local irregularities. It is suggested from the analysis that the discontinuity is underlain by a material of very low rigidity. (16 refs.)

110327 A tear fault system beneath the Atlantis-Meteor seamount group. J.Verhoef, B.J.Collette (Vening Meinesz Lab., Utrecht, Netherlands).
Ann. Geophys. (France), vol.1, no.3, p.199-206 (May-June 1983).
Seismic and magnetic profiling in the area south of the Azores revealed that the Atlantis-Meteor seamount group consists of elongate structures of a typical length of about 100 km in a general NW-SE direction. Plato seamount has slightly different directions. The complex is superimposed on older oceanic crust and partly conceals the fracture zone pattern which otherwise is well developed. The whole area is too shallow compared to the depth-age curve of Sclater. The seamount group can be divided into four subgroups or blocks, together forming a mosaic pattern and suggesting a tear fault system. The blocks underwent extension in a NE-SW direction and are separated by transform zones. This may imply that the volcanism is not due to the presence of a primary mantle hot spot, but that it occurred as a result of a breaking-up of the area, thus creating a secondary hot spot. It is speculated that the cause of the extension must not be sought within the seamount area. (57 refs.)

110328 ^{40}Ar/^{39}Ar age spectrum analysis of detrital microclines from the southern San Joaquin Basin, California: an approach to determining the thermal evolution of sedimentary basins. T.M.Harrison, K.Be (Dept. of Geological Sci., State Univ. of New York, Albany, NY, USA).
Earth & Planet. Sci. Lett. (Netherlands), vol.64, no.2, p.244-56 (Aug. 1983).
Microcline separates from deep drill hole intersections with Eocene to Miocene sediments in the Basin and Tejon Blocks of the southern San Joaquin Valley, California, analysed by the age spectrum approach show radiogenic ^{40}Ar (^{40}Ar*) gradients that record both the slow cooling of the uplifting sediment source ~65 Ma ago, and a recent thermal event. This information, in conjunction with the observation of fission track annealing in the coexisting apatites, allows estimation of the temperature-time conditions of this thermal event at about 140°C for ~200 ka. ^{40}Ar/^{39}Ar analysis of detrital microcline crystals yields thermochronological information in the temperature-time range of petroleum maturation and provides this technique with potential as both a useful exploration tool and as a means of probing the fundamental geodynamic processes of basin evolution. (48 refs.)

110329 The deep structure of ocean ridges in a convecting mantle. G.A.Houseman (Dept. of Geological Sci., Harvard Univ., Cambridge, MA, USA).
Earth & Planet. Sci. Lett. (Netherlands), vol.64, no.2, p.283-94 (Aug. 1983).
A moving ocean ridge which initially is situated on top of a rising sheet in a convecting layer is modelled. The equations are solved numerically to obtain temperature and velocity fields as the ridge moves horizontally. Thus, the evolution of the hot rising sheet can be observed in the temperature and velocity fields as the solution is stepped forward in time. (22 refs.)

110330 Three-dimensional model of the Koyna area of Maharashtra State (India) based on the spectral analysis of aeromagnetic data. J.G.Negi, P.K.Agrawal, K.N.N.Rao (Nat. Geophys. Res. Inst., Hyderabad, India).
Geophysics (USA), vol.48, no.7, p.964-74 (July 1983).
The estimation of thickness of trap rocks in the earthquake-affected Koyna area is an important parameter for revealing the topography that existed before the Deccan volcanism. A case history is presented delineating a three-dimensional block model for the Koyna area by the spectral analysis of aeromagnetic data. The thickness in the area was found to vary from 700 to 2200 m, which correlates well with the results of other geophysical investigations. (24 refs.)

110331 Structure and evolution of the intracratonic basins of central Australia. K.Lambeck (Res. School of Earth Sci., Australian Nat. Univ., Canberra, Australia).
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.843-86 (Sept. 1983).
The central Australian geology is dominated by a series of parallel sedimentary intracratonic basins whose history spans time from the Late Proterozoic to the Carboniferous. The basins are separated by regions of exposed Proterozoic crust that have a history of significant uplift. The formation of the basins cannot be explained by conventional thermal or stretching mechanisms. Nor does the foreland basin model provide an adequate explanation for their occurrence. The geophysical observations, particularly gravity, point to a structure whereby the crust is considerably thicker under the basins than it is under the regions where basement rock is exposed. This suggests that the crust as a whole is involved in the process that led to the basin formation. A mechanical model is developed which is based on the supposition that the lithosphere has been in a state of horizontal compression for long time intervals. The lithosphere is considered as a viscoelastic plate that has been subjected to a small normal load, distributed in an irregular manner. The model is used to explain the structure and evolution of the Officer, Amadeus and Ngalia basins and the Arunta and Musgrave blocks. (70 refs.)

110332 Visco-elastic modelling of lithospheric stresses arising from density contrasts. M.J.M.Park, G.K.Westbrook (Dept. of Geological Sci., Univ. of Durham, Durham, England).
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.905-14 (Sept. 1983).
A method has been developed for application in conjunction with finite element analyis which can be used to model the stress distributions arising from lateral changes in thickness and density of lithospheric layers. It is especially applicable to those situations where there are large lateral variations in density and rock materials are comparatively weak such as the upper crust of active and passive continental margins. The full effect of gravitational body forces is incorporated in a visco-elastic finite element model which is solved within an iterative scheme that preserves the observed or designed shape of the model. If so desired, further deformations can be studied in the 'prestressed' model. To compare the method with others used previously, it was applied to a passive continental margin. (14 refs.)

110333 Pb isotope geochemistry of a massif-type anorthositic-charnockitic body: the Hidra Massif (Rogaland, SW Norway). D.Weis, D.Demaiffe (Univ. Libre de Bruxelles, Brussels, Belgium).
Geochim. & Cosmochim. Acta (GB), vol.47, no.8, p.1405-13 (Aug. 1983).
The Hidra Massif is a massif-type anorthositic-charnockitic body. It consists of undeformed anorthosites and leuconorites, grading into fine-grained jotunites at the contact with the granulite facies gneisses of the metamorphic envelope. A stockwork of charnockitic dykes cross-cuts the massif. The Pb isotopic compositions of the anorthosites and leuconorites are comparable or slightly less radiogenic than those of the jotunites. These values are compatible with an upper mantle origin for the parental magma of jotunitic composition and for the plagioclasic cumulates, but show the incorporation of lower crustal material. The charnockitic dykes have significantly less radiogenic Pb isotope compositions which can be explained by a larger proportion of lower crustal contamination material. The contaminant could be the granulite facies gneisses of the metamorphic envelope. This interpretation is compatible with the K-Rb relationships of these rocks and with the O and Sr isotopic geochemistry. (48 refs.)

110334 Structure of the inner core boundary. D.E.Loper (Geophys. Fluid Dynamics Inst., Florida State Univ., Tallahassee, FL, USA).
Geophys. & Astrophys. Fluid Dyn. (GB), vol.25, no.1-2, p.139-55 (1983).
A model of the inner-core boundary (ICB) is constructed which is consistent with current ideas of the dynamic and thermodynamic state of the core and which is capable of reflecting seismic waves with period of one second. This requires the mass fraction of solid below the ICB to grow to an appreciable fraction in roughly one kilometer. This rapid growth of solid with depth is a result of downward fluid flow from the outer core which is a part of the convective motions which sustain the geodynamo. The solid which crystallizes from this descending fluid after it crosses the ICB continually coats the dendrites which occur there. The gradual cooling of the outer core causes the ICB to advance by growth of dendrites at their tips. The balance of these two effects gives an equilibrium profile for the mass fraction of solid with depth below the ICB which is capable of yielding sharp reflection of seismic waves. (36 refs.)

110335 Isotopes in geothermal energy exploration. E.Barbier, M.Fanelli (Istituto Internat. per le Ricerche Geotermiche, Pisa, Italy), R.Gonfiantini.
Int. At. Energy Agency Bull. (Austria), vol.25, no.2, p.31-6 (June 1983).
Briefly illustrates how geothermal energy arises and the role of isotope investigations in geothermal exploration, just one part of the vast range of isotope applications in hydrology, in geochemistry, and in geology. (no refs.)

110336 On the thermal state of the Earth's mantle. A.C.Fowler (Dept. of Math., MIT, Cambridge, MA, USA).
J. Geophys. (Germany), vol.53, no.1, p.42-51 (1983).
An apparent paradox is discussed, arising from the contrast between an inferred constant mantle viscosity profile and theoretical and experimental rheological flow laws, which predict a mantle viscosity function varying strongly as a function of both temperature and pressure. It is found that the

observed constant viscosity is, in effect, demanded by the interplay of the rheology with the convective process, the mantle temperature is not necessarily adiabatic, and some form of layering effect may be expected. (48 refs.)

110337 Timing, trace and origin of basaltic migration in eastern Australia. F.L.Sutherland (Dept. of Mineralogy & Petrology, Australian Museum, Sydney, Australia).
Nature (GB), vol.305, no.5930, p.123-6 (8 Sept. 1983).
Eastern Australian Cenozoic volcanism includes a prominent southward migration of activity. Varied explanations have invoked hotspot or linear magma sources in the asthenosphere, the movement of Australia over old seafloor spreading zones—with direct or delayed response in volcanism, or changes in stress fields. The present appraisal, using new data, contradicts some ideas and favours volcanism triggered directly by passage of lithosphere over initial sites of Coral Sea spreading. The conclusions suggest that eastern Australia has a major, complex hotspot trail established for the past 65 Myr. It forms an independent and key continental reference to the Hawaiian-Emperor oceanic trail. It raises the notion that both continental and oceanic trails can mark the ghosts of former spreading sites. (51 refs.)

110338 Thermally-activated creep and flexure of the oceanic lithosphere. R.C.Courtney, C.Beaumont (Dept. of Oceanography, Dalhousie Univ., Halifax, Nova Scotia, Canada).
Nature (GB), vol.305, no.5931, p.201-4 (15 Sept. 1983).
Thermal models of the oceanic lithosphere explain ocean floor bathymetry, heat flux and gravity and geoid anomalies by the cooling and thickening of the lithosphere as it ages away from ocean ridges. Surface wave studies tend to confirm that thickness increases with thermal age. Thickness estimates based on the lithosphere's flexural response, parameterized in terms of an elastic model floating on an inviscid substratum, are, however, factors of two to three times less than those from the thermal and seismic models. It is shown that a unification of estimates can be achieved by a different, yet simple, parameterization of the bending response of the lithosphere. (22 refs.)

110339 Possible heterogeneity of the Earth's core deduced from PKIKP travel times. G.Poupinet (IRIGM, Univ. of Grenoble, Grenoble, France), R.Pillet, A.Souriau.
Nature (GB), vol.305, no.5931, p.204-6 (15 Sept. 1983).
Station residuals of the seismic core phase PKIKP have been computed for 400 seismological observatories. PKIKP travel times can be corrected for upper mantle propagation by subtracting P delays; thus PKIKP-P residuals are a measurement of the average vertical travel times in the lower mantle and in the core of the Earth beneath seismic stations. PKIKP-P exhibit a latitudinal dependence: polar stations tend to be faster than equatorial stations. It is shown that this pattern may reflect a departure from spherical symmetry in the P-velocity distribution in the vicinity of the inner core boundary of the Earth. (23 refs.)

110340 BIRPS deep seismic reflection studies of the British Caledonides. J.A.Brewer, D.H.Matthews, M.R.Warner (Dept. of Earth Sci., Univ. of Cambridge, Cambridge, England), J.Hall, D.K.Smythe, R.J.Whittington.
Nature (GB), vol.305, no.5931, p.206-10 (15 Sept. 1983).
The Western Isles-north Channel traverse, an extension of the successful MOIST profile, was recorded in 1982 at sea along the west coast of Britain for BIRPS (British Institutions Reflection Profiling Syndicate) by the Geophysical Company of Norway. The data are of very good quality and contain clear Moho and upper mantle reflections. The lower crust is surprisingly reflective, deeply penetrative thrusts are observed and there is firm evidence that several of the Mesozoic basins round the shores of the United Kingdom were formed by reactivation of older features. (17 refs.)

110341 The relationship between the location of oil and gas provinces and zones of subduction of lithospheric plates. O.G.Sorokhtin, I.Ye.Balanyuk (Shirshov Inst. of Oceanology, Acad. of Sci., Moscow, USSR).
Oceanology (USA), vol.22, no.2, p.169-75 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
The origin of some of the world's largest oil and gas basins (such as those of the Persian Gulf, Venezuela, Algeria, Canada, the Alaskan North Slope, etc.) is considered from the standpoint of the theory of lithospheric plate tectonics. It is shown that most of the basins that are located in pericratonic foredeeps, basins that contain as much as 80% of the world's oil and gas reserves, may have been formed by immigration of hydrocarbons from Recent and old zones of underthrusting of lithospheric plates (subduction zones). The hydrocarbons are generated in these zones via thermolysis or organic matter locked in sediments overriden by island arcs that are thrust over the passive continental margins. This mechanism explains the enormous productivity of the process of oil and gas formation in the subduction zones, compensating for the hydrocarbon losses during their migration into the pericratonic foredeeps. (25 refs.)

110342 A petrographic description of the tholeiitic basalts in the central zone of the Red Sea rift. V.V.Matveyenkov (Shirshov Inst. of Oceanology, Acad. of Sci., Moscow, USSR), A.I.Al'Mukhamedov, G.L.Kashintsev.
Oceanology (USA), vol.22, no.2, p.182-7 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
Petrographic study of the young tholeiitic basalts that form a new oceanic crust in the zone of seafloor spreading in the Red Sea has revealed three generations of phenocrysts. The first generation, consisting of phenocrysts of plagioclase and rare olivine grains, was segregated in a magma chamber at shallow depth. The thorough differentiation of the Red Sea tholeiites is typical of igneous activity in rifts with low rates of spreading. (12 refs.)

110343 Speleothems, travertines, and paleoclimates. G.J.Hennig, R.Grun, K.Brunnacker (Geologisches Inst., Univ. zu Koln, Koln, Germany).
Quaternary Res. (USA), vol.20, no.1, p.1-29 (July 1983).
Age data for about 600 speleothems and about 140 spring-deposited travertines were collected, including many unpublished results. These data were plotted as histograms and also as error-weighted frequency curves on a 350000-yr scale. These plots clearly show periods of increased speleothem/travertine growth as well as times of cessation. The periods of most frequent speleothem growth were between approximately 130000 and 90000 yr ago and since about 15000 yr ago. A comparison with the oxygen-isotope record of deep-sea core V28-238 shows a clear relationship, indicating that terrestrial calcite formation is controlled by paleoclimatic fluctuations. (66 refs.)

110344 Cation-ratio dating: a new rock varnish age-determination technique. R.I.Dorn (Dept. of Geography, Univ. of California, Berkeley, CA, USA).
Quaternary Res. (USA), vol.20, no.1, p.49-73 (July 1983).
Rock varnish coats many surfaces of geomorphic and achaeologic interest in arid lands. The premise of a new age-determination method, cation-ratio dating, is that the ratio of the more mobile cations (e.g. K and Ca) to titanium in varnish decreases with time. Although there are many inherent assumptions and potential limitations, cation-ratio dating has been verified on relative age-sequences from a Death Valley debris cone, Negev Desert talus flatirons, and prehistoric lake levels at Searles Lake in California. Varnish cation ratios have been calibrated to independently dated surfaces in the Coso volcanic field and vicinity in California. (69 refs.)

110345 Quantitative measurement of the mass-color of zircon in igneous rocks from the Kujyu volcanic region, central Kyushu. M.Hayashi, S.Furuya, T.Yamasaki.
Rep. Res. Inst. Ind. Sci. Kyushu Univ. (Japan), no.74, p.39-47 (1983).
The mass-color of zircon contained in igneous rocks of Neogene and Pleistocene ages from the Kujyu volcanic region, central Kyushu, has been quantitatively measured by a color difference meter with the object of clarifying the relation between the mass-color of zircon and the age of formation of the rocks. It has been confirmed that the degree of coloration of zircon gradually increases with the lapse of time after the formation of the rocks. However, there are also a considerable number of exceptions, probably due to unusual concentrations of radioactive elements such as uranium and thorium. (10 refs.)

110346 Fission-track ages of some volcanic rocks from the Kirishima geothermal region. S.Taguchi (Res. Inst. of Industrial Sci., Kyushu Univ., Fukuoka, Japan), M.Okaguchi, T.Yamasaki.
Rep. Res. Inst. Ind. Sci. Kyushu Univ. (Japan), no.74, p.49-54 (1983).
Fission-track dating of five volcanic rocks from the Kirishima geothermal region has been carried out to clarify the stratigraphy of the region. As a result of the dating, it has been revealed that the 'Pliocene' Kakuto Andesites (Mekura, Nanatsudan and Kunimi Lavas) were formed in the Pleistocene, and the Kurinodake Lava and the Kakuto Welded Tuff in the late Pleistocene. The data obtained are as follows: Kakuto Welded Tuff; 9.1×10^4 years; Kurinodake Lava; 1.5×10^5 years; Mekura Lava; 1.1 ± 0.2 Ma; Nanatsudan Lava; 1.2 ± 0.2 Ma; and Kunimi Lava; 1.5×0.3 Ma. (14 refs.)

110347 Geotectonics of some geothermal fields associated with the Quaternary volcanic zone. T.Yamasaki.
Rep. Res. Inst. Ind. Sci. Kyushu Univ. (Japan), no.74, p.55-76 (1983).
In view of its volcanic history and geotectonics, the Kujyu Volcanic district including the Otake area, is most important for standard studies on the geological background of geothermal fields in north central Kyushu. It seems probable that some kind of depressions, such as grabens, fault troughs, and rift zones frequently occur along the crests of warping patterns, and, are closely associated with volcanic activities in most cases. The author discusses the striking similarities which exist between the Otake geothermal field and certain other geothermal fields of the world which are within the Quaternary volcanic zones. 91.40 VOLCANOLOGY

110348 The eruption of Mount Etna, begun on March 28, 1983: its meaning in the framework of the present eruptive cycle (1971-1983). G.Kieffer (Univ. de Clermont II, Clermont-Ferrand, France).
C.R. Seances Acad. Sci. Ser. II (France), vol.296, no.21, p.1689-92 (13 June 1983). In French.
The eruption of Mount Etna in spring 1983 was a typical lateral one. It took place on the 1910 eruption fissural network governed by the magna supply channel at the ESE base of the central core. It confirms the significance of this particular supply channel. It occurs in an exceptionally active eruptive cycle which implies the volcano is in an important stage of deep and dynamic disturbance. (8 refs.)

Nature (GB), vol.304, no.5926, p.527-8 (11 Aug. 1983).
Presents the results of experiments demonstrating that basaltic and dacitic magmas can be easily mixed by forced convection to form both banded dacite and homogeneous andesite in less than a few hours. (18 refs.)

110350 Krakatoa! The decapitation of a volcano. A.Woolley, C.Bishop (Dept. of Mineralogy, Natural History Museum, London, England).
New Sci. (GB), vol.99, no.1372, p.561-7 (25 Aug. 1983).
Discusses the events leading up to and around the 1883 eruption. The mechanism involved is considered together with meteorological aspects. (no refs.)

110351 Geochemical forecast of volcanic eruptions using mercury as an indicator; Mt. Aso. A.Koga.
Rep. Res. Inst. Ind. Sci. Kyushu Univ. (Japan), no.74, p.175-9 (1983). In Japanese.
Continuous determination of mercury is being conducted since May, 1981 on Mt. Aso to forecast its volcanic eruption geochemically. The total amount of mercury captured on the gold needles at the 4 sampling stations around the crater lip appears to correspond to the eruptive manifestations during the collection time. Monitoring of mercury is a superior way of forecasting the volcanic eruption. (6 refs.)

91.45 PHYSICS OF PLATE TECTONICS

110352 The structure of the western margin of the Subalpine Basin (south-eastern France). S.Elmi (Univ. Claude-Bernard, Villeurbanne, France).
C.R. Seances Acad. Sci. Ser. II (France), vol.296, no.20, p.1615-20 (6 June 1983). In French.
Along the ardescian margin, thickness variations of the Triassic-Bathonian series, synsedimentary faults, and sedimentary disturbances, are indicative of a structure network made of tilted blocks limited by NNE, SE and ENE faults. This canvas was a prefiguration of the bending of the Western Alps. (10 refs.)

110353 The Lizard front (Cornwall, England): a main tectonic contact underlain by Paleozoic limestone slices. B.Le Gall, J.Poncet (Univ. de Bretagne Occidentale, Brest, France).
C.R. Seances Acad. Sci. Ser. II (France), vol.296, no.21, p.1683-8 (13 June 1983). In French.
The existence of Paleozoic calcareous tectonic chips pinched under complex amphibolites proves the allochtoneity of the Lizard front. This thrusting tectonic event is related to the 'Bretonian phase' (Upper Devonian). (16 refs.)

110354 Opening of the Red Sea: constraints from a palaeomagnetic study of the As Sarat volcanic field, south-western Saudi Arabia. K.S.Kellogg (US Geological Survey, New York, NY, USA), R.L.Reynolds.
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.649-65 (Sept. 1983).
Four stratigraphic sections through alkali basalt flows of Oligocene to Miocene age (29-24 Ma) in the As Sarat volcanic field, south-western Saudi Arabia, were sampled for palaeomagnetic study. A mean direction of magnetization of $D=355.3°$, $I=15.2°$ ($\alpha_{95}=4.3°$) was found which defines a palaeomagnetic pole at 78.8°N, 247.8°E. Part of one section was apparently erupted during the early phases of a polarity reversal of the Earth's field. The hypothesis of a displaced dipole source for the Earth's field in late Oligocene to early Miocene time is supported by the data. A comparison of the results from As Sarat with palaeomagnetic results from upper Tertiary rocks in Africa indicates that the Red Sea has opened 12° (estimated ±8° at the 95 per cent confidence level). These results indicate that most of the counter-clockwise rotation of Arabia relative to Africa occurred since the eruption of the As Sarat volcanics, in disagreement with proposed models for main-stage Red Sea spreading from late Eocene to early Oligocene time. The palaeomagnetic results also indicate that the Arabian Peninsular was more equatorial in late Oligocene to early Miocene time than it is now. (45 refs.)

110355 Initiation of subsidence in a sedimentary basin underlain by a phase change. J.-C.Mareschal, C.-K.Lee (School of Geophys. Sci., Georgia Inst. of Technol., Atlanta, GA, USA).
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.689-712 (Sept. 1983).
A mechanism of subsidence for axisymmetric sedimentary basins is investigated; it is assumed that the subsidence is caused by the superposition of the motion of a phase boundary and of the flexure of an elastic lithosphere in response to the loading of the Earth's surface by sediment. An approximate solution, describing the motion of the phase boundary when it is subjected to changes in pressure, is used to describe the early stages of the subsidence history of the basin. Several models have been investigated and are presented to demonstrate how the spatial and temporal characteristics of the sediment deposition affect the suggested mechanism. If the basin is wide and the sediment deposition is slow the subsidence can proceed at the same rate or even faster than the sedimentation, resulting in an acceleration of the sediment accumulation. (43 refs.)

110356 Gravity and height variations connected with the recent rifting process in Northern Iceland 1975-1981. W.Torge, E.Kanngieser (Inst. fur Erdmessung, Univ. Hannover, Hannover, Germany).
J. Geophys. (Germany), vol.53, no.1, p.24-33 (1983).
In 1975 rifting started in northern Iceland along the supramarine part of the constructive plate boundary. Regional gravity and height variations have been observed across the neovolcanic zone and the adjoining western and eastern Pleistocene and Tertiary basalt zones. The center of activity is in the Krafla caldera and the rifting has affected the fissure swarm associated with the central volcano. The recent rifting process is characterized by shifting of activity with gravity decrease and uplift at the flanks and gravity increase and subsidence at narrow central parts of the Krafla fissure swarm. (25 refs.)

110357 Tectonics of the Acadian Orogeny in New England and adjacent Canada. D.C.Bradley (Dept. of Geological Sci., State Univ. of New York, Albany, NY, USA).
J. Geol. (USA), vol.91, no.4, p.381-400 (July 1983).
Paleogeographic analysis of Post-Taconian rocks in New England and adjacent parts of Canada has revealed the existence of two volcanic arcs which shut off at the time of the Acadian Orogeny. One was built on arc basement previously accreted to North America during the Taconic Orogeny, the other on Precambrian continental basement of Avalonia. In the intervening Merrimack-Fredericton Trough, metamorphosed and polydeformed turbidites and black shales record deep water conditions in the Silurian. This tract is interpreted as the site of an ocean which closed in the Siluro-Devonian by simultaneous subduction beneath both continental margins. (90 refs.)

110358 Thrusting and duplex formation at Mount Isa, Queensland, Australia. T.H.Bell (Dept. of Geology, James Cook Univ., Queensland, Australia).
Nature (GB), vol.304, no.5926, p.493-7 (11 Aug. 1983).
Large-scale repetition of Mount Isa and Haslingden Group rocks in the anticline north of Mount Isa is interpreted as the core of a thrust duplex which has been subsequently folded parallel to the direction of thrusting. Displacement of Mount Isa Group rocks above the duplex is extremely significant to the regional geology and exploration for more Mount Isa style Pb-Zn and Cu orebodies. Interpretation of the geometry of the thrust belt indicates thrusting on different stratigraphical levels below and above the duplex during its formation, horses formed from a heelwards protruding footwall ridge instead of a trough, and the complex effects on stratigraphical cross-sections through duplexes of sloping lateral footwall ramps on horses. 91.50 MARINE GEOLOGY AND GEOPHYSICS

110359 Composition of pumice layers in Aegean deep-sea sediments and correlation with Minoan eruption. A.Vinci (Inst. of Petrography, Univ. of Parma, Parma, Italy).
Boll. Oceanol. Teor. & Appl. (Italy), vol.1, no.3, p.231-8 (July 1983).
Analyses of pumice clasts from deposits cored within the caldera and outside the island of Santorini (Aegean Sea) reveal a ryodacitic composition and a calcalkaline affinity. Pumices from the cores show some differences in their physical and chemical characteristics. Comparison to the Minoan eruption products allowed to attribute to them only the pumice clasts from outside the caldera. Tephra layers inside the caldera are of uncertain origin, but could be related to the Kaimeni volcanoes. (17 refs.)

110360 Seismic stratigraphy and sedimentation history of the East Mariana Basin, western Pacific. T.H.Shipley, J.M.Whitman (Scripps Instn. of Oceanography, Univ. of California, San Diego, La Jolla, CA, USA), F.K.Duennebier, L.D.Petersen.
Earth & Planet. Sci. Lett. (Netherlands), vol.64, no.2, p.257-75 (Aug. 1983).
Examines seismic reflection and refraction data combined with previous regional synthesis work to describe the seismic stratigraphy and sedimentation

history of this presumably Mesozoic basin. The authors also speculate about the origin of some of the structures observed in the seismic data and as suggested by regional basement depth variations. (29 refs.)

110361 Regional sea level, Southern Oscillation and beach change, New South Wales, Australia. E.Bryant (Dept. of Geography, Wollongong Univ., Wollongong, New South Wales, Australia).
Nature (GB), vol.305, no.5931, p.213-16 (15 Sept. 1983).
The author has studied beach changes for the whole of Stanwell Park beach, New South Wales, Australia, for the period 1895-1980. It is reported that using the average high-tide wave run-up position measured accurate to ±2.5 m from oblique and vertical photographs, changes could be linked to regional sea-level variation and a globally significant climatic variable, the Southern Oscillation. (37 refs.)

110362 On the periglacial regions of the oceans. G.G.Matishov (Murmansk Marine Biology Inst., Acad. of Sci., USSR).
Oceanology (USA), vol.22, no.2, p.176-81 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
Analysis of the latest lithologic and geomorphological data has made it possible to advance and support the concept of the 'oceanic periglacial regions'. This concept encompasses the interrelated phenomena and processes caused by ice sheet glaciations and synchronous with the main stages of their development and degradation, as well as the specific complex of periglacial-marine relief forms of the ocean bottom and the deposits making up these forms, which occupy the ocean floor adjacent to regions of former continental glaciation. The development of periglacial marine formations was determined mainly by two factor—the glacioaquatic discharge that generated underwater glacial-turbidity currents, and iceberg accumulation of morainal material. 91.60 PHYSICAL PROPERTIES OF ROCKS AND MINERALS

110363 Phase relations of amphibole, amphibole-carbonate, and phlogopite-carbonate peridotite: petrologic constraints on the asthenosphere. M.Olafsson, D.H.Eggler (Dept. of Geosci., Pennsylvania State Univ., University Park, PA, USA).
Earth & Planet. Sci. Lett. (Netherlands), vol.64, no.2, p.305-15 (Aug. 1983).
The subsolidus mineralogy and the isobarically-invariant solidus of peridotite in the presence of small amounts of H_2O and CO_2 have been determined from 13.5 to 26 kbar pressure. (47 refs.)

110364 Viscous magnetization of 0.04-100 μm magnetites. D.J.Dunlop (Univ. de Paris VI, St-Maur-des-Fosses, France).
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.667-87 (Sept. 1983).
Acquisition and decay of small-field viscous magnetization have been measured as a function of temperature (9-500°C) for four synthetic magnetite dispersions ranging in a mean particle size from 0.04 to 0.22 μm and at room temperature only for an additional six samples (2-100 μm). Room-temperature viscous magnetization is pronounced in the single-domain range, slight between 0.1 and 5 μm, and again substantial in the intermediate multi-domain range (10-15 μm). In all experiments, the acquisition rate exceeded the decay rate, resulting in residual undecayed viscous remanent magnetization (VRM) after a zero-field decay time equal to the time of exposure to a field. Viscous magnetization is enhanced at elevated temperatures but not in direct proportion to absolute temperature. VRM produced isothermally at a given temperature is significantly more difficult to erase by heating to a higher temperature than most thermal activation theories predict. The implications of these observations are that viscous overprinting of natural remanent magnetization in magnetite-bearing rocks, particularly during burial or intrusive reheating, may be more extensive and more difficult to erase then previously believed. (49 refs.)

110365 Pore structure of hydrothermally altered rocks in the Otake geothermal area. K.Gotoh, S.Kawano, N.Takada.
Rep. Res. Inst. Ind. Sci. Kyushu Univ. (Japan), no.74, p.7-16 (1983). In Japanese.
Pore structure of hydrothermally altered rocks in the Otake geothermal area is measured by mercury-intrusion measurements. The pore-size distribution curves show some characteristics and correspond to the alteration degree and alteration ratio proposed by Hayashi. The permeability of the altered rocks is 10-100 times greater than that of the unaltered rocks. (4 refs.)

110366 Rock magnetism. P.N.Shive (Dept. of Geology & Geophys., Univ. of Wyoming, Laramie, WY, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.665-71 (April 1983).
Discusses igneous rocks, thermoremanent magnetisation, sediments, detrital remanent magnetisation, anisotropy, stress, rotational remanent magnetisation, instrumentation, techniques and data analysis. (120 refs.)

91.65 GEOPHYSICAL ASPECTS OF GEOLOGY, MINERALOGY AND PETROLOGY

110367 Automatic three-layer, three-dimensional deconvolution of the Pays de Bray anticline. E.Alessandrello, M.Bichara, J.Lakshmanan (Compagnie de Prospection Geophys. Francaise, Rueil-Malmaison, France).
Geophys. Prospect. (Netherlands), vol.31, no.4, p.608-26 (Aug. 1983).
Gravity data have been transformed into a three-layer, three-dimensional model by using an automatic procedure based on linear filtering. The Bouguer anomaly is first transformed by linear filtering into density variations located between two planes 1100 and 2500 m deep. These densities are then transformed into thicknesses with a constant density contrast of 0.4 g/cm^3 with two geological constraints for the second and third interface. Differences between measured and computed gravity are then applied by a similar procedure to a layer located between depths of 0 and 500 m. (9 refs.)

110368 Origin of the Ilmenogorsk-Vishnevogorsk nepheline syenites, Urals, USSR, and their time of emplacement during the history of the Ural fold belt: a Rb-Sr study. U.Kramm (Inst. for Mineralogy, Univ. of Munster, Munster, Germany), A.B.Blaxland, V.A.Kononova, B.Grauert.
J. Geol. (USA), vol.91, no.4, p.427-35 (July 1983).
Miaskitic nepheline syenites of the Ilmenogorsk-Vishnevogorsk Alkaline Complex in the Ural Mountains were emplaced approximately 450 Ma ago, as indicated by Rb-Sr whole rock ages. Their intrusion coincided with a dilatation period along the eastern margin of the Russian platform, and predated the compressive stage of the Hercynian orogeny in the Urals which began during the Silurian. Internal mineral isochrons for two nepheline syenites and an alkali-feldspar syenite from different regions of the complex yield consistent Permian ages of 245 Ma. These ages are interpreted as dating the cooling of the alkaline rocks after a final amphibolite grade Hercynian metamorphism. (29 refs.)

110369 An oscillating trend in Phanerozoic non-skeletal carbonate mineralogy. P.A.Sandberg (Dept. of Geology, Univ. of Illinois, IL, USA).
Nature (GB), vol.305, no.5929, p.19-22 (1 Sept. 1983).
Textural and compositional data on ancient ooids and cements suggest the existence of an oscillating Phanerozoic temporal trend in non-skeletal mineralogy. The trend shows good correlation with eustatic-climatic oscillations proposed by others. The most likely mechanism appears to be plate-tectonically influenced oscillation in the vapour pressure of CO_2 rather than change in oceanic Mg/Ca ratio. (45 refs.)

110370 Permian alkaline undersaturated and carbonatite province, and rifting along the West African craton. J.P.Liegeois (Musee Royal de l'Afrique Centrale, Tervuren, Belgium), H.Bertrand, R.Black, R.Caby, J.Fabre.
Nature (GB), vol.305, no.5929, p.42-3 (1 Sept. 1983).
Reports that a Permian radiometric age obtained for an intrusion shows the existence of a hitherto unsuspected important tectono-magmatic event in this part of Africa, which may have far-reaching structural implications as well as economic interest. (12 refs.)

110371 Major southward thrusting of the Dalradian rocks of Connemara, western Ireland. B.E.Leake, P.W.G.Tanner, D.Singh (Dept. of Geology, Univ. of Glasgow, Glasgow, Scotland), A.N.Halliday.
Nature (GB), vol.305, no.5931, p.210-13 (15 Sept. 1983).
The authors propose a model for the Connemara Dalradian, that of an allochthonous thrust sheet, which highlights hitherto unsuspected similarities between the tectonic histories of the south-east margins of the metamorphic Caledonides in the British Isles and Scandinavia. (28 refs.)

91.90 OTHER TOPICS IN SOLID EARTH GEOPHYSICS

110372 Multispectral remote sensing of saline seeps. L.Chaturvedi, K.R.Carver (New Mexico State Univ., Las Cruces, NM, USA), J.C.Harlan, G.D.Hancock, F.V.Small, K.J.Dalstead.
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.239-51 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
An aircraft experiment was conducted in early summer of 1981 to determine the feasibility of optical and microwave remote sensing techniques for the detection of fully developed and incipient saline seeps in South Dakota and Montana. The NASA C-130 Earth resources aircraft was used to acquire *L*-band and *C*-band scatterometer data (backscattering coefficient profiles), radiometer data (brightness temperature profiles), and color-infrared photography; additional passive microwave data and thermal images were acquired. Intensive soil moisture and salinity data were collected on a uniform 20-m grid spacing and at several depths for the 600×600 m South Dakota site. The two Montana sites were over-flown with flight lines several kilometers in length, and ground truth information was obtained by identifying known geological and geohydrological units with varying soil salinities on a regional basis. In summary, the 1981 data set disclosed no reliable means of remotely sensing potential saline seeps. (7 refs.)

110373 Effects of a rough boundary surface on polarization of the scattered field from an inhomogeneous medium. A.K.Fung, H.J.Eom (Remote Sensing Lab., Univ. of Kansas Center for Res. Inc., Lawrence, KS, USA).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.265-70 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
The effect of surface roughness on the polarization of the microwave scattered field is studied by combining the standard Kirchhoff method for rough surface scattering with the radiative transfer method for volume scattering using the Rayleigh phase function. Corresponding cases of pure surface scattering from a homogeneous layer and volume scattering from a plane inhomogeneous layer are also computed to serve as points of reference. In each case the degree of polarization *DP*, polarization ratio *PR*, locations on the Poincare sphere of copolarization nulls *CN*, and cross-polarization nulls *XN* are computed. It is found that for pure surface scattering *PR* between 0-20° incidence angles is quite sensitive to change in surface roughness. (19 refs.)

110374 Comparison of multifrequency band radars for crop classification. A.J.Sieber (Inst. for Radiofrequency Technol., Deutsche Forschungs- und Versuchsanstalt fur Luft- und Raumfahrt e.V., Oberpfaffenhofen, Germany).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.285-94 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
A first, systematic experiment with airborne SAR systems working in *X*-, *C*-, and *L*-band took place during the European Convair SAR 580 experiment in 1981. One major topic of the use of SAR images is to analyse their potential for agricultural applications including crop identification. This paper describes results from the analysis of images taken over two German test sites. These data prove that differences of the backscattering behavior of crops are mainly related to the dielectric geometry of the plants. The paper will give examples. Furthermore, the data analysis undertaken on the base of SAR 580 data will be described. (9 refs.)

110375 Method for retrieving the true backscattering coefficient from measurements with a real antenna. F.T.Ulaby, C.T.Allen, A.K.Fung (Remote Sensing Lab., Univ. of Kansas Center for Res., Inc., Lawrence, KS, USA).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.308-13 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
Measurements made of the power backscattered by a surface at angles near normal incidence include contributions due to both coherent and incoherent scattering. Additionally, these contributions are weighted by the antenna pattern. Using a theoretical model to describe the backscattering from a rough soil surface, a procedure is developed for retrieving the true angular pattern of the backscattering coefficient σ^0 from measured estimates of σ^0, where the measured estimate is based on the usual assumption that σ^0 is approximately constant over the angular extent of the antenna beam for narrow-beam systems. The retrieved patterns of σ^0 were then used to evaluate the dependence of σ^0 on soil surface roughness at 1.5, 4.25, and 7.25 GHz. (10 refs.)

110376 Classification of agricultural crops in radar images. P.Hoogeboom (Phys. Lab. TNO, The Hague, Netherlands).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.329-36 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
For the past few years an accurate X-band SLAR system with digital recording has been available in The Netherlands. The images of this system are corrected to indicate radar backscatter coefficients (gamma) instead of arbitrary greytones. In 1980 a radar measurement campaign was organized in the Flevopolder area. Ground-based measurements were carried out and at certain prefixed times flights were made. The optimum flight times had been derived from a simulation study, based on previous measurements. The results of this campaign are now being analyzed. The one-dimensional case, consisting of one flight over the test area at a previously derived optimum flight time gives only 35-percent correct classification in 7 classes. Multidimensional cases with flights at different dates improve the classification result to over 85-percent. The small differences in backscatter between the various types of crops clearly demonstrate the need for an accurate radar system which does not show too much speckle. (8 refs.)

110377 Computer simulation of speckle in a synthetic aperture radar image pixel. K.Tomiyasu (General Electric Co., Valley Forge Space Center, Philadelphia, PA, USA).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.357-63 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
Images of a uniform scene produced with a synthetic aperture radar will frequently appear nonuniform. This phenomenon, called 'speckle', is attributed to the coherency of the radar signal and intrapixel interferometry. Speckle is generally regarded as image contrast or response variation between adjacent pixels of a uniform scene. The same type of variation can be observed by imaging just one such pixel when viewed from different azimuthal heading angles. A computer program described in this paper was written to simulate the radar return from a single pixel containing numerous scatterers. The phase and amplitude of the signal reflected from the pixel generally varies from pulse to pulse due to intrapixel interference. After integration, the pixel response usually differs with each 'azimuth look', and this speckle variation between azimuth looks may be as much as 20 dB or more. Speckle variation can be significantly reduced by averaging or median filtering multiple azimuth looks per pixel. (22 refs.)

110378 Application possibilities of passive remote-sensing systems in the millimeter-wave region. K.Gruner, W.Keydel, H.Suss (DFVLR, Inst. fur Hochfrequenztechnik, Oberpfaffenhofen, Germany).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.376-82 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
This presentation gives, after a discussion of advantages and disadvantages of microwave radiometry and a short reference to the state of the art, several application possibilities based on airborne DFVLR measurements at 32 and 90 GHz: Earth observation with respect to vegetation conditions, ground moisture, and snow cover; traffic control at land and sea and sensing of road conditions; and Earth observation during bad ground visibility. An outlook to expectable future developments will be given on the basis of present requirements. Main goals are the increase of data rates as well as geometrical and temperature resolution improvements by use of multireceiver systems in order to get operational microwave radiometry systems for remote sensing. (3 refs.)

110379 Radar backscattering properties of corn and soybeans at frequencies of 1.6, 4.75, and 13.3 GHz. J.F.Paris (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.392-400 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
An observational study was made of the radar-backscattering properties of corn and soybeans in commercial fields in a test site in Webster County, Iowa. Aircraft-based radar scatterometers measured the backscattering coefficient of the crops at three frequencies, 1.6 GHz (*L*-band), 4.75 GHz (*C*-band), and 13.3 GHz (*Ku*-band), at 10 sensor look-angles (5 to 50 degrees from the nadir in steps of 5 degrees), and with several polarization combinations. They produced 50 combinations of frequency, look-angle, and polarization for analysis for about 80 fields on two flight dates. Based on these data, the investigator reached conclusions concerning the influences of crop row direction, row-direction differences and soil moisture on the discrimination of these two crops by radar techniques. (21 refs.)

110380 Scattering from randomly oriented circular discs with application to vegetation. M.A.Karam, A.K.Fung (Remote Sensing Lab., Univ. of Kansas Center for Res., Inc., Lawrence, KS, USA).
Radio Sci. (USA), vol.18, no.4, p.557-65 (July-Aug. 1983).
A vegetation layer is modeled by a collection of randomly oriented circular discs over a half space. The backscattering coefficient from such a half space is computed using the radiative transfer theory. Comparisons are shown with measurements taken from milo, corn and wheat and good agreements are obtained for both polarized and cross-polarized returns. (15 refs.)

110381 Shadowing by non-Gaussian rough surfaces for which decorrelation implies statistical independence. E.Bahar, M.A.Fitzwater (Electrical Engng. Dept., Univ. of Nebraska, Lincoln, NE, USA).
Radio Sci. (USA), vol.18, no.4, p.566-72 (July-Aug. 1983).
Expressions for the shadow functions are derived for a broad class of non-Gaussian rough surfaces. The numerical results obtained for the backscatter shadow functions are compared with an exponential joint height probability density that does not become statistically independent as the surface heights decorrelate. (12 refs.)

110382 Model for atmospheric corrections to microwave brightness temperature data. K.S.Rao, Y.V.S.Murthy (Centre of Studies in Resources Engng., Indian Inst. of Technol., Bombay, India), A.K.S.Gopalan, R.Ramakrishnan, T.J.Majumdar.
Remote Sensing Environ. (USA), vol.13, no.3, p.209-32 (July 1983).
The effects of atmospheric liquid water (cloud) and water vapor on the brightness temperature data acquired by Bhaskara-Satellite Microwave Radiometer at 19.1 and 22.235 GHz near the nadir look angle have been discussed in detail. It has been observed that the net contribution to brightness temperature data due to the atmosphere is quite considerable over sea and wet land conditions. Two operational quasistatistical models have been developed for doing atmospheric corrections to brightness temperature data, one applicable under cloud-free conditions and the other under all weather conditions. The physical concept to arrive at these quasistatistical models have been discussed. The constants of the models are estimated by the method of least squares fit by simulating 200 sets of atmospheric and ground conditions. (20 refs.)

110383 Multiple microtektite horizons in Upper Eocene marine sediments: no evidence for mass extinctions. G.Keller (US Geological Survey, Menlo Park, CA, USA), S.D'Hondt, T.L.Vallier.
Science (USA), vol.221, no.4606, p.150-2 (8 July 1983).
Microtektites have been recovered from three horizons in eight Middle Eocene to Middle Oligocene marine sediment sequences. Five of these occurrences are coeval and of latest Eocene age (37.5 to 38.0 million years ago) ; three are coeval and of early Late Eocene age (38.5 to 39.5 million years ago) : and three are of middle Oligocene age (31 to 32 million years ago) . In addition, rare probable microtecktites have been found in sediments with ages of about 36.0 to 36.5 million years. The microtektite horizon at 37.5 to 38.0 million years can be correlated with the North American tektite-strewn field, which has a fission track age (minimum) of 34 to 35 million years and a paleomagnetic age of 37.5 to 38.0 million years. There is no evidence for mass faunal extinctions at any of the microtektite horizons. (20 refs.)

110384 Correction for low Sun elevation in Landsat imagery. M.Piacentini (Dipartimento di Elettronica, Politecnico di Milano, Milano, Italy).
Signal Process. (Netherlands), vol.5, no.4, p.311-18 (July 1983).
The use of Landsat images of mountainous areas to extract the texture of the terrain poses some unique problems, due to the Sun illumination. The author develops a simple but effective model which shows that the whole process is equivalent to a linear space invariant filtering, at least in its general effects. This equivalence, confirmed by experimental results, is utilized to develop an inverse filter. The author also reports, as an example, the effects of the illumination and of its correction on an algorithm which finds the local principal direction of the structure of the terrain, showing the interesting improvements in performances that can be obtained. The conclusions are not restricted to the Landsat images only, but can be extended to any aerial or satellite image of the mountainous areas. (2 refs.)

110385 Low frequency variability in the Mediterranean Outflow west of Gibraltar. B.R.Stanton (Inst. of Oceanographic Sci., Wormley, England).
Deep-Sea Res. Part A (GB), vol.30, no.7A, p.743-61 (July 1983).
Low frequency variability in the Mediterranean Outflow was studied using three current meter moorings set to the west of the Strait of Gibraltar in 1974 and 1976 to 1977. At low frequencies (period greater than 2 days) temperature and velocity were highly coherent in the transition layer above the outflow core and temperature fluctuations were carried with the outflow. While no significant series correlations are found between mooring data and meteorological data from Gibraltar, the largest fluctuations in the outflow were associated with extreme meteorological conditions. The forcing of the events is examined. Wind stress forcing gives results that contradict previous findings, while the barotropic response of the flow through the straits to rapid changes in barometric pressure is a likely mechanism in some instances. (18 refs.)

110386 Mesoscale rings in an ocean with vertical shear. M.Ikeda (Dept. of Oceanography. Univ. of British Columbia, Vancouver, BC, USA).
Deep-Sea Res. Part A (GB), vol.30, no.7A, p.783-99 (July 1983).
Movement and evolution of mesoscale rings in an ocean with vertical shear are studied using a two-layer quasi-geostrophic, inviscid model on a β plane. Initially an isolated ring is assumed to have motion only in the upper layer, which is otherwise quiet. The vertical shear is represented by a uniformal zonal flow in the lower layer. The results are applied to rings drifting in recirculating gyres associated with the Gulf Stream, where the upper layers are westward-flowing relative to the lower layers. Waves generated in the flows are discussed. (11 refs.)

110387 An investigation of summer sea surface temperature anomalies in the eastern North Pacific Ocean. J.R.Lanzante, R.P.Harnack (Dept. of Meteorology & Phys. Oceanography, State Univ. of New Jersey, New Brunswick, NJ, USA).
Tellus Ser. A (Sweden), vol.35a, no.4, p.256-68 (Aug. 1983).
A study of summer sea surface temperature anomalies in the eastern North Pacific Ocean is undertaken to examine some of the processes that could affect their evolution and which may be important for their prediction. An empirical approach is utilized. The factors considered include sea surface temperature (SST) persistence, oceanic thermal advection, and wind mixing. The primary variable studied is the summer SST anomaly for each of 25, 5° latitude by 10° longitude boxes in the region 140°W-170°E, 30-55°N. Thirty years of data is used (1947-76). Diagnostic analyses using data from four Ocean Weather Stations (C, D, P and V) are performed prior to the analyses described above in order to examine wind mixing more closely. The monthly mean SLP gradient is used as an estimate of average monthly wind speed over the 25 box domain where measured winds are not routinely available. In addition, winds derived from daily sea level pressure (SLP) analyses are averaged to form monthly means. The box-averaged data are employed to specify the summer SST from the components of the total horizontal thermal advection. (29 refs.)

110388 Ocean response to mesoscale atmospheric forcing. I.Orlanski, L.J.Polinsky (Geophys. Fluid Dynamics Lab./NOAA, Princeton Univ., Princeton, NJ, USA).
Tellus Ser. A (Sweden), vol.35a, no.4, p.296-323 (Aug. 1983).
Many processes have been proposed as possible forcing mechanisms for mesoscale oceanic variability. The authors show that atmospheric forcing can be an important source of mesoscale variability in the ocean and that the response is linearly proportional to the product of the time scale of the storm and its intensity. The authors clarify the point that for storms with scales considerably smaller than the barotropic Rossby radius of deformation, the oceanic stratification and the horizontal extent of the storm are the only factors determining the penetration depth of the response, implying that it is not the Rossby radius of deformation but rather the scale of penetration depth ($h=(f/N)L$) that characterizes the response. The role of the mixed layer is considered very important in the transfer of surface stresses down into the system. (19 refs.)

110389 On the existence of some periodicities in the long fluctuations of the sea level. S.Fais (Osservatorio Geofisico Sperimentale, Trieste, Italy), F.Mosetti.
Boll. Oceanol. Teor. & Appl. (Italy), vol.1, no.3, p.175-85 (July 1983).
Analyses the periodicities in three sea level series, relative to the Brest, Swinoujscie and Venice marigraphic stations. The spectral analysis of the sea level record carried out by Fast Fourier Transform and Maximum Entropy Method techniques shows various periodical components for the long period sea level fluctuations. Many of the components found are common to the three examined series and, as it results from previous studies, they are in accordance with some of the periodicities characterizing a lot of natural oscillating phenomena, particularly the climatic and geophysical ones. Therefore, it can be considered that both the natural oscillating phenomena and the long period sea level fluctuations in any locality are ruled by a mean common law, that influences their temporal evolution. The authors present the results of some spectral analyses with the relative periodicities component of the above-mentioned law. (17 refs.)

110390 Water continuity or salt continuity: an actual problem for the matter budget of the sea through the straits. F.Mosetti (Istituto di Geodesia e Geofisica, Univ. di Trieste, Trieste, Italy).
Boll. Oceanol. Teor. & Appl. (Italy), vol.1, no.3, p.225-9 (July 1983).
Discusses solving the dynamic method for computing the currents acting through a strait. For such a purpose some conditions on the continuity are considered. Only by means of such a condition can the relative values of velocity, given with the dynamic method, be transformed into absolute values. The discussion concerns the choice of the condition of continuity of the water or the one of the salt. Both the conditions are characteristic of the hydrological conditions considering the role of the evaporation. (no refs.)

110391 The vertical structure annual cycle of the mass field parameters in the Gulf of Trieste. F.Stravisi (Istituto Talassografico di Trieste, Trieste, Italy).
Boll. Oceanol. Teor. & Appl. (Italy), vol.1, no.3, p.239-50 (July 1983).
Vertical CT and velocity profiles have been measured in the Gulf of Trieste over a three year period. The temperature, salinity and density data every meter depth are analyzed by means of a cosine least squares fitting procedure, using two waves of annual and semi-annual period respectively. The smooth depth dependence of the computed mean values, wave amplitudes and phases proves the efficiency of the method even in the case of few data not equally distributed in time. The time depth t, S, ρ histories through the year are examined. The mean velocity field as a function of depth shows a surface layer with a strong shear and a bottom layer flowing in opposite directions. (9 refs.)

110392 Waves and circulation driven by oscillatory winds in an idealised ocean basin. D.B.Haidvogel, P.B.Rhines (Woods Hole Oceanographic Instn., Woods Hole, MA, USA).
Geophys. & Astrophys. Fluid Dyn. (GB), vol.25, no.1-2, p.1-63 (1983).
Examines via direct numerical integration, the transient and rectified response of a flat-bottomed barotropic ocean to a spatially localised oscillatory wind-stress pattern. The experiments exemplify in many respects the dynamics which drive the deep motion in recent eddy-resolving ocean circulation studies [e.g. Holland and Rhines (1980)], and may be contrasted with the results of Pedlosky (1965) and Veronis (1966) for spatially broad, time-dependent forcing. By considering doubly re-entrant (periodic) and closed basin geometries, the structure and magnitude of the induced circulation is shown to depend most critically on the form of the mean quasi-geostrophic contours. (23 refs.)

110393 Linear stability and stable modes of geostrophic fronts. N.Paldor (Dept. of Isotope Res., Wiezmann Inst. of Sci., Rehovot, Israel).
Geophys. & Astrophys. Fluid Dyn. (GB), vol.24, no.4, p.299-326 (1983).
A Rayleigh integral is used to prove that an unbounded geostrophic front of uniform potential vorticity is stable with respect to small perturbations of arbitrary wavelength. The ageostrophic theory developed in this study yields a stable, near-inertial, long trapped mode. Recent oceanic observations of the increase in the energy of the inertial peak in the vicinity of fronts support the existence of this inertial trapped mode. In addition the theory yields a geostrophic mode which is expected to become unstable when the potential vorticity is not uniform. (26 refs.)

110394 Long-wave instability of an isolated front. P.D.Killworth (Dept. of Appl. Math. & Theoretical Phys., Univ. of Cambridge, Cambridge, England).
Geophys. & Astrophys. Fluid Dyn. (GB), vol.25, no.4, p.235-58 (1983).
The stability of an isolated one-layer reduced gravity front is examined. It is shown that the system is unstable to long-wave disturbances provided merely that a simple condition on the depth profile is satisfied far from the front. The instability does not require the extremum of potential vorticity needed by quasi-geostrophic theory. The instability releases mean kinetic and mean potential energy from the system, but lacking a second layer cannot truly be termed baroclinic instability. (8 refs.)

110395 Benthic fronts and global excess radon distribution. C.Lambert (Lab. Mixte, CNRS-CEA, Gif-sur-Yvette, France), P.Linden, D.Lowenthal, M.Stern.
Geophys. & Astrophys. Fluid Dyn. (GB), vol.25, no.4, p.309-15 (1983).
GEOSECS measurements of excess radon 222 as a function of depth above the sediments in the Atlantic and Pacific are sufficient to resolve the median profile in each ocean, but not the mean profile. The transport process maintaining the oceanic means is highly intermittent, and is not consistent with mixing by small scale turbulence generated at the ocean bottom. The authors suggest that transport of radon above the benthic boundary layer is driven by isopycnal motions associated with baroclinic instabilities on benthic fronts. A method for generating benthic fronts together with the subsequent instabilities is demonstratted in the laboratory. (7 refs.)

110396 Gravity wave propagation at randomly inhomogeneous nonstationary currents. M.A.Raevskii.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.6, p.639-45 (June 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
Closed equations have been obtained for the average field and average intensity of gravity waves propagating at the current whose velocity is a random function of coordinates and time. Scattering of gravity waves by large scale near-surface turbulence and random internal waves is considered on the basis of these equations. In particular, it is shown that the average energy of gravity waves increases monotonously at the scattering. Estimates have been obtained for the characteristic time of the average field damping, the angular spectrum variation and the energy of the waves. (3 refs.)

110397 A model for transformation of nonlinear baroclinic vortex in open ocean. Yu.A.Ivanov, V.I.Kuzin.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.6, p.646-52 (June 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
The transformation of a model vortex in a constant-depth baroclinic ocean is studied. Initially, a baroclinic vortex is specified, then it is modified as a solution of a differential equation that is an equation of conservation of a planetary vortex to a geostrophic approximation. The problem is solved numerically by the finite element method. Comparison of the results is made, when nonlinearity is taken into account and when it is not. (3 refs.)

110398 On the character of the variability of the semi-diurnal velocity oscillations in the ocean. K.I.Chigrakov.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.7, p.716-23 (July 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
The temporal variability of the oceanic semi-diurnal velocity oscillations is considered. The algorithms of the comparatively narrow-band filter for extraction of these oscillations from vector time series are presented. Several examples of the strong difference of the semi-diurnal oscillations observed at close places and examples of the great variability of these oscillations during one or two periods are presented. (13 refs.)

110399 Thermal influence of submerged buoyant jet on sea ice cover. V.V.Bogorodskii, K.K.Sukhorukov.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.7, p.724-9 (July 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
Presents studies of free artificial thermal convection from a submerged axisymmetrical concentrated source. The thermal and kinematical structure of the rising jet is studied under conditions of a homogeneous and stably stratified environment with the ice cover on the surface. An analytical description

of mean temperature and vertical velocity fields is presented for the free jet in a homogeneous environment and the internal structure of turbulence near the axis is studied. The efficiency of the thermal influence of the free jet on the ice cover from below is discussed and formulae are suggested for the calculation of the heat flux in the melting zone with dependence on the power and depth of the source. (5 refs.)

110400 On calculation of vertical velocity in models of sea currents. A.S.Sarkisyan, Yu.L.Dyomin, D.I.Trukhchev.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.7, p.730-40 (July 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
Some methods for the calculation of the vertical velocity field in numerical models of sea currents are discussed. The results obtained with quasigeostrophic and nonlinear (primitive equation) models are compared. A few methods for the calculation of the vertical velocity field are used in both models. Some causes of errors arising in determining the vertical velocity are discussed. (12 refs.)

110401 On interactions of synoptic scale eddies in the open ocean. D.G.Seidov, I.G.Yushina.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.7, p.750-60 (July 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
The evolution of the barotropic mode for the motion of several idealized currents in the open ocean is studied using a numerical model. Interactions between the individual eddies, between eddies and jets, and instability of jets produced by turbulent fluctuations are simulated. It is shown that the joint effect of nonlinear interaction and differential rotation leads to complicated dynamics with some sinergism in the field of synoptic scale currents. (8 refs.)

110402 Comparative study of some heat balance parameters in the Bay of Bengal and the Arabian Sea. G.R.Lakshmana Rao, K.Sivanagi Reddy (Dept. of Meteorology & Oceanography, Andhra Univ., Waltair, India).
Indian J. Mar. Sci., vol.12, no.1, p.43-4 (March 1983). [received: Sept. 1983]
Annual variations of net radiation, total energy transfer, surplus energy and sea surface temperature of 2 stations (17°N, 61°E and 17°N, 69°E) in the Arabian Sea and 1 station (17°N, 87°E) in the Bay of Bengal are compared. Net radiation maximum is observed in April and minimum in December at all stations. At the station in the Bay of Bengal the total energy flux from the sea surface is more during winter than during SW monsoon period, whereas in the Arabian Sea stations it is reverse. During winter the Bay of Bengal station shows more energy deficit than the other 2 stations. The sea surface temperature follows the trend of the surplus energy, lagging behind by nearly a month. (6 refs.)

110403 Mesoscale oceanographic features associated with the central Bering Sea ice edge: February-March 1981. R.D.Muench (Sci. Applications Inc., Bellevue, WA, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2715-22 (30 March 1983). [received: Sept. 1983]
Midwinter 1981 observations from the central Bering Sea shelf showed a hydrographic structure which was two layered in temperature, salinity, and density. This structure was confined to a 100-km-wide band which coincided approximately with the ice edge. The colder, lower-salinity upper layer was continuous in its *T-S* properties with homogeneous water to the north beneath the ice. The warmer, more saline lower layer was similarly continuous with water to the south near the shelf break. A northwestward baroclinic flow of the surface relative to 75 dbar was associated with the layered structure. The layered structure and associated flow appear to be regular winter features associated with the ice edge in this region. Input of low-salinity water from melting of ice along the edge is adequate to maintain the layered structure, and its associated baroclinic circulation, against the effects of tidal and wind mixing. (21 refs.)

110404 Effects of a shelf polynya on flow and water properties in the northern Bering Sea. J.D.Schumacher (Pacific Marine Environmental Lab./NOAA, Seattle, WA, USA), K.Aagaard, C.H.Pease, R.B.Tripp.
J. Geophys. Res. (USA), vol.88, no.C5, p.2723-32 (30 March 1983). [received: Sept. 1983]
Presents long-term ($\sim$230-day) measurements from three moorings in the vicinity of Saint Lawrence Island on the northern Bering Sea shelf. One mooring was deployed near the polynya which often exists south of the island. These data confirm the existence of strong ($\sim$0.15 m s^{-1}) flow toward Bering Strait northwest of the island (in Anadyr Strait) and suggest that regional circulation results in a moderate ($\sim$0.035 m s^{-1}) mean flow eastward along the southern coast of Saint Lawrence Island. Coherent variations in the regional circulation and variations in the geostrophic wind account for much of the low-frequency current fluctuation south of Saint Lawrence Island. However, there were 11 events when offshore (northerly) winds coincided with the temperature following the freezing point, increasing salinity, and reversal of the current. This suggests that ice formation and the ensuing brine rejection affect flow in the vicinity of the polynya. (25 refs.)

110405 Multiyear sea ice variability in the eastern Bering Sea: an update. H.J.Niebauer (Inst. of Marine Sci., Univ. of Alaska, Fairbanks, AL, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2733-42 (30 March 1983). [received: Sept. 1983]
Time series of sea surface temperature (SST), percent ice cover degree day, and surface wind anomalies are updated from Niebauer [1980] for the period 1974-1982 from the eastern Bering Sea. These data are used to provide further documentation of the recent short-term ($\sim$1977-present) climatic warming trend in the region of the eastern Bering Sea. The data analysis indicates that the warming trend is statistically significant and that it ended in 1979. Details of the anomalies in SST, ice and surface, and 700-mbar winds are updated for the individual winters of 1979-82, are compared and contrasted to the recent multilayer warming trend and are discussed in relation to longer-term studies of air-ice-sea interactions in this region. (23 refs.)

110406 Nimbus 7 SMMR observations of the Bering Sea ice cover during March 1979. D.J.Cavalieri (Goddard Lab. for Atmospheric Sci., NASA Goddard Space Flight Center, Greenbelt, MD, USA), S.Martin, P.Gloersen.
J. Geophys. Res. (USA), vol.88, no.C5, p.2743-54 (30 March 1983). [received: Sept. 1983]
A method of deriving sea ice concentrations from the 0.81-cm wavelength radiances of the Nimbus 7 scanning multichannel microwave radiometer (SMMR) is described and used in a comparative study of the Bering Sea ice cover during March 1979. Case studies during 2 days in March demonstrate the utility of the SMMR for studying marginal ice zone processes. The first day provides an example of ice divergent conditions with winds from the northeast advecting the ice southwest toward the ice edge. Comparison of the SMMR-derived ice concentration maps with surface, aircraft, and Tiros-derived ice charts shows that the microwave data give the ice edge position to within 30 km, corresponding to the highest spatial resolution of SMMR. (17 refs.)

110407 Oceanographic conditions in the marginal ice zone north of Svalbard in early fall 1979 with an emphasis on mesoscale processes. O.M.Johannessen, J.A.Johannessen (Geophys. Inst., Univ. of Bergen, Bergen, Norway), J.Morison, B.A.Farrelly, E.A.S.Svendsen.
J. Geophys. Res. (USA), vol.88, no.C5, p.2755-69 (30 March 1983). [received: Sept. 1983]
During September-October 1979 the Norwegian Remote Sensing Experiment was carried out in the marginal ice zone north of Svalbard. Convergence of the ice cover is correlated with along-ice edge winds with the ice to the right, while divergence occurs during off-ice winds or calm conditions. A wind-driven ice edge jet, is observed. Wind-driven upwelling of the pycnocline of up to 7 m was present along the ice edge during a 10- to 15-m/s easterly wind event. The upwelling is due to Ekman divergence at the ice edge, caused by higher wind stress over ice than over open water. The ice edge meanders with a scale of 20-40 km and sheds eddies with a scale of 5 to 15 km into the open water. (43 refs.)

110408 An ice-water vortex at the edge of the East Greenland current. P.Wadhams, V.A.Squire (Scott Polar Res. Inst., Univ. of Cambridge, Cambridge, England).
J. Geophys. Res. (USA), vol.88, no.C5, p.2770-80 (30 March 1983). [received: Sept. 1983]
During the Ymer-80 cruise in August 1980 an ice feature of 60-km diameter was observed having the shape of a breaking wave. It lay at the edge of the East Greenland drift ice in Fram Strait with its center at 79°15′N, 00°38′E, and the wave was breaking upstream relative to the East Greenland Current. Two conductivity, temperature, and depth sections across the feature in N-S and E-W directions revealed warm (up to 4.3°C) water some 60 km inside the polar front, in lenses centered at 40-m depth but with an effect to beyond 600 m. The temperature anomalies were accompanied by salinity anomalies so that there was little net effect on the density profile. The form of the sections, together with the ice distribution (observed by vertical photography from a helicopter) and surface motion (observed by tracking four radar transponders) all suggest that the feature is a vortex produced by an instability in the polar front. (12 refs.)

110409 Norwegian remote sensing experiment: evaluation of the Nimbus 7 scanning multichannel microwave radiometer for Sea Ice research. E.Svendsen (Geophys. Inst., Univ. of Bergen, Bergen, Norway), K.Kloster, B.Farrelly, O.M.Johannessen, J.A.Johannessen, W.J.Campbell, P.Gloersen, D.Cavalieri, C.Matzler.
J. Geophys. Res. (USA), vol.88, no.C5, p.2781-91 (30 March 1983). [received: Sept. 1983]
An algorithm has been developed for estimating total and multilayer sea ice concentration from passive microwave and surface air temperature measurements. The algorithm was made for use with Nimbus 7 scanning multichannel microwave radiometer (SMMR) data. It is based on radiation physics and may thus easily be modified to suit other passive microwave instruments. A comparison between Nimbus 7 SMMR and aircraft microwave measurements indicates that estimates of total ice concentration are accurate to ±3% and those of multilayer ice concentration to ±10%. These accuracies are not valid during the melt season when the snow on the ice is wet. (12 refs.)

110410 On the seasonal sea ice cover of the Sea of Okhotsk. C.L.Parkinson (Goddard Lab. for Atmospheric Sci., NASA/Goddard Space Flight Center, Greenbelt, MD, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2793-802 (30 March 1983). [received: Sept. 1983]
Free of ice 4 months of the year, the Sea of Okhotsk begins to freeze over in a few coastal locations in November, attains its maximum ice coverage usually in mid March, and by June retains ice in only a few coastal regions. This sequence is well recorded by satellite imagery from the Electrically Scanning Microwave Radiometer (ESMR) on board Nimbus 5. Four years of ESMR data reveal significant interannual variations in the maximum ice cover and in the smoothness of the growth and retreat periods. The years 1973-1976 were studied. The general features of the cycle of sea ice distribution are compared with basic oceanographic factors. (21 refs.)

110411 The movement and decay of ice edge bands in the winter Bering Sea. S.Martin, P.Kauffman (School of Oceanography, Univ. of Washington, Seattle, WA, USA), C.Parkinson.
J. Geophys. Res. (USA), vol.88, no.C5, p.2803-12 (30 March 1983). [received: Sept. 1983]
During periods of off-ice winds, the winter Bering Sea ice edge consists of ice bands that measure 1-10 km in length, 0.1-1 km in width, and are oriented at approximately right angles to the wind. The bands are composed of small floes 10-20 m in diameter and 1-5 m in thickness. In March 1981 working from the NOAA ship Surveyor, the authors mounted two radar transponders 4 km apart on ice floes within such a band and then tracked them for 46 h over an 80 km distance as the band moved into warmer water and melted. Comparison of the band position with that of a satellite-tracked ARGOS station deployed in the ice interior shows that the band moved 30% faster than the interior ice. Analysis of the observations strongly suggest that the cause of the speed increase is the wind-wave radiation stress on the upwind side of the band. (9 refs.)

110412 A mechanism for the formation of ice edge bands. P.Wadhams (Scott Polar Res. Inst., Univ. of Cambridge, Cambridge, England).
J. Geophys. Res. (USA), vol.88, no.C5, p.2813-18 (30 March 1983). [received: Sept. 1983]
A mechanism is proposed for the formation of multiple bands at an ice edge that is subjected to an off-ice wind. The wind moves the outermost floes seaward faster than the interior ice, dilating the marginal ice zone and opening up random polynyas. In the largest of the polynyas, the off-ice wind generates a significant fetch-limited wave spectrum, which produces a wave radiation pressure on floes at the downwind end of the polynya, increasing their velocity. They are herded against their downwind neighbors, creating a band of high ice concentration. The band is stabilized by an internal compacting stress due to the exponential decay of the wind-wave spectrum across the band and to a slower decay of swell incident from seaward. The band's growth terminates when it encounters a second downwind polynya of sufficiently large size. (23 refs.)

110413 On some possible interactions between internal waves and sea ice in the marginal ice zone. R.D.Muench (Sci. Applications Inc., Bellevue, WA, USA), P.H.LeBlond, L.E.Hachmeister.
J. Geophys. Res. (USA), vol.88, no.C5, p.2819-26 (30 March 1983). [received: Sept. 1983]
The ice edges of the world ocean are generally the site, at times when winds are blowing off the ice, of regularly spaced surface bands of ice floes. These bands have size scales of the order of 1-10 km, and their long axes are oriented approximately normal to the wind direction. Available oceanic temperature and salinity data from the Bering and Greenland Sea ice edge regions suggest that these ice bands are commonly underlain by a two-layered density structure which is maintained by net melting along the ice edges.

Linear internal wave theory is applied to these data to compute first-mode interfacial wave phase speeds. A simple analytical model is developed that demonstrates the feasibility of generation of such interfacial internal waves by the stress discontinuity due to off-ice winds blowing over either a stationary or a moving ice edge. Ice band phenomena are discussed. (20 refs.)

110414 Turbulent heat and momentum transfer in the oceanic boundary layer under melting pack ice. M.G.McPhee (Naval Postgraduate School, Monterey, CA, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2827-35 (30 March 1983). [received: Sept. 1983]
A theory for momentum flux in the planetary boundary layer (PBL) stabilized by continuous surface buoyancy is extended to include turbulent flux of an arbitrary scalar contaminant and then used to estimate how wind-driven sea ice melts as it encounters temperatures in the oceanic boundary layer that are above the melting point. Given wind stress and temperature difference $\Delta\theta$ across the oceanic PBL, the theory predicts melt rate and ice drift velocity. Results indicate that the effect of buoyancy on PBL turbulence is significant even with small values of $\Delta\theta$ (<0.5K). Curves of melt rate and ice speed as functions of u_*, the interfacial friction velocity, show that melting is strongly dependent on stress at the interface and that the effective drag on the ice undersurface is significantly reduced at oceanic temperatures commonly observed in the marginal ice zone. (14 refs.)

110415 Sea ice melting in the marginal ice zone. E.G.Josberger (US Geological Survey, Univ. of Puget Sound, Tacoma, WA, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2841-4 (30 March 1983). [received: Sept. 1983]
The heat and salt flux boundary conditions together with the freezing curve relationship are a necessary component of any ice-sea water thermodynamic model. A neutral two-layer oceanic planetary boundary layer model that incorporates these boundary conditions gives the following results: the interfacial salinity is within 10% of the far-field salinity for conditions commonly encountered in the MIZ and depends only on the turbulent Lewis number and the far-field temperature and salinity. The predicted melt rates agree with the limited field observations, of the order of 1 m day^{-1}. The Obukov lengths, determined from the predicted interface conditions and melt rates, are generally much greater than the Ekman layer thicknesses; hence, the surface buoyancy flux has little effect on the turbulence in the planetary boundary layer. (11 refs.)

110416 Wind drag coefficient over first-year sea ice in the Bering Sea. S.A.Macklin (Pacific Marine Environmental Lab./NOAA, Seattle, WA, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2845-52 (30 March 1983). [received: Sept. 1983]
Profiles of relative wind speed and temperature were collected from four levels over rough sea ice in the marginal ice zone of the Bering Sea and used to compute surface wind drag coefficients. Based upon 138 profiles for near-constant ice conditions, northeast winds of 3-15 m s^{-1}, and near-neutral stability, the mean, near-neutral, 10-m drag coefficient was 0.00309 ± 0.00049. This is among the largest drag coefficients measured for neutral atmopheric conditions over sea ice. Sixty-five percent of the variance of this estimate is explained by orientation of the ice floe to the wind; an additional 5% of the variance is explained by wind-speed dependence. (21 refs.)

110417 Drag measurements for first-year sea ice over a shallow sea. C.H.Pease, S.A.Salo, J.E.Overland (Pacific Marine Environmental Lab., NOAA, Seattle, WA, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2853-62 (30 March 1983). [received: Sept. 1983]
For a free-drift case a method is developed for simultaneously determining air (C_a) and water (C_w) drag coefficients by solving the vertically integrated stress balance equation for sea ice. The method allows the algebraic determination of C_a and C_w from measurements of relative wind and relative current at single reference levels, from estimates of the densities of all three fluids and ice thickness, and from estimates of the accelerations caused by the nonsurface stress terms derived from position measurements. The method treats the ice as a natural drag plate and therefore includes contributions from both skin and form drag. An experiment was conducted on a single floe in the eastern Bering Sea over the continental shelf during March 1981. The site was about 80 km from the ice edge and was occupied for approximately 3 days following the passage of a storm which had broken the pack into 10-20 m diameter floes. Both profile and slab inversion estimates of drag were made. (23 refs.)

110418 A coupled ice-ocean model of upwelling in the marginal ice zone. L.P.Roed (Inst. of Geophys., Univ. of Oslo, Oslo, Norway), J.J.O'Brien.
J. Geophys. Res. (USA), vol.88, no.C5, p.2863-72 (30 March 1983). [received: Sept. 1983]
A dynamical coupled ice-ocean numerical model for the marginal ice zone (MIZ) is suggested and used to study upwelling dynamics in the MIZ. The nonlinear sea ice model has a variable ice concentration and includes internal ice stress. The model is forced by stresses on the air/ocean and air/ice surfaces. The main coupling between the ice and the ocean is in the form of an interfacial stress on the ice/ocean interface. The ocean model is a linear reduced gravity model. The wind stress exerted by the atmosphere on the ocean is proportional to the fraction of open water, while the interfacial stress ice/ocean is proportional to the concentration of ice. A new mechanism for ice edge upwelling is suggested based on a geostrophic equilibrium for the sea ice medium. (33 refs.)

110419 Numerical simulation of the Weddell Sea pack ice. W.D.Hibler,III, S.F.Ackley (US Army Cold Regions Res. & Engng. Lab., Hanover, NH, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2873-87 (30 March 1983). [received: Sept. 1983]
To investigate the role of ice dynamics on the seasonal cycle of Antarctic sea ice, a series of 2-year simulations of the Weddell sea pack ice are carried out. The simulations employ the dynamic thermodynamic model developed by Hibler (1979) and use 1-day time step on an 18×15 grid with a resolution of 222 km. Daily atmospheric data from 1979 are used to drive the simulations. With atmospheric temperature fields modified to reflect buoy observations, the simulations yield a seasonal cycle of ice with maximum and minimum extents close to that observed. Except for portions of the western Weddell, the advance of the ice is found to be primarily thermodynamic in nature, while the rapid decay depends critically on the presence of both leads and lateral ice advection. The average fraction of open water is substantial even in winter, and varies from a minimum of 10% in September to a maximum of 35% in March. (29 refs.)

110420 An investigation of a polynya in the Canadian Archipelago. I. Introduction and oceanography. D.R.Topham, R.G.Perkin (Inst. of Ocean Sci., Sidney, British Columbia, Canada), S.D.Smith, R.J.Anderson, G.Den Hartog.
J. Geophys. Res. (USA), vol.88, no.C5, p.2888-99 (30 March 1983). [received: Sept. 1983]
In certain parts of the Canadian Archipelago, small localized areas of water remain ice free throughout the winter, despite the extreme temperature differences between the atmosphere and the ocean surface. One such area, close to the Dundas Island, has been studied in detail, both from the point of view of the atmospheric/oceanic heat exchange over the open water and its local geographic and oceanographic context. This paper describes the oceanography of the area and local weather and tidal flow conditions. A significant feature of the oceanographic records is a strong modulation of near-surface ocean temperature at tidal frequencies involving temperature differences as great as 0.2°C within a single tidal cycle. For the most part, the surface waters are 0.1° to 0.2°C above freezing. The presence of this relatively warm surface water is thought to be due to upward mixing occasioned by fast tidal flows across the shallow sill conncting Dundas and Devon islands. (20 refs.)

110421 An investigation of a polynya in the Canadian Archipelago. II. Structure of turbulence and sensible heat flux. S.D.Smith, R.J.Anderson (Bedford Inst. of Oceanography, Dartmouth, Nova Scotia, Canada), G.Den Hartog, D.R.Topham, R.G.Perkin.
J. Geophys. Res. (USA), vol.88, no.C5, p.2900-10 (30 March 1983). [received: Sept. 1983]
For pt.I see ibid., vol.88, no.C5, p.2888-99 (1983). The Dundas Island polynya is a natural laboratory for the study of atmospheric turbulence and heat exchange between the Arctic Ocean and the atmosphere in extreme (20-34°C) sea-air temperature differences. Wind and temperature fluctuations were measured at a height of 4.4 m at the downwind edge, where turbulent heat flux was characteristic of the surface flux from the polynya. Profiles of wind, temperature, and temperature fluctuations were also measured. Temperature ramps associated with the passage of convective plumes give skewed temperature distributions. Formulas described turbulence structure in convective boundary layers in terms of 'similarity' theory are verified and compared with published results taken in less extreme temperature gradients. Heat flux can be estimated from either temperature variance or temperature spectra. (38 refs.)

110422 An investigation of a polynya in the Canadian Archipelago. III. Surface heat flux. G.Den Hartog (Atmospheric Environment Service, Downsview, Ontario, Canada), S.D.Smith, R.J.Anderson, D.R.Topham, R.G.Perkin.
J. Geophys. Res. (USA), vol.88, no.C5, p.2911-16 (30 March 1983). [received: Sept. 1983]
For pt.II see ibid. vol.88, no.C5, p.2900-10 (1983). The heat loss from the Dundas Island polynya is calculated for a 3 week period during March 1980. Bulk and free convection formulae based on sonic anemometer-thermometer measurements are used to calculate sensible and latent heat fluxes. These terms, along with simple models to calculate the albedo and the long-wave radiation exchanges, yield a surface heat budget for the polynya. The sensible heat flux for the period March 12, 1980, to April 1, 1980, averaged 204 W/m^2 and the mean total heat loss from the polynya was 329 W/m^2. (16 refs.)

110423 A model of grease ice growth in small leads. J.Bauer, S.Martin (School of Oceanography, Univ. of Washington, Seattle, WA, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2917-25 (30 March 1983). [received: Sept. 1983]
When a strong, cold wind blows over open polar leads, ice grows in the form of small crystals which are herded downwind by both wind waves and a wind-driven surface current to pile up at the downwind edge of the lead. As this process continues, the piled-up ice, called 'grease ice', advances upwind until the entire lead is ice covered. In a numerical model of ice growth in a horizontally one-dimensional lead with a wind blowing along its length, the wave field and surface current, which are functions of wind speed and fetch, are used to calculate the ice pileup depth and the ice cover advance rate. (38 refs.)

110424 Initial model results for Arctic mixed layer circulation under a refreezing lead. T.L.Kozo (Polar Sci. Center, Univ. of Washington, Seattle, WA, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2926-34 (30 March 1983). [received: Sept. 1983]
At the temperatures in the Arctic Ocean mixed layer during lead-induced surface water cooling, convection is primarily salinity controlled owing to continuous brine expulsion from newly forming ice. A nonlinear, time-dependent, convective model has been developed that simulates existing field data obtained on the circulation characteristics under and near a refreezing lead. The model uses typical Arctic Ocean ambient conditions as initial input and allows for imposition of varying geostrophic currents. The zero geostrophic current (free convective case) model output for typical lead surface salt input resulted in maximum horizontal current velocities of 0.05 m s^{-1} eddy viscosities on the order of 0.01 $m^2\ s^{-1}$, average salt fluxed beneath the lead of 3.3×10^{-5} kg $m^{-2}\ s^{-1}$, and a subsequent increase in the depth of the mixed layer. (29 refs.)

110425 Melting characteristics of horizontal ice surfaces in cold saline water. B.Gebhart, B.Sammakia (Dept. of Mech. Engng. & Appl. Mech., Univ. of Pennsylvania, Philadelphia, PA, USA), T.Audunson.
J. Geophys. Res. (USA), vol.88, no.C5, p.2935-42 (30 March 1983). [received: Sept. 1983]
The results of a laboratory experimental investigation of the buoyancy driven flow adjacent to and below a horizontal ice surface melting in cold water at near oceanic salinity are presented. This melting configuration is characteristic of circumstances encountered by sea ice. Several ambient water temperatures t_∞ are investigated, from $t_\infty = -1.75$°C to $t_\infty = 3$°C. Time exposure photographs of the flow field reveal that distinctively different flow regimes occur, across even that narrow range of ambient temperature. At all temperature levels, the flow immediately below the sea surface is found to be horizontally radially inward toward the center of the ice. Also, another outward moving horizontal layer appeared, parallel to and below the inward moving layer. The downward extent of penetration of this layer motion was studied. (19 refs.)

110426 Measurements of salinity and volume and brine excluded from growing sea ice. M.Wakatsuchi, N.Ono (Inst. of Low Temperatures Sci., Hokkaido Univ., Sapporo, Japan).
J. Geophys. Res. (USA), vol.88, no.C5, p.2943-81 (30 March 1983). [received: Sept. 1983]
The volume of brine excluded from growing sea ice and its salinity were measured using a brine sampler. The measurements were made, on both laboratory and field, under various growth conditions of the sea ice. The salinity of the brine becomes higher, and the volume flux decreases as the sea ice growth rate decreases. Consequently, the salt flux of the brine decreases

with decreasing growth rate. In the case of sea ice growth at a constant rate, as the sea ice becomes thicker, the salinity of the brine excluded increases while its volume flux decreases. However, the salt flux is nearly independent of the ice thickness increase, at least up to a thickness of 15 cm. (11 refs.)

110427 Numerical study of the water movement driven by brine rejection from nearshore arctic ice. Z.Kowalik, J.B.Matthews (Geophys. Inst., Univ. of Alaska, Fairbanks, AL, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2953-8 (30 March 1983). [received: Sept. 1983]
A numerical model of brine-induced circulation is used to study circulation in the lagoons and shelf waters of the Beaufort Sea. The model solves the equations of motion, continuity, and salt transport. The salt flux is set as a function of the salinity difference between growing sea ice and seawater and the rate of ice growth. Several experimental runs show that under-ice haline circulation is controlled by salt flux and bottom configuration. An idealized model of a shallow arctic lagoon gives currents of 1 cm s^{-1} for brine-induced circulation under landfast ice. This agrees very well with observations. (21 refs.)

110428 New measurements of sulfate and chlorinity in natural sea ice. W.S.Reeburgh, M.Springer-Young (Inst. of Marine Sci., Univ. of Alaska, Fairbanks, AL, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2959-66 (30 March 1983). [received: Sept. 1983]
Precise determinations of sulfate and chlorinity were made on SIPRE core samples of natural sea ice. One ice was a multiyear ice that had remained attached to T-3 (Fletcher's Ice Island) for over 20 years and the other was a shore-fast annual ice collected near Barrow, Alaska. The results show sulfate: chlorinity ratios different from the seawater ratio. A mixing model shows that on warming and aging, sulfate and chlorinity are lost in a constant ratio, indicating conservative behavior. Fractionation in sea ice appears to be determined in the freezing process and further enrichment does not take place with aging. The effects of sulfate fractionation in sea ice are too small and the residence times of both sea ice and Arctic Ocean surface water are too short to permit detectable modification of seawater composition by freezing. (53 refs.)

110429 Edge waves as a cause of ice rideup onshore. E.Mollo-Christensen (Dept. of Meteorology & Phys. Oceanography, MIT, Cambridge, MA, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2967-70 (30 March 1983). [received: Sept. 1983]
Edge waves on ice-covered water, generated elsewhere by wind, current, or wave impingement at the ice edge, can reach large amplitudes where bottom slope and current combine to give low group velocity. The amplitude of water velocity normal to shore can become large, and the resulting acceleration of the ice cover onto shore may be sufficient to cause ice rideup. Edge waves on an ice-covered ocean with a mean current are analyzed to a linear approximation, and estimates are given of velocities and amplitudes. (6 refs.)

110430 Interactions between waves and mean drift in an ice pack. E.Mollo-Christensen (Dept. of Meteorology & Phys. Oceanography, MIT, Cambridge, MA, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2971-2 (30 March 1983). [received: Sept. 1983]
In a drifting ice pack, the mean drag depends upon the amplitude of oscillations present, and it reaches a maximum when the amplitude of oscillations along the direction of mean drift equals the drift velocity. The damping of waves entering a pack increases with increasing drift velocity, so waves entering a drifting pack will vary in amplitude because of dissipation. The dispersion of surface gravity waves in an ice pack under compression shows that the group velocity of the waves decreases with increasing mean compressive stress, so there can also be dispersive mechanisms causing wave amplitude variations within the ice peak. The observations in the Norwegian Remote Sensing Experiment, namely that the drag in a drifting pack varied with distance from the pack edge, are in general concord with these results. (4 refs.)

110431 Azimuthal structure of a cyclonic Gulf Stream ring. R.P.Mied, G.J.Lindemann (Environmental Sci. Div., Naval Res. Lab., Washington, DC, USA), J.M.Bergin.
J. Geophys. Res. (USA), vol.88, no.C4, p.2530-46 (20 March 1983). [received: Sept. 1983]
During the period June 8-19, 1979, an intensive expendable bathythermograph survey of a Gulf Stream ring was made. After mapping the irregularly spaced data onto a regular grid, and azimuthally decomposing the temperature field at constant depth into Fourier constituents $e^{in\theta}$, the $n=2$ model was found to be the dominant one. The geostrophic stream function was calculated utilizing the hydrostatic equation and the measured temperature/salinity curves. (19 refs.)

110432 The temperature and salinity finestructure of the ocean under the Ross Ice Shelf. T.D.Foster (Univ. of California, Santa Cruz, CA, USA).
J. Geophys. Res. (USA), vol.88, no.C4, p.2556-64 (20 March 1983). [received: Sept. 1983]
A series of temperature and salinity profiles was made in the ocean under the Ross Ice Shelf at 82°22.5′S, 168°37.5′W where the ice was 420 and the underlying seawater 240 m thick. The water structure consisted of a fairly well-mixed, low salinity layer at the in situ freezing point of the ice-water interface about 30 m thick, a transition layer characterized by intrusions about 85 m thick, a strongly stratified layer with increasing temperature and salinity about 50 m thick, another transition layer characterized by intrusions about 45 m thick, and an isohaline bottom layer with a nearly abiabatic temperature gradient about 30 m thick. The temperature fluctuations in the two transition layers can be attributed mainly to intrusive activity even though internal wave activity was highest in these regions. (30 refs.)

110433 Phytoplankton and thermal structure in the upper ocean: consequences of nonuniformity in chlorophyll profile. M.R.Lewis, J.J.Cullen, T.Platt (Marine Ecology Lab., Bedford Inst. of Oceanography, Dartmouth, Nova Scotia, Canada).
J. Geophys. Res. (USA), vol.88, no.C4, p.2565-70 (20 March 1983). [received: Sept. 1983]
Nonuniformities in vertical chlorophyll (phytoplankton) distributions lead to nonuniformities in absorption and consequently to variations in local heating. Local heating rate tends to decrease monotonically with increasing depth, but certain vertical distributions of chlorophyll lead to a change of sign of the gradient. Data from an oligotrophic ocean station showed a subsurface maximum of chlorophyll intense enough to allow increased heating on the upper slope of the chlorophyll maximum, with a maximum gradient of 0.003°C d^{-1} m^{-1}. It is suggested that the importance of such subsurface heating for augmenting vertical mixing and influencing mixed layer deepening may be greatest in the optically clear, open ocean regions. (47 refs.)

110434 Island shadows in wave directional spectra. S.S.Pawka (Shore Processes Lab., Scripps Inst. of Oceanography, La Jolla, CA, USA).
J. Geophys. Res. (USA), vol.88, no.C4, p.2579-91 (20 March 1983). [received: Sept. 1983]
Shadows of individual islands are observed in directional spectra sampled with a high resolution linear array at Torrey Pines Beach, California. A detailed investigation of the spectra indicates that the Channel Islands restrict the wave energy density to certain narrow directional sensors. A deep spectral trough, associated with San Clemente Island, is a predominant feature in the well resolved spectra (wave frequencies ~0.06-0.15 Hz). Negligible values of energy density in the center of this directional 'gap' were consistently observed in the range 0.82-0.114 Hz. Measurable but low gap energy density values are seen in the high and low frequency regimes. Generation of high frequency waves ($f \geq 0.13$ Hz) by local winds generally smears the island windowing effects. (16 refs.)

110435 Bottom-water observations in the Vema fracture zone. S.L.Eittreim (US Geological Survey, Menlo Park, CA, USA).
J. Geophys. Res. (USA), vol.88, no.C4, p.2609-14 (20 March 1983). [received: Sept. 1983]
The Vema fracture zone trough, at 11°N between 41° and 45° W is open to the west at the 5000-m level but is silled at the 4650-m level on the east where it intersects the axis of the Mid-Atlantic Ridge. The trough is filled with Antarctic Bottom Water with a potential temperature of 1.32°C and salinity of 34.82 ppt. The bottom water is thermally well mixed in a nearly homogeneous layer about 700 m thick. The great thickness of this bottom layer may result from enhanced mixing induced by topographic construction at the west end of the fracture zone trough. The authors also studied the benthic thermocline, the currents and the turbidity of the deep ocean. (19 refs.)

110436 Coastal sea level response to frontal passages on the Louisiana-Texas shelf. Wen-Ssn Chuang, W.J.Wiseman,Jr. (Coastal Studies Inst., Louisiana State Univ., Baton Rouge, LA, USA).
J. Geophys. Res. (USA), vol.88, no.C4, p.2615-20 (20 March 1983). [received: Sept. 1983]
Sea level variations resulting from wind forcing along the Louisiana-Texas shelf are examined on 5-month winter records. Local weather patterns during the winter are dominated by cold-front passages. The associated surface wind field is well organized, predominantly in the cross-shell direction. Regional sea level response, however, shows considerable variability; it is mainly a response to alongshore wind at Galveston, but cross-shelf wind at Eugene Island. This spatially nonuniform response appears to be due to the different water depth over the inner shelf, which is shallower off Eugen Island and favors direct cross-shelf wind setup. A friction model is applied to each region. (24 refs.)

110437 SEASAT-derived ocean surface topography: comparison with coincident Kuroshio hydrographic data. H.M.Byrne, P.E.Pullen (NOAA, Pacific Marine Environmental Lab., Seattle, WA, USA).
J. Geophys. Res. (USA), vol.88, no.C4, p.2621-5 (20 March 1983). [received: Sept. 1983]
During the SEASAT repeat-orbit period, a CTD and deep XBT hydrographic experiment was conducted across the Kuroshio to obtain contemporaneous surface topography measurements for comparison with the altimeter-derived surface height measurements. The results showed that the altimeter could detect and measure the change in sea surface topography caused by movement of the Kuroshio and the cold rings that were found in the hydrographic data. The altimeter measured changes in the surface topography that matched those measured by the hydrographic sections. (12 refs.)

110438 Mean heat and momentum budgets during upwelling for the coastal waters off northwest Africa. J.Richman, A.Badan-Dangon (School of Oceanography, Oregon State Univ., Corvallis, OR, USA).
J. Geophys. Res. (USA), vol.88, no.C4, p.2626-32 (20 March 1983). [received: Sept. 1983]
Mean heat and momentum budgets for the upwelling region off northwest Africa during March and April 1974 are estimated at midshelf, 32 km from the coast, using current and temperature measurements at six depths in 73 m of water. In the heat budget, the mean cross-shelf circulation transports 1.14×10^{7} W m^{-1} offshore, while fluctuations in the cross-shelf circulation transport an additional 1.9×10^{6} W m^{-1} offshore. This offshore heat flux is compensated by the net radiative heat gain in the region and an alongshore heat flux due to the mean circulation. In the cross-shelf momentum budget, the alongshore flow is nearly geostrophic with the Coriolis force being approximately balanced by the steric sea level slope. For the alongshore momentum budget, the surface wind stress is balanced by the bottom stress, alongshore pressure gradient, and Coriolis force associated with the net onshore mass transport. (25 refs.)

110439 Some estimates of transport processes in Long Island Sound. D.Tolmazin (Dept. of Marine Sci., Univ. of Connecticut, Groton, CT, USA).
J. Geophys. Res. (USA), vol.88, no.C4, p.2633-41 (20 March 1983). [received: Sept. 1983]
A parametric description of lateral and vertical oscillatory transport in two segments of Long Island Sound is presented. The vertical eddy viscosity and diffusivity coefficients are estimated on the basis of a model for turbulent kinetic energy transfer. Characteristics of horizontal mixing are examined by means of dimensional analysis. The relative importance of the mechanisms controlling mass distribution in the estuary is evaluated by calculating longitudinal dispersion coefficients in a form introduced by Fisher (1972). It is shown that the mass transport in Long Island Sound is governed mainly by two processes: lateral turbulent disperion and net longitudinal transport caused by the density gradients. (42 refs.)

110440 Tidal phase of internal-wave generation. C.Sawyer (NOAA, ERL, Pacific Marine Environmental Lab., Seattle, WA, USA).
J. Geophys. Res. (USA), vol.88, no.C4, p.2642-8 (20 March 1983). [received: Sept. 1983]
The tidal phase at which ocean internal waves are generated is examined by using two sets of data. The first data set, consisting of 21 time series of internal-wave packets located with respect to the continental shelf edge on satellite images, clearly indicates generation near flood tide. In the second data set, observations of thermal oscillations shoreward of a sill can be modeled either as generated shortly after ebb tide on the seaward side of the sill or slightly before flood on the shoreward side. The absence in both sets of observations of evidence of internal waves over the sill or seaward of the sill points to flood generation at the sill as well as at the shelf. The shelf edge is found to be the most likely site of tidal generation of internal waves observed over the shelf. (15 refs.)

110441 Generation of internal waves in Massachusetts Bay. T.K.Chereskin (Dept. of Meteorology & Phys. Oceanography, MIT, Cambridge, MA, USA).

J. Geophys. Res. (USA), vol.88, no.C4, p.2649-61 (20 March 1983). [received: Sept. 1983]

Observations of stratified tidal flow over a submarine ridge indicate that the large amplitude and asymmetry of the topography are critical in determining the type of flow response. The observations consist of hydrographic, current meter, and echo-sounding data and are used as a basis for inferring the generation mechanism of previously observed trains of internal waves. The flow response on ebb and flood tide is categorized according to the Froude number classification of sill flows proposed by Farmer and Smith (1980*a*). The calculated Froude numbers, response length scale, and duration differ markedly between the two phases of the tide due to the symmetry of the bank. (12 refs.)

110442 On the stratification of turbulent mixed layers. L.Mahrt, J.-C.Andre (Atmospheric Sci. Dept., Oregon State Univ., Corvallis, OR, USA).

J. Geophys. Res. (USA), vol.88, no.C4, p.2662-6 (20 March 1983). [received: Sept. 1983]

The vertical distribution of density or temperature is studied in turbulent boundary layers stratified by either salt or temperature and driven in an annulus by a rotating screen. With rapidly growing boundary layers the buoyancy flux due to entrainment becomes sufficiently large that the boundary layer is no longer well mixed. Stratification in the boundary layer is largest near the entrainment interface, corresponding to extension of the density transition into the turbulent boundary layer. The stratification in the rest of the boundary layer is smaller and nearly independent of height. The mean boundary layer stratification and structure and integral properties of the density distribution are found to be strongly dependent on the ratio of the entrainment rate to the turbulent velocity scale. (15 refs.)

110443 Geochemical profiles in the central Arctic Ocean: their relation to freezing and shallow circulation. R.M.Moore, M.G.Lowings (Dept. of Oceanography, Dalhousie Univ., Halifax, Nova Scotia, Canada), F.C.Tan.

J. Geophys. Res. (USA), vol.88, no.C4, p.2667-74 (20 March 1983). [received: Sept. 1983]

Temperature, salinity, nutrient, tritium, and oxygen isotope data collected during the Lomonosov Ridge Experiment along a drift track between the Makarov and Fram Basins over the Lomonosov Ridge are presented. The relationship of these quantities to the processes that maintain the halocline, in particular to the production of more saline waters by addition of brines formed during the freezing of seawater, is described. The results support the idea that the wide continental shelves of the Arctic Ocean play an important role in maintaining the halocline. (17 refs.)

110444 A vertical section of eddy kinetic energy through the Gulf Stream system. P.L.Richardson (Woods Hole Oceanographic Instn., Woods Hole, MA, USA).

J. Geophys. Res. (USA), vol.88, no.C4, p.2705-9 (20 March 1983). [received: Sept. 1983]

Ocean current observations made by drifting buoys, SOFAR floats, and current meters are combined to produce the first section of eddy kinetic energy through the Gulf Stream and subtropical gyre along 55°W. Eddy kinetic energy peaks at 2000 $cm^2 s^{-2}$ in the surface Gulf Stream near 39°N and decreases latitudinally and vertically to a low of 0.5 $cm^2 s^{-2}$ in the abyssal gyre interior (4000 m, 28°N). Still further south, eddy energy increases slightly in the region of the North Equatorial Current. (20 refs.)

110445 Wave evolution over a gradual slope with turbulent friction. J.W.Miles (Inst. of Geophys. & Planetary Phys., Univ. of California, La Jolla, CA, USA).

J. Fluid Mech. (GB), vol.133, p.207-16 (Aug. 1983).

The evolution of a weakly nonlinear, weakly dispersive gravity wave in water of depth d over a bottom of gradual slope δ and Chezy friction coefficient C_f is studied. It is found that an initially sinusoidal wave evolves into a periodic sequence of solitary waves with relative amplitude $a/d=\alpha_1=15\delta/4C_f$ if $\alpha_1<\alpha_b$, where α_b is the relative amplitude above which breaking occurs. This prediction is supported by observations (Wells 1978) of the evolution of swell over mudflats. (16 refs.)

110446 Effects of rotation and shear on doubly diffusive instability. S.Worthem (Sea-Air Interaction Lab., NOAA, Miami, FL, USA), E.Mollo-Christensen, F.Ostapoff.

J. Fluid Mech. (GB), vol.133, p.297-319 (Aug. 1983).

A linear stability of a doubly diffusive system, with rotation and shear, shows that overstable oscillations can occur in stratifications typical of the equatorial ocean, that internal waves encountering an equatorial current can exchange energy with the current, and that the wave-induced fluxes of salt and heat can lead to a layer formation in the salinity, temperature and velocity fields. (39 refs.)

110447 A study of the variability of ocean currents in the northwestern Atlantic using satellite altimetry. A.R.Robinson (Centre for Earth & Planetary Phys., Harvard Univ., Cambridge, MA, USA), N.E.Huang, C.D.Leitao, C.G.Parra.

J. Phys. Oceanogr. (USA), vol.13, no.4, p.565-85 (April 1983).

Altimeter data obtained from GEOS-3 during the three-year period 1975-78 for a region of the western North Atlantic which includes a portion of the Gulf Stream system and part of the open ocean area of the subtropical gyre are analysed by a new technique which utilises all the points along the satellite tracks. The physical phenomenon studied are the time-variable but almost geostrophic currents, or mesoscale eddies, so that geoid errors contaminate the scientific signal minimally and the dynamical interpretation is direct. Results presented include the spatial distribution of geostrophic eddy kinetic energy and examples of a synoptic map of the eddy field (April 1977) and of a time series at a point. (48 refs.)

110448 An estimation of sea-level and surface-current anomalies during the 1972 El Nino and consequent thermal effects. A.E.Gill (Dept. of Appl. Math. & Theoretical Phys., Univ. of Cambridge, Cambridge, England).

J. Phys. Oceanogr. (USA), vol.13, no.4, p.586-606 (April 1983).

First, it is shown that if the dynamics is simplified by assuming a one-mode, low-frequency (or long-wave) model, the whole field of anomalous motion in the tropical region can be deduced from the time series of sea-level anomaly at the eastern boundary. This is because the amplitudes of all the equatorial waves are proportional to sea level at this longitude, and the amplitudes at other longitudes can be deduced by integrating along characteristics using the method of Gill and Clarke (1974). The integration proceeds forward in time for the planetary waves and backward in time for the Kelvin wave. The calculation requires a knowledge of wind stress anomalies, although the wind effect only becomes significant after integration to large distances from the eastern boundary. The western boundary is irrelevant to the calculations. The technique is applied to estimate zonal surface current anomalies in the equatorial Pacific for the period 1971-73 spanning a major El Nino. The second part of the paper uses the reconstructed anomaly field of the first part to examine anomalies in the heat balance of the surface layer of the equatorial Pacific. (26 refs.)

110449 Low-frequency current regimes over the Bering Sea shelf. J.D.Schumacher (Environmental Res. Labs., NOAA, Seattle, WA, USA), T.H.Kinder.

J. Phys. Oceanogr. (USA), vol.13, no.4, p.607-23 (April 1983).

Using direct current measurements made during the period 1975-81, the general circulation over the southeastern Bering Sea is described. It is differentiated by regimes related to depth and forcing mechanisms. Three regimes are present, delineated by water depth (z): the coastal ($z\leq50$ m), the middle shelf ($50<z<100$ m), and the outer shelf ($z\geq100$ m). Statistically significant mean flow (~1 to 10 $cm\ s^{-1}$) exists over the outer shelf, generally directed toward the northwest, but with a cross-isobath component. Flow of similar magnitude occurs in the coastal regime, paralleling the 50 m isobath in a counterclockwise sense around the shelf. Mean flow in the middle shelf is insignificant. Kinetic energy at frequencies <0.5 cycle per day is greater over the outer shelf than in the other two regimes, suggesting that oceanic forcing is important there, but does not affect the remainder of the shelf. Kinetic energy in the band from 0.5 to 0.1 cpd follows a similar spatial pattern, reflecting the greater number of storms over the outer shelf. (39 refs.)

110450 The baroclinic stability of the Atlantic North Equatorial Current. T.Keffer (Dept. of Phys. Oceanography, Woods Hole Oceanographic Instn., Woods Hole, MA, USA).

J. Phys. Oceanogr. (USA), vol.13, no.4, p.624-31 (April 1983).

POLYMODE Array III, Cluster C, was a collection of four current meter moorings that were placed in the Atlantic North Equatorial Current for one year in May 1978. They were designed to look for indications of baroclinic instability such as downgradient eddy heat fluxes and upward phase propagation. However, Fu, Keffer and other investigators find that the eddy heat fluxes tended to be more across-gradient and sometimes even upgradient. They also find only slight indications of upward phase propagation. In this study, the linear stability model of Gill et al. is applied to determine the expected heat fluxes, and the modal shapes and scales due to linear amplification. It appears that the expected fluxes should be detectable. Modal shapes are similar to the observed shapes but the fastest growing mode is only about half the size of the observed correlation scale. (17 refs.)

110451 Fine and microstructure observations on a hydrographic section from the Azores to the Flemish Cap. D.T.Georgi (Exxon Production Res. Co., Houston, TX, USA), R.W.Schmitt.

J. Phys. Oceanogr. (USA), vol.13, no.4, p.632-47 (April 1983).

Continuous conductivity-temperature-depth-dissolved-oxygen (CTD) data are used to investigate the spatial distribution of fine and microstructure between the Azores and Flemish Cap. The CTD data are used to calculate a conductivity-microstructure Cox number. This indicator summarises microstructure variance from the 0.08-2 m vertical wavelength range. The CTD data are also used to calculate the finestructure-temperature Cox number. Finally, the fine and microstructure data are combined to calculate lateral flux and flux divergence for the waters east of the North Atlantic Current. The distribution of the conductivity Cox number indicates that vertical mixing is more intense above the base of the main thermocline (5°C isotherm) than below it, and that mixing is more prominent near the North Atlantic Current than farther east. Stations near the front indicate elevated conductivity Cox numbers associated with intrusive features. (34 refs.)

110452 Mid-latitude mesoscale temperature variability in six multiship XBT surveys. D.E.Harrison (Dept. of Meteorology & Phys. Oceanography, Cambridge, MIT, MA, USA), W.J.Emery, J.P.Dugan, Bo-Cheng Li.

J. Phys. Oceanogr. (USA), vol.13, no.4, p.648-62 (April 1983).

Discusses the spatial character of mesoscale temperature variability as observed in six midlatitude multiship expendable bathythermograph (XBT) surveys, two from the North Pacific and four from the North Atlantic. These surveys sample mid-ocean regions as well as regions adjacent to the western boundary currents of both subtropical gyres. Mesoscale characteristics exhibit substantial changes between surveys, between ship tracks within each survey and between different portions of individual ship tracks. These results suggest that a single XBT section across a region is unlikely to represent the range of variability within that region satisfactorily. Fluctuations below the mixed layer are strongly vertically correlated, but surface temperatures are not well correlated with those below the mixed layer. (21 refs.)

110453 Stability of free surface Ekman layers. G.F.Spooner (Ocean Dynamics Branch, Naval Res. Lab., Washington, DC, USA).

J. Phys. Oceanogr. (USA), vol.13, no.4, p.663-77 (April 1983).

The stability of free surface, laminar Ekman layers is examined for both the homogeneous and the two-layer case. The eigenvalues of the homogeneous case depend upon the wavenumbers α and γ and the Reynolds number Re. Those of the two-layer case depend upon α, γ, Re, the depth of the top layer, and the parameter $Fr^*=g\delta(\rho^*-\rho)/(U_s{}^2\rho)$, where g is the acceleration of gravity, δ is the Ekman scaling depth, ρ and ρ^* are the densities of the top and bottom layers, respectively, and U_s is the mean speed at the surface. The behaviour of the inflection point mode and the parallel mode of instability is examined as a function of the independent parameters in both cases. (16 refs.)

110454 A numerical study of the effects of coastline geometry on wind-induced upwelling in the Gulf of Lions. Bach-lien Hua (Museum Nat. d'Histoire Naturelle, Paris, France), F.Thomasset.

J. Phys. Oceanogr. (USA), vol.13, no.4, p.678-94 (April 1983).

An attempt is made to explain the fixed locations of coastal upwelling centres in the Gulf of Lions as a function of the coastline geometry alone. The semi-implicit numerical model, based on two-layer shallow water equations, uses a spatial discretisation with triangular finite elements. Vertical mixing is shown to play an important role in determining the final shape of the upwelling centres. It is conjectured that an observed upwelling filament results from the straining and stretching of a coastal upwelling centre by the observed anticyclonic circulation further offshore. (18 refs.)

110455 Hydraulic control and flow separation in a multi-layered fluid with applications to the Vema Channel. N.G.Hogg (Woods Hole Oceanographic Instn., Woods Hole, MA, USA).

J. Phys. Oceanogr. (USA), vol.13, no.4, p.695-708 (April 1983).

Observations from a recent field experiment in the Vema Channel are briefly described. These show a remarkable change in the configuration of isopycnal surfaces within the channel and the development of thick, nearly homogeneous regions near the bottom which are capped by sharp vertical gradients. Contrary to previous speculation that these 'bottom boundary layers' result from enhanced vertical mixing, a dynamical mechanism is explored. This involves the hydraulic adjustment of an inertial, semi-geostrophic flow to the channel geometry. First, an active two-layer flow in a rectangular geometry is studied to show that internal flow separation can occur when the flow is accelerated sufficiently by a narrowing channel. Almost always this separation accompanies hydraulic control: the slowest upstream moving Kelvin wave is stopped and upstream and downstream states are not symmetric with respect to the channel width. An active three-layer flow with a variable bottom profile is then presented as a more accurate model of the Vema Channel. (12 refs.)

110456 Lagrangian current measurements within the eastern margin of a warm-core Gulf Stream ring. J.J.Bisagni (US Naval Underwater Systems Centre, Newport, RI, USA).

J. Phys. Oceanogr. (USA), vol.13, no.4, p.709-15 (April 1983).

Two satellite-tracked buoys drogued at 10 m depth were deployed within shelf water, close to the shelf/slope front in late summer 1980. Position and sea-surface temperature data from the two buoys were combined with surface-water mass analysis based on high resolution infrared satellite imagery. Buoy trajectories and surface-water mass analysis suggest that both buoys traversed a region of shelf water while moving to the southwest at less than 25 cm s^{-1}. Stronger currents up to 54 cm s^{-1} from warm-core ring 80-A were encountered near 38°N latitude. These currents caused the buoys to move anticyclonically along the ring's eastern margin within a well defined shelf-water entrainment. Buoy sea-surface temperatures and positions showed good correlation with frontal boundaries based on satellite imagery. Volume transport of the ring entrainment was estimated to be 1.5×10^5 m^3 s^{-1} (4700 km^3 $year^{-1}$). (23 refs.)

110457 Topographic rectification of tidal currents. W.R.Young (Univ. of California, San Diego, CA, USA).

J. Phys. Oceanogr. (USA), vol.13, no.4, p.716-21 (April 1983).

The rectification of oscillatory tidal currents on the sloping sides of a low submarine bank is discussed using the moment method. In the present problem the moment method is applied to the barotropic potential vorticity equation linearised about an oscillatory, spatially uniform tidal velocity. To apply the method it is necessary to assume that the topography produces only a small change in depth. The method economically provides the most important qualitative properties (e.g., transport, location and width) of the time averaged current. It is shown that harmonic truncation correctly predicts the transport and location of the rectified current when the bank is low. However if the width of the bank is much less than a tidal excursion distance, harmonic truncation may give a very mistaken impression of the width of the rectified current. (12 refs.)

110458 Mass, heat, salt and nutrient fluxes in the South Pacific Ocean. C.Wunsch (Dept. of Appl. Maths. & Theoretical Phys., Univ. of Cambridge, Cambridge, England), D.Hu, B.Grant.

J. Phys. Oceanogr. (USA), vol.13, no.5, p.725-53 (May 1983).

An inverse method is applied to the Scorpio sections spanning the subtropical gyre of the South Pacific. In addition to constraints upon geostrophic fluxes of mass and salt, constraints are written for silica, oxygen and 'PO', and the Ekman fluxes and divergence are accounted for explicitly. Nutrient constraints contribute significantly to the system information with oxygen containing information independent of 'PO'. Attention is focused on zonally integrated quantities that are insensitive to differences in modeling assumptions. Overall interior flows are dominated by an equatorward flux of bottom water, a poleward return flow at mid-depths, equatorward flow of circumpolar intermediate water and a convergence of surface waters. The zonal average vertical velocity appears to be everywhere downward with the bottom water entraining fluid from above. The net meridional fluxes of silica, phosphate, oxygen and fresh water are indistinguishable from zero. (48 refs.)

110459 Development of a simple upper-ocean and sea-ice model. D.Pollard, M.L.Batteen, Young-June Han (Climatic Res. Inst., Oregon State Univ., Corvallis, OR, USA).

J. Phys. Oceanogr. (USA), vol.13, no.5, p.754-68 (May 1983).

Results are described for three simple numerical models of the upper ocean and sea ice with prescribed atmospheric forcing. The ability of each model version to simulate the observed sea surface temperature is assessed as a basis of comparison for future coupled experiments with atmospheric GCMs. The upper-ocean model versions range from a slab of fixed thickness to a variable-depth mixed layer above a variable exponential temperature gradient representing the seasonal thermocline. Sea-ice thickness is determined thermodynamically by local melting or accretion, and the effects of ice transport and leads are neglected. Each version is tested by integrating to equilibrium with horizontal advection neglected, using monthly climatological atmospheric data for a selected north-south section in the mid-Pacific Ocean and the results for different model versions are compared with each other and with available observations. (55 refs.)

110460 Self-advection of density perturbations on a sloping continental shelf. Ping-Tung Shaw, G.T.Csanady (Woods Hole Oceanographic Instn., Woods Hole, MA, USA).

J. Phys. Oceanogr. (USA), vol.13, no.5, p.769-82 (May 1983).

Bottom water movement on the continental shelf is modeled by the nonlinear interaction between long-shore bottom geostrophic flow and the density field. Bottom geostrophic velocity, subject to linear steady momentum equations with linear bottom friction, can be generated by along-isobath density variations over a sloping bottom. At the same time, the density field is slowly advected by the velocity field. Away from boundary layers, the interplay is governed by Burgers' equation, which shows the formation and self-propulsion of strong density gradients along an isobath. The problem is further investigated by solving the governing equations numerically. Under forcing by localized surface cooling, the flow in the mid-shelf region shows the characteristics of the solution of Burgers' equation. The theory sheds light on bottom water movements in the Adriatic Sea, over the Antarctic continental shelf, and in the Middle Atlantic Bight. It also describes the dispersion of river water and dense water outflow on the shelf. (29 refs.)

110461 Pressure fluctuations on the open-ocean floor off the Gulf of California: tides, earthquakes, tsunami. J.H.Filloux (Scripps Instn. of Oceanography, Univ. of California, San Diego, La Jolla, CA, USA).

J. Phys. Oceanogr. (USA), vol.13, no.5, p.783-96 (May 1983).

The paper supplements Filloux (1980) on sea-floor pressure observations conducted with a sensitive though not 'perfectly' stable transducer. A variety of examples are used to demonstrate that a wide range of research subjects in the fields of physical oceanography and submarine geophysics can be studied with measurements from Bourdon-tube pressure sensors combined with inherently linear and friction-free electrooptical feedback. Results from a three-month experiment in the Pacific Ocean, off the entrance of the Gulf of California, are presented. The tidal behavior at the experimental site is representative of the open ocean conditions that control the co-oscillation of the Gulf of California. At supra-tidal frequencies the pressure signature of local surface waves is significant. The occurrence during the experiment of the Petatlan earthquake (14 March 1979) provided the opportunity to record a tsunami traveling in deep water. The seismic disturbance from the earthquake was also recorded. At the highest frequencies the author examines instrumental noise, the deep pressure signature of surface waves and swells, and the possibility of monitoring microseism activity. (41 refs.)

110462 Determination of the pressure along a closed hydrographic section. I. The ideal case. P.Welander (School of Oceanography, Univ. of Washington, Seattle, WA, USA).

J. Phys. Oceanogr. (USA), vol.13, no.5, p.797-803 (May 1983).

The pressure along a closed hydrographic section can be correctly calculated from density data, in the ideal case of perfectly steady, geostrophic, density-conserving flow; and from dense, error-free data, excluding certain degenerate cases. A corresponding practical method, aimed at an estimate of the pressure from real hydrographic data, is designed. The calculation is made by a minimization of the volume enclosed by the surface $B=F(\rho, P)$ in the P-ρ-B space, where ρ is the density, $P=f\rho_z$ the potential vorticity, and $B=B^*+p_0$ the Bernoulli function, split in a known baroclinic part B^* and an unknown pressure p_0, defined at a chosen depth z_0. The minimization is made under free variation of $p_0(s)$, as a function of the tangential coordinate s; the minimum volume is zero under the ideal conditions. Practically, one minimizes a moment rather than the volume, with identical results in the ideal case. (5 refs.)

110463 Doppler sonar observations of internal waves: wave-field structure. R.Pinkel (Scripps Instn. of Oceanography, Univ. of California, San Diego, La Jolla, CA, USA).

J. Phys. Oceanogr. (USA), vol.13, no.5, p.804-15 (May 1983).

During May of 1980 an internal-wave-measurement experiment was conducted from the Research Platform FLIP off the California coast. The author discusses an 18-day sequence of velocity profiles obtained during the experiment using a pair of Doppler sonars. The sonars profile to a depth of 700 m, with approximately 20 m depth resolution. Plots of the velocity and shear field indicate the dominance of near-inertial motions. Much of the near-inertial variance can be ascribed to a few identifiable wave groups. The progress of these groups can be tracked for many days. The shear at the base of the mixed layer is often dominated by near-inertial motions propagating vertically through the thermocline rather than wind-forced motions in the mixed layer itself. The wisdom in modeling the low-frequency wave field as an 'equivalent continuum' is questioned. (15 refs.)

110464 On the theory of the equilibrium range in the spectrum of wind-generated gravity waves. S.A.Kitaigorodskii (Dept. of Earth & Planetary Sci., Johns Hopkins Univ., Baltimore, MD, USA).

J. Phys. Oceanogr. (USA), vol.13, no.5, p.816-27 (May 1983).

It is shown that an exact analog of Kolmogoroff's spectrum in a random field of weakly nonlinear surface gravity waves gives a spectral form for frequency spectra $S(\omega)\sim\omega^{-4}$ in close agreement with the results of recent observational studies. The proposed theory also indicates the existence of a 'transitional' range of wavenumbers (frequencies) where the deviation from Kolmogoroff's equilibrium is due to gravitational instability (wave breaking). Because of this it is suggested that the equilibrium form for the spectrum of wind-generated waves has two asymptotic regimes: Kolmogoroff's and Phillips' (1958) type of equilibrium with a relatively rapid transition from the first to the second. (18 refs.)

110465 Four views of a portion of the North Atlantic subtropical gyre. L.Armi (Scripps Instn. of Oceanography, La Jolla, CA, USA), H.Stommel.

J. Phys. Oceanogr. (USA), vol.13, no.5, p.828-57 (May 1983).

Data from four cruises to the 'β-triangle' centered at 27°N, 32°30′W are smoothed by fitting second-degree polynomials at each of about 30 different density surfaces. The density intervals are $\Delta\sigma_p=0.3$ per mille, corresponding to about 50 db intervals in pressure. From the polynomials, a determination is made of central values, horizontal derivatives and Laplacians of the fields of pressure, salt, oxygen and dynamic height. In addition, maps of the fits and deviations of each station from the smoothed fits are produced. From the steady advective diffusive equation and the smoothed fits to the salt, oxygen and dynamic height fields, the lateral isopycnal diffusivity is estimated. The mixing length of the horizontal turbulence is found. (32 refs.)

110466 Upper ocean thermal variability in the Sargasso Sea July 1977-July 1978: the POLYMODE XBT program. D.E.Harrison (Dept. of Meteorology & Phys. Oceanography, MIT, Cambridge, MA, USA), R.H.Heinmiller.

J. Phys. Oceanogr. (USA), vol.13, no.5, p.859-72 (May 1983).

Discusses the upper ocean mesoscale temperature variability field as sampled by XBTs in the joint US-USSR POLYMODE Synoptic Experiment during July 1977 to July 1978. There is a 'background' persistent, relatively weak and rather large-scale pattern of variability, of alternating warm and cold areas which propagate nearly westward. For the background, very little point correlation between surface temperatures and temperatures beneath the mixed layer is found, but sub-mixed-layer temperatures above and below the '18°C water' show negative correlation. The authors find a number of smaller scale, apparently discrete, features which are somewhat more intense than the background. They exhibit little consistency in direction of propagation, and pattern propagation, rather than pattern evolution, as generally observed. The time-average depth field of the 15°C isotherm exhibits spatial variations comparable in magnitude to its pointwise standard deviation values. (14 refs.)

110467 Interannual variation in net heating at the surface of the tropical Pacific Ocean. B.C.Weare (Dept. of Land, Air & Water Resources, Univ. of California, Davis, CA, USA).

J. Phys. Oceanogr. (USA), vol.13, no.5, p.873-85 (May 1983).

Interannual variations of net surface heating of the tropical Pacific Ocean are analyzed for the period 1957-76. Special emphasis is given to exploring the relationship between these variations and those in sea temperature associated with El Nino/Southern Oscillation. The analyses include eigenvector analysis, composites of the net heating for various phases of El Nino, and time series analysis of various measures of the variability. The results indicate large scale patterns of variability dominated by time scales greater than one year. A link between the large-scale variations of sea temperature and net surface heating is evident from each set of analyses. It is hypothesized that net surface heating contributes to the development of the early stages of an El Nino warm period. (24 refs.)

110468 Modeling the mean barotropic circulation in the Bay of Fundy and Gulf of Maine. D.A.Greenberg (Atlantic Oceanographic Lab., Bedford Inst. of Oceanography, Dartmouth, Nova Scotia, Canada).

J. Phys. Oceanogr. (USA), vol.13, no.5, p.886-904 (May 1983).

Two two-dimensional, nonlinear numerical models are used to study the residual barotropic circulation generated by tides and steady winds in the Bay of Fundy and Gulf of Maine. The first, a multi-grid model, is used to examine the Bay of Fundy with a coarse look at the Gulf of Maine. The circulation in the upper Bay of Fundy is predominantly tidally driven. Steady wind stresses have some effect on the strength of these currents but little effect on the pattern. The counterclockwise gyre, observed in the body of the Bay of Fundy, is not reproduced in the model. The second model covers the lower Bay of Fundy and the Gulf of Maine with a single fine grid and is used to look at details in the Gulf of Maine. A clockwise circulation around Georges Bank and Nantucket Shoals is clearly indicated from tidal forcing alone, as is a gyre over the shallow part of Browns Bank. Different steady wind-stress fields give rise to variations in current strength and current patterns. (29 refs.)

110469 An observation of frontal wave development on a shelf-slope/warm core ring front near the shelf break south of New England. S.R.Ramp (Nat. Marine Fisheries Service, Northeast Fisheries Center, Woods Hole, MA, USA), R.C.Beardsley, R.Legeckis.
J. Phys. Oceanogr. (USA), vol.13, no.5, p.907-12 (May 1983).
Small-scale waves have been observed near 40°N, 68°30′W in specially enhanced satellite imagery of a strong temperature front formed in May 1979, between the shelf/slope-water front and warm core ring 79-B. These frontal waves had a wavelength of 23 ± 4 km, an eastward propagation speed of 32 ± 4 km day^{-1}, and a growth rate (*e*-folding time) of 17.5 h (12-19 h). These satellite data plus current-velocity and hydrographical data gathered from the Nantucket Shoals Flux Experiment (NSFE79) allow comparison of the observed growth rate with theoretical predictions based on the assumption of a Margules front and the instability model of Orlanski (1968). This comparison suggests that the observed frontal waves were due primarily to horizontal-shear instability and derived their energy from the mean flow structure across the front in the presence of ring 79-B. (8 refs.)

110470 Sea ice thickness distribution in Fram Strait. P.Wadhams (Scott Polar Res. Inst., Univ. of Cambridge, Cambridge, England).
Nature (GB), vol.305, no.5930, p.108-11 (8 Sept. 1983).
HM nuclear submarine Sovereign has obtained the first synoptic measurements of the ice thickness distribution in Fram Strait, the main outflow from the Arctic Ocean. The ice nearest the ice edge is of quite different character from ice in the interior of the Strait, with a greater proportion of first-year ice and less pressure ridging. An estimate of the ice flux through Fram Strait can be made from the distribution of mean ice drafts. (26 refs.)

110471 Reflection and refraction of topographic Rossby waves. V.M.Volosov (Shirshov Inst. of Oceanology, Acad. of Sci., Moscow, USSR).
Oceanology (USA), vol.22, no.2, p.117-20 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
The linear approximation of the theory by Volosov (1976, 1980) and Rhines et al. (1973) is modified to investigate the reflection and refraction of barotropic topographic Rossby waves in a homogeneous ocean with a moderate-depth gradient and small-scale anisotropic bottom relief. The amplitudes of the reflected and refracted waves and the particle velocities are found, and the transmission and reflection coefficients are calculated. Special cases of propagation without reflection, total internal reflection and the generation of exponentially damped waves are considered. A physical interpretation of the results is given and some generalizations are indicated. (9 refs.)

110472 The effect of synoptic eddies on the heat content distribution in the Sargasso Sea. N.P.Bulgakov, A.B.Polonskiy (Marine Hydrophys. Inst., Acad. of Sci., Sevastopol, Ukrainian SSR).
Oceanology (USA), vol.22, no.2, p.121-3 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
The data collected on expeditions of the Marine Hydrophysical Institute teams under the POLYMODE program are used to analyze the horizontal distribution of heat content of the active and baroclinic layers of the ocean on synoptic scales. (8 refs.)

110473 Structure of the equatorial currents in the central and western Pacific. V.A.Bubnov (Shirshov Inst. of Oceanology, Acad. of Sci., Kalingrad, USSR), V.D.Yegorikhin, A.S.Osadchiy.
Oceanology (USA), vol.22, no.2, p.124-6 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
The vertical structure of currents at the equator is analyzed from measurements made in February-April 1980 at two stations in the central Pacific and three stations in the western Pacific. A typical dynamic structure of three zonal flows was observed in the upper 700 m layer: the south equatorial current, the Cromwell current and the westward intermediate equatorial current. In the western Pacific a well-defined double-core structure of the subsurface equatorial countercurrents was recorded. Its formation is due to the variable wind regime. (13 refs.)

110474 Effect of compressibility of seawater in current calculations. V.V.Guretskiy (Arctic & Antarctic Res. Inst., Leningrad, USSR).
Oceanology (USA), vol.22, no.2, p.127-9 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
The effect of seawater compressibility on current calculations is analyzed. The fields of total integral circulation in the Southern Ocean obtained from a diagnostic model with and without correction for the seawater compressibility are presented. The analysis shows that when a horizontal temperature inhomogeneity is present at depth, correction for the pressure in the seawater density calculation increases the calculated horizontal density gradients and current velocities. (8 refs.)

110475 Model of the climatic spectrum of internal waves in the ocean. A.S.Samodurov (Marine Hydrophys. Inst., Acad. of Sci., Sevastopol, Ukrainian SSR).
Oceanology (USA), vol.22, no.2, p.130-2 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
Expressions for the space-time energy spectra of internal waves in the ocean are obtained by the analysis of the spectral wave equation in the ray approximation. (7 refs.)

110476 Concerning the mechanisms of generation of fine structure of the current velocity field in the ocean. V.M.Zhurbas (Shirshov Inst. of Oceanology, Acad. of Sci., Moscow, USSR).
Oceanology (USA), vol.22, no.2, p.133-6 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
Observational data on the fine structure of the velocity field of currents in the surface layer of the ocean over the vertical scale range of 16 to 24 m, obtained with acoustic velocity profilers during the 22nd cruise of R/V Dmitriy Mendeleyev (Station 1798) are presented. The measurements were performed by repeated soundings in the 20 to 700 m layer. It was found that the spectral density of the fine structure of the velocity field can be described by the relationship $S_v(m) \sim m^{-3}$, where m is the vertical wave number, the RMS deviations of current velocity σ_v vary with depths as $\sigma_v \sim N(z)$ at $N(z) \gtrsim 10^{-2}$ rad/sec (layer with high density gradients, $N(z)$ is the mean Vaisala-Brunt frequency profile) and $\sigma_v \sim N^{1/2}(z)$ at $N(z) < 10^{-2}$ (main pycnocline). It is shown that these properties of the fine structure of the current velocity field in the layer with high velocity gradients can be attributed to mechanisms of internal waves and geostrophic turbulence, whereas the comparison of experimental data in the main pycnocline with analytic expression is made difficult by the significant error of velocity measurements. (12 refs.)

110477 Effect of surfactants on wind-driven waves. A.V.Arkharov, S.A.Petrichenko, V.D.Pudov (Inst. of Experimental Meteorology, Obninsk Kiev State Univ., Kiev, Ukrainian SSR).
Oceanology (USA), vol.22, no.2, p.137-9 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
The results of an experimental study of the effect of surfactants on the development of wind-driven waves are presented. It is shown that with a surfactant film on the surface, no waves are generated at velocities of up to 3 to 5 m/sec. At wind speeds of 12 m/sec the waves are accelerated more rapidly on a surfactant-coated surface, but the intensity of waves is lower than on an uncoated one. (4 refs.)

110478 Measurement of volume scattering of sound in the ocean with a deep-water acoustic instrument. Yu.Yu.Zhitkovskiy, V.A.Mozgovoy, V.V.Savel'yev (Shirshov Inst. of Oceanology, Acad. of Sci., Moscow, USSR).
Oceanology (USA), vol.22, no.2, p.150-1 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
A study of volume scattering of sound in the central Atlantic by means of a deep-water acoustic instrument system showed that the sound scattering layer observed at depths of 500 to 600 m consists of individual 'targets', apparently fish shoals. The coefficients of volume scattering of sound inside a given 'target' can exceed by two orders of magnitude its means value for a given layer. (1 ref.)

110479 An experimental study of the mean velocity distributions of translational flows in the coastal zone of the sea. S.A.Yefremov (Shirshov Inst. of Oceanology, Acad. of Sci., Moscow, USSR).
Oceanology (USA), vol.22, no.2, p.197-8 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
The possibility of the existence of velocity extrema within a flow is verified experimentally. A theory of these extrema is presented. Numerical estimates show that such a velocity distribution in translational flows may occur in the presence of mutually opposing gradient and wind-driven currents. (1 ref.)

110480 Ocean acoustic tomography: rays and modes. W.Munk, C.Wunsch (Dept. of Appl. Math. & Theoretical Phys., Univ. of Cambridge, Cambridge, England).
Rev. Geophys. & Space Phys. (USA), vol.21, no.4, p.777-93 (May 1983).
The authors have measured perturbation of the sound speed (temperature) field within an ocean volume by repeated acoustic transmissions through the volume along may different ray paths. The data set consisted of ray travel time perturbations, and the sound field was obtained by inverse theory. The method is extended to cases (e.g. the 'axial' ocean near a sound speed minimum) where ray theory is not applicable or not convenient. This is done by including in the data set the frequency perturbation of lower modes. The procedures are illustrated for bilinear and quadratic sound channels, and for a cosh z profile. (30 refs.)

110481 Mean latitudinal water and temperature values for the World Ocean. L.A.Strokina (State Hydrologic Inst., USSR).
Sov. Meteorol. & Hydrol. (USA), no.4, p.40-3 (1982). Translation of: *Meteorol. & Gidrol. (USSR)*, no.4, p.50-5 (1982).
Presents mean long-term zonally averaged values of the water and air temperature at the surface of the World Ocean for each month of the year. The relationships of these temperatures for various latitudinal zones are examined. (19 refs.)

92.20 INTERDISCIPLINARY ASPECTS OF OCEANOGRAPHY

110482 Oil slick drift trajectories for hypothetical spills in the Arabian Sea. P.G.Kurup (Dept. of Marine Sci., Univ. of Cochin, Cochin, India).
Indian J. Mar. Sci., vol.12, no.1, p.1-10 (March 1983). [received: Sept. 1983]
The location of oil slick deposition on the shore and the duration available for weathering have been predicted using monthly wind and current data. Of the 732 spills studied, 135 spills may pollute the Indian coast with varying intensity. The period May-September provides more chances of severe oil deposition on the west coast of India. Slicks from the farthermost spills considered (370 km offshore) takes only 14 d to reach the Indian shore during July. A series of 12 monthly charts have been produced, which enables forecast of the slick movement and allows some qualitative inferences on the severity of damage these spills can cause on the shores. (13 refs.)

110483 Studies for dispersion of radioactive effluents from an atomic power plant in coastal waters at Kalpakkam. K.V.K.Nair, M.A.R.Iyengar, S.Ganapathy, V.Kannan, M.P.Rajan, P.R.Kamath (Environmental Survey Lab., Bhabha Res. Centre, Kalpakkam, India).
Indian J. Mar. Sci., vol.12, no.1, p.11-16 (March 1983). [received: Sept. 1983]
Drift bottle and dye discharge studies from a jetty at a point 180 m (A) away from the shore showed that the discharges moved shoreward and breaking waves appeared to be the dominant factor affecting water movement. Similar studies at 270 (B) and 320 m (C) from the shore showed that wind and wind driven currents were the factors affecting water movement. Detailed observations at B showed it to be the most suitable location for the discharge of radioactive effluents. Studies on vertical distribution of density showed density stratification during the rainy season; density stratification is likely to be strengthened with warm water discharges. (6 refs.)

110484 Revised parameters for modeling the transport of PCB components across an air water interface. R.F.Bopp (Lamont-Doherty Geological Obs., Columbia Univ., Palisades, NY, USA).
J. Geophys. Res. (USA), vol.88, no.C4, p.2521-9 (20 March 1983). [received: Sept. 1983]
A number of revisions of the data base and conceptualizations utilized in air-water transport models for PCB components are suggested. The most significant of these involves the assignment of physical chemical properties on the basis of degree of chlorination. The effect of temperature on the rate of transport is also discussed. The revised model is tested on a number of natural situations and compared with available data. (48 refs.)

110485 Property distributions and deep chemical measurements within the western Gulf of Mexico. J.M.Morrison, W.J.Merrell,Jr. (Dept. of Oceanography, Texas A&M Univ., College State, TX, USA), R.M.Key, T.C.Key.
J. Geophys. Res. (USA), vol.88, no.C4, p.2601-8 (20 March 1983). [received: Sept. 1983]
Distribution of salinity, dissolved oxygen, nitrate, phosphate, and silicate are presented for the western Gulf of Mexico in 1978. Plots of chemical concentration versus potential density are used to identify the presence of gulf water, tropical Atlantic central water, Antarctic intermediate water, Caribbean midwater, and upper North Atlantic deep water within the upper 1600 m of the western Gulf of Mexico. Property distributions are closely related to the current regime described by Merrell and Morrison (1981). Tritium, carbon 14, radium 226, and ranon 222 values that were taken at a deep station located at 23°02′N and 92°28′W are also presented. (15 refs.)

110486 Palladium and nickel in north-east Pacific waters. .Dong Soo Lee (Scripps Instn. of Oceanography, Univ. of California, San Diego, La Jolla, CA, USA).
Nature (GB), vol.305, no.5929, p.47-8 (1 Sept. 1983).
Reports the first palladium profiles in marine water and sediment columns. Palladium concentration in the water column of the north-east Pacific increases from 0.18 pmol kg^{-1} at the surface to 0.66 pmol kg^{-1} in deep waters. There is a strong co-variance between palladium and nickel, which implies similar biogeochemical sediments from the Palace Moat, Tokyo, Japan, is observed and is perhaps a consequence of palladium usage in automobiles. (17 refs.)

110487 Rare earth elements in seawater near hydrothermal vents. G.Klinkhammer, H.Elderfield (Dept. of Earth Sci., Univ. of Leeds, Leeds, England), A.Hudson.
Nature (GB), vol.305, no.5931, p.185-8 (15 Sept. 1983).
Rare earth element (REE) patterns in the deep Pacific are strongly depleted in the lighter elements and have a large negative cerium anomaly. These REE patterns and associated concentration-depth profiles are maintained by regeneration in deep waters modified by preferential scavenging of the lighter elements. Scavenging by iron- and manganese-rich hydrothermal plumes might explain why vast areas of sediments far removed from spreading centres contain a metalliferous component. (22 refs.)

110488 Study of the temperature dependence of the rate of oxygen exchange across an air-water interface. N.A.Mel'nichenko (Far Eastern State Univ., Vladivostok, USSR), V.I.Chizhik.
Oceanology (USA), vol.22, no.2, p.157-61 (1982). Translation of: *Okeanologiya (USSR)*, vol.22, no.2 (1982). [received: Aug. 1983]
The pulse nuclear magnetic resonance method (relaxation technique) was used for measurement of rates of diffusive oxygen exchange across air-water (both distilled and sea) interfaces in the temperature range of 0 to 35°C. This rate proved virtually independent of water salinity and direction of diffusion (air to water, or vice versa). Its temperature dependence obey Arrhenius' law. (13 refs.)

110489 Delineation of seasonal changes of chlorophyll frontal boundaries in Mediterranean coastal waters with Nimbus-7 Coastal Zone Color Scanner data. D.Caraux, R.W.Austin (Visibility Lab., Scripps Instn. of Oceanography, La Jolla, CA, USA).
Remote Sensing Environ. (USA), vol.13, no.3, p.239-49 (July 1983).
The seasonal changes in chlorophyll-like pigment distribution in the North-western Mediterranean Sea (Gulf of Lions) were monitored during the year 1979. Data were collected from the Coastal Zone Color Scanner (CZCS), carried on the Nimbus-7 satellite. A series of cloud-free images covering the whole year was selected and processed to evaluate chlorophyll-like pigment concentrations. The upwelling subsurface radiance of the ocean (L_{ss}) was extracted from the apparent upwelling signal reaching the satellite sensor using an algorithm removing atmospheric effects. Chlorophyll-like pigment concentration was then derived from L_{ss} in different wavelengths. Characteristic boundaries between water masses with different phytoplankton content were obtained. The results demonstrate that phytoplankton distribution is a good indicator of seasonal variations of oceanic fronts. Features such as coastal upwellings, cyclonic eddies, or plume of the Rhone river could be monitored. (21 refs.)

110490 Space-time variability of petroleum hydrocarbons in waters of the north Atlantic. E.A.Sobchenko, I.G.Orlova, V.A.Mikhailov, R.I.Lisovskii (State Oceanographic Inst., Odessa, USSR).
Sov. Meteorol. & Hydrol. (USA), no.4, p.44-51 (1982). Translation of: *Meteorol. & Gidrol. (USSR)*, no.4, p.56-65 (1982).
Results of observations of oil pollution of surface waters of the North Atlantic carried out within the framework of the IOC-WMO pilot project during a three-year period (1977-1979) are presented. An assessment of the current level of oil pollution of the investigated region and background level of the dissolved-emulsified fraction of petroleum hydrocarbons is given. The temporal (interannual) variability of various forms of oil pollution is examined. (14 refs.)

92.40 HYDROLOGY AND GLACIOLOGY

110491 Thermal response of unconfined ice shelves to climatic conditions. F.M.Williams, K.Hutter.
Acta Mech. (Austria), vol.48, no.3-4, p.131-46 (1983).
An analysis of the thermomechanical behavior of an ice shelf is presented. The mathematics is simplified by simulating the transverse temperature distribution by a realistic shape function thereby replacing the local energy equation by a time-dependent, total energy balance condition which accurately models the ocean-ice and ice-atmosphere heat exchange processes. The emerging steady state theory correlates a dimensionless combination of accumulation rate, horizontal strain rate and thickness with heat flux and surface temperature and shows fair agreement with published data. A time-dependent small perturbation analysis further shows that the criterion of stability of the solutions is expressible in terms of this dimensionless parameter. (14 refs.)

110492 On the area/depths relation of selected rainfall events. D.Schumann (Meteorologischer Dienst, Berlin, Germany).
Z. Meteorol. (Germany), vol.33, no.3, p.179-83 (1983). In German.
For 80 rainfall events, the decrease of the maximum point rainfall with increasing area is investigated for rainfall durations from 1 to 36 hours. The results show that both the range of the areal rainfall/point rainfall ratio between rainfalls of the same duration and the mean areal rainfall/point rainfall ratio for rainfalls of different duration are a distinct function of the rainfall duration. The relation between the area-depth ratio and the weather conditions is discussed. The author highlights the means for an operational use of the present results particularly for real-time purposes of meteorology and water management. (6 refs.)

110493 Ground-water microtemperature measurements, coseismic signals and atmospheric pressure effects. H.Shimamura (Lab. for Ocean Bottom Seismology, Geophysical Inst., Hokkaido Univ., Sapporo, Japan).
Ann. Geophys. (France), vol.1, no.3, p.235-8 (May-June 1983).
Very accurate temperature measurements of ground-water, with an accuracy better than 1/1000°C, have been made in about forty wells in Japan. Many coseismic signals, with amplitudes of 1-170 m°C, have been observed. They are generally consistent with magnitudes and distances of earthquakes. The observed microtemperature also shows a clear effect of the atmospheric pressure changes, where the observed temperature increases when the pressure decreases. The pressure coefficients varies for more than 100 times from well to well. Some possible precursors of earthquakes have also been recorded. The authors believe they are tracing the movements of ground-water through the microtemperature measurements, although the mechanism has not yet been exactly clarified. (2 refs.)

110494 The occurrence of lead in Antarctic recent snow, firn deposited over the last two centuries and prehistoric ice. C.F.Boutron (Lab. de Glaciologie et Geophys. de l'Environnement, CNRS, Grenoble, France), C.C.Patterson.
Geochim. & Cosmochim. Acta (GB), vol.47, no.8, p.1355-68 (Aug. 1983).
Concentrations of lead have been measured by ultraclean Isotope Dilution Mass Spectrometry in snow cores covering the last two centuries collected at an inland site in East Antarctica using an ultraclean all plastic hand operated auger and in a prehistoric blue ice block collected at an Antarctic coastal site. Lead contamination of 16 to 200 pg Pb/g existed on the outside of the snow cores, but the measured concentrations decreased more or less abruptly along a radius from the outside to the centers of the snow cores, establishing interior values in the 1 to 5 Pb/g range. The interior of the blue ice block appears not to have been significantly contaminated, and contains about 1.7 pg Pb/g. These new data show that most previously published data on lead in Antarctic snow and ice were in high positive error because of contamination during field sampling, laboratory analysis or both. The remote polar areas of the Southern Hemisphere are still affected by industrial lead pollution. Prehistoric Antarctic ice is shown to contain about 1 pg Pb/g natural excess lead above silicate dust lead. (40 refs.)

110495 Flow in alluvial-river curves. M.F.Ascanio (Inst. de Mecanica de Fluidos, Univ. Central de Venezuela, Caracas, Venezuela), J.F.Kennedy.
J. Fluid Mech. (GB), vol.133, p.1-16 (Aug. 1983).
Uniform flow in curved, wide, erodible-bed channels is formulated on the basis of the conservation of flux of moment-of-momentum, to obtain relations for the vertical distributions of radial-plane velocity and radial shear stress. The expression for the radial stress exerted on the bed is utilized in a force-equilibrium analysis of the moving bed layer to obtain relations for the average transverse slope of the bed and for the radial bed profile. The reduction of primary bed shear stress due to the net radial transport of streamwise momentum toward the outer (concave) bank is then calculated, by introduc-

ing the derived expressions for the velocity components into the momentum equation for the primary-flow direction. (15 refs.)

110496 Peculiarities of the nonequilibrium distribution of moisture in the freezing and thawing of disperse soils. Yu.S.Danielyan, P.A.Yanitskii (V.I. Muravlenko State Res. & Project Inst. of Petroleum & Gas Industry, Tyumen, USSR).
J. Eng. Phys. (USA), vol.44, no.1, p.76-82 (Jan. 1983). Translation of: *Inzh.-Fiz. Zh. (USSR)*, vol.44, no.1, p.91-8 (Jan. 1983). [received: Sept. 1983]
Presents the results of numerical simulation of the process of moisture migration in disperse soils with different regimes of freezing and with a view to the nonequilibrium effects accompanying the phase transformations of water. The results of simulation are compared with data of experimental investigations from the literature. (9 refs.)

110497 The bathymetry of Lakes King and Victoria. D.R.Blackman, J.B.Hinwood (Dept. of Mech. Engng., Monash Univ., Clayton, Victoria, Australia).
Proc. R. Soc. Victoria (Australia), vol.95, no.1-2, p.53-8 (30 June 1983).
The authors describe a recent bathymetric survey of part of the Gippsland Lakes. Charts giving the results are included. (4 refs.)

110498 Ice-age simulations with a calving ice-sheet model. D.Pollard (Climatic Res. Inst., Oregon State Univ., Corvallis, OR, USA).
Quaternary Res. (USA), vol.20, no.1, p.30-48 (July 1983).
Variations of ice-sheet volume during the Quaternary ice ages are simulated using a simple ice-sheet model for the Northern Hemisphere. The basic model predicts ice thickness and bedrock deformation in a north-south cross section, with a prescribed snow-budget distribution shifted uniformly in space to represent the orbital perturbations. An ice calving parameterization crudely representing proglacial lakes or marine incursions can attack the ice whenever the tip drops below sea level. The model produces a large ~100000-yr response in fair agreement with the $\delta^{18}O$ deep-sea core records. (43 refs.)

110499 Flood frequency analysis: a review of 1979-1982. N.P.Greis (Bell Labs., Holmdel, NJ, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.699-706 (April 1983).
Discusses the areas of (1) distributional analysis and (2) robust parameter estimation, and what might be called developments of potential in the area of (3) regionalized and geomorphologic approaches to the flood frequency problem. While the primary focus is on American work, the author includes some mention of non-American work when the contributions of American hydrologists can be seen more distinctly against a backdrop of global activity. (130 refs.)

110500 Surface water hydrology: on-line estimation. S.Sorooshian (Dept. of Hydrology & Water Resources, Univ. of Arizona, Tucson, AZ, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.706-21 (April 1983).
Discusses conceptual rainfall-runoff models, and systems-theoretic models. An attempt is made to highlight those problem areas that were addressed during the past four years (1979-1982) and those issues which are yet to be adequately resolved. (113 refs.)

110501 Surface water hydrology—runoff generation and basin structure. K.Beven (Dept. of Environmental Sci., Univ. of Virginia, Charlottesville, VA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.721-30 (April 1983).
Addresses the problem of developing a theory of the relationship between runoff generation and basin structure. It is suggested that the current generation of physically based models of basin hydrology cannot predict runoff generation in the field with any adequacy because they are not good descriptors of runoff processes, except under some special circumstances. Some of the complex factors contributing to runoff generation that lead to this conclusion are discussed. Special emphasis is placed on the problems posed by the spatial variability of soil characteristics to the application of physically based models. The way in which basin structure changes with spatial scale is then considered. (165 refs.)

110502 Urban hydrology. J.W.Delleur (School of Civil Engng., Purdue Univ., West Lafayette, IN, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.730-40 (April 1983).
Discusses hydrologic processes in urban areas, hydraulic conveyances, detention basins, combined sewer overflows, rainfall runoff models, data acquisition and the Nationwide Urban Runoff Program. (575 refs.)

110503 Progress in hydrodynamic modeling. Review of US contributions, 1979-1982. D.R.Lynch (Thayer School of Engng., Dartmouth Coll., Hanover, NH, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.741-54 (April 1983).
Discusses one and two dimensional modelling for vertically homogeneous hydrodynamics and in partially stratified hydrodynamics and stratified hydrodynamics. (183 refs.)

110504 Unsaturated soil water flow. R.E.Smith (Agricultural Res. Service, US Dept. of Agriculture, Fort Collins, CO, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.755-60 (April 1983).
Discusses research by United State's scientists published in journals during the nominal period 1979 to 1982, inclusive. Much excellent work published in the same journals by scientists from other countries has been passed over. The last half year 1982 could not be covered due to publication deadlines. For the same reason, research published in late 1978 has been included which was not discussed in the previous quadrennial report. The summary and bibliography are not exhaustive insofar as local institutional reports and journals not ordinarily dealing with the subject have not been searched through. (105 refs.)

110505 Ground water: a review. J.D.Bredehoeft (US Geological Survey, Menlo Park, CA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.760-5 (April 1983).
Groundwater hydrology is discussed including transport with chemical reactions, and the restorability of an aquifer which has been contaminated. (111 refs.)

110506 Research on snow and ice. R.G.Barry (Dept. of Geography, Univ. of Colorado, Boulder, CO, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.765-76 (April 1983).
Snow and ice distribution and remote sensing, sea ice dynamics, icebergs, glaciers, ice sheets, cryosphere-climate interactions and CO_2 effects in the atmosphere are discussed. (371 refs.)

110507 Chemical study of the Tama River. V. N.Kokubu, K.Suzuki, K.Motozima, A.Fujitsuka (Univ. of Electro-Communications, Tokyo, Japan).
Rep. Univ. Electro-Commun. (Japan), vol.33, no.2, p.239-45 (Feb. 1983).
For pt.IV see ibid., vol.33, no.1, p.43-8 (1982). The results of the determinations made in 1976 on Tama River water are reported. Ten sampling stations were the same as the preceding report in 1975. The water samples were collected from April 1976 to February 1977. The water temperature, pH value, redox potential, Na, K, Ca, Mg, F, Cl, SO_4, PO_4 and SiO_2 are determined. The variations of chemical composition of the river water and mutual relations of chemical constituents are discussed. Secular change of the river water quality from 1972 to 1973 is also described. (6 refs.)

110508 Turbulent structure of a natural density current in the region of its formation. Yu.G.Pyrkin, B.I.Samolyubov, A.A.Kuznetsov (Moscow State Univ., Moscow, USSR).
Sov. Meteorol. & Hydrol. (USA), no.4, p.52-8 (1982). Translation of: *Meteorol. & Gidrol. (USSR)*, no.4, p.66-74 (1982).
The turbulent structure of a stratified bottom flow in the zone of its formation under natural conditions is analyzed. The regularities of the spectral density of the turbulence of the flow (vertically and along the axis of the flow) are examined jointly with the profiles of the velocity, suspension concentration, temperature, and intensity of velocity fluctuations. (9 refs.)

110509 Investigation of the trend in the change in the volume of river discharge when estimating the normal annual runoff. E.A.Leonov, V.E.Leonov (State Hydrological Inst., USSR).
Sov. Meteorol. & Hydrol. (USA), no.4, p.59-66 (1982). Translation of: *Meteorol. & Gidrol. (USSR)*, no.4, p.75-84 (1982).
An analysis of the variations in the runoff of large rivers in the USSR shows that long-term trends in the volume of discharge are observed in runoff over many years. The change in runoff for phases of an increase and decrease of the volume of discharge is described well by the equation of a complex exponential function from values of the moving averages of the fixed normal annual runoff. The average duration of the increase and decrease of the discharge volume for an averaging period of T=50 years is 60-70 years. (18 refs.)

92.60 METEOROLOGY

(see also 43.28 Aeroacoustics and atmospheric sound)

110510 Observations of plume trajectories in the initial momentum influenced phase and parameterization of entrainment. K.T.Spillane (Div. of Atmospheric Phys., CSIRO, Mordialloc, Victoria, Australia).
Atmos. Environ. (GB), vol.17, no.7, p.1207-14 (1983).
Observations of plume trajectories from a 500 MW power station are reported for that phase of the rise influenced by the initial momentum flux. The mass-radius (a) growth law: $da/ds=0.16|(U_p-U_e\sin\phi)/U_p|+0.4(U_e\cos\phi)/U_p$, combined with Briggs' (1975) concept of an effective transverse momentum radius of 1.5a are shown to be suitable empirical concepts for modelling the entrainment of mass and momentum into the integral conservation equations of a wet-plume. Cross-wind pressure effects are shown to be small and related to R_0 but further trials at $R_0>5$ are required to confirm their dependence on R_0. Bifurcating plumes are as well described as conventional plumes with no evidence of stack wake effects at $R_0=1.8$. (S is the distance along the plume centre line which is at an angle ϕ to the vertical, U_p is the integral plume speed, U_e the wind speed and $R_0=U_p/U_e$ at the outlet). (29 refs.)

110511 A mesoscale atmospheric dispersion model for predicting ambient air concentration and deposition patterns for single and multiple sources. I.M.Ritchie, J.D.Bowman, G.B.Burnett (Minnesota State Planning Agency, St. Paul, MN, USA).
Atmos. Environ. (GB), vol.17, no.7, p.1215-23 (1983).
A mesoscale modified Gaussian model (MGM) that incorporates chemical oxidation of sulfur dioxide, dry deposition and precipitation scavenging for single and multiple sources is described. The model was verified in the range 5-250 km using 1.5-y monthly deposition data, 1-y of 24-h ambient air SO_2 data, and by comparison to two dispersion models. The calculated deposition rates which were compared to data collected around the Sudbury, Ontario, smelter complex were found to be within a factor of two to three of measured values depending on the averaging time. The comparison with two existing dispersion models gave results to within a factor of two. Sensitivity testing on the input parameters is also discussed. (22 refs.)

110512 Evaluation of an episodic regional transport model for a multi-day sulfate episode. D.A.Stewart, R.E.Morris, Mei-Kao Liu (Systems Applications Inc., San Rafael, CA, USA), D.Henderson.
Atmos. Environ. (GB), vol.17, no.7, p.1225-52 (1983).
An episodic regional transport model (RTM-II) is applied to a sulfate episode that occurred over the eastern third of the United States and southeastern Canada during the latter part of July 1978. An evaluation of the model performance is presented. Measurements for regional SO_2 and sulfate concen-

trations obtained from up to 54 monitoring stations geographically distributed throughout the modeling region are used. Simulation results are presented in a semi-quantitative manner through region-wide isopleth diagrams and time histories at individual stations. An analysis of the residuals over all measurements, the highest 50 per cent, and highest 10 per cent of the measurements is also included. (28 refs.)

110513 Atmospheric pollution studies at Kanpur—suspended particulate matter. V.P.Sharma, H.C.Arora, R.K.Gupta (Kanpur Zonal Lab., Nat. Environmental Engng. Res. Inst., Kanpur, India).

Atmos. Environ. (GB), vol.17, no.7, p.1307-13 (1983).

Kanpur is the largest industrial metropolis in the State of Uttar Pradesh, India. The atmosphere over the city is considerably polluted. An air quality evaluation study during 1973-1975 has yielded interesting results. This communication deals specifically with suspended particulate matter and its constituents collected from three sampling stations: Gwaltoli, Beconganj and Raipurwa. The study revealed that the 3-y average of the annual arithmetic means recorded for the three stations were 224, 256 and 298 $\mu g\ m^{-3}$, respectively. The constituents of the suspended particulate matter evaluated are benzene extractable matter, heavy metals namely iron, lead, copper, zinc and chromium and acid radicals namely sulphate and nitrate. Interesting observations have been recorded on the relationship of suspended particulate matter and benzene extractable matter. (7 refs.)

110514 Modeling of multiphase atmospheric aerosols. P.Saxena, C.Seigneur (Systems Applications Inc., San Rafael, CA, USA), T.W.Peterson.

Atmos. Environ. (GB), vol.17, no.7, p.1315-29 (1983).

Presents a mathematical model that describes the chemical composition and growth rate of atmospheric aerosols containing sulfate and nitrate, and that is applicable over the entire range of relative humidities. The model describes aerosols as consisting of an insoluble core, a soluble solid shell and an aqueous film. The chemical composition of the solid and aqueous aerosol phases in this model is governed by the following processes: (1) the chemical equilibria between the ambient gas and the aerosol liquid phases and between the aerosol liquid and the soluble solid phases; (2) the diffusion-limited condensation of H_2SO_4 and (3) the liquid-phase chemical reaction of SO_2. At low humidities the liquid phase may not be thermodynamically viable, in which case the model then treats the solid-phase/gas-phase equilibrium. (47 refs.)

110515 Some environmental effects of forest fires in interior Alaska. F.Eaton, G.Wendler (Geophys. Inst., Univ. of Alaska, Fairbanks, AK, USA).

Atmos. Environ. (GB), vol.17, no.7, p.1331-7 (1983).

The high variability of burning conditions and fuels, found in Alaskan forest fires, produces an associated complex emission of particulate matter. Histological evidence of some large particles has been found in the forest fire plumes as well as aerosols resulting apparently from gas-to-particle conversion. Particles analyzed with a scanning electron microscope and X-ray energy dispersive techniques show large variability in both physical and chemical characteristics. Optical measurements show forest fire smoke affects atmospheric turbidity regionally. Turbidity values presented which were measured in the plume from a forest fire 400 km from Fairbanks show values in excess of those found for heavily polluted urban regions. The particulate matter analysis showing irregular shapes and highly varied chemical composition displays the difficulty in radiative transfer calculations due to the assumptions of Mie theory. The nature of the aerosol size concentrations found in forest fire plumes also violates the assumption necessary for application of Angstrom's classic method of defining the turbidity coefficient and wavelength exponent. (27 refs.)

110516 Rotary spectral analysis for horizontal flow over central Europe. P.C.Werner (Meteorologischer Dienst, Potsdam, Germany).

Z. Meteorol. (Germany), vol.33, no.3, p.144-7 (1983). In German.

The vector of the large-scale geostrophic current over central Europe at the 500 and 1000 mb level is treated by an analysis of rotary spectra. The orientation of the major axis depends on the frequency of variation and shifts from a N-to-S direction with low frequencies to a NE-to-SW direction with higher frequencies, which is particularly distinct at the 1000 mb level. This shift is not monotonous at 500 mb nor very distinct, which affects the direction of rotation of the orientation of the major axis with increasing height. The inclination of the major axis at the horizontal level affects the meridional flux of momentum. (5 refs.)

110517 The cooling of the layer between 500 and 1000 mb. P.C.Werner (Meteorologischer Dienst, Potsdam, Germany).

Z. Meteorol. (Germany), vol.33, no.3, p.162-6 (1983). In German.

In the period 1957-1980, for which special values of the relative topography 500/1000 mb over central Europe are available, the author recognizes a cooling in the lower and middle troposphere for annual averages and for several months. This temperature decrease is compared with changes of the general circulation of the atmosphere, of the sea-surface temperature in the North Atlantic, of the global radiation, and of the temperature in Potsdam. Obviously, the circulation and with it the thermal advection are the predominant cause of the temperature decrease. (14 refs.)

110518 Analysis of the periodic variations of atmospheric pressure over Greece. T.J.Makrogiannis, B.E.Angouridakis, A.N.Bartzokas (Meteorological Inst., Aristotelian Univ. of Thessaloniki, Thessaloniki, Greece).

Z. Meteorol. (Germany), vol.33, no.3, p.167-75 (1983).

The yearly variation of atmospheric pressure over Greece shows a double fluctuation with a primary maximum in October-November and a primary minimum in July. The diurnal variation presents a double fluctuation, too, with a primary maximum around 10.00, a primary minimum around 16.00, a secondary maximum around 22.00 and a secondary minimum around 05.00 hours. All the three harmonic terms contribute positively to the formation of the final curve, and their contributions cover 87% of the total variance. Most important, and almost identical to the final curve, is the 2nd harmonic term. (10 refs.)

110519 Forecasting of radiation fog at Thessaloniki, Greece. V.E.Angouridakis, A.A.Flocas (Inst. of Meteorology & Climatology, Univ. of Thessaloniki, Thessaloniki, Greece).

Z. Meteorol. (Germany), vol.33, no.3, p.176-8 (1983).

The likelihood of the occurrence of radiation fog at Thessaloniki is examined. The fog point (T_f) for all recorded cases of radiation fog for the period 1950-1979 is estimated using Saunders' method. A stepwise multiple regression analysis of the T_f values and nine other parameters was carried out. The validity of the assumption of a linear relationship between T_f and the other parameters are examined and an equation derived. When T_f by Saunders' method differs by 1C° or less from the value calculated by the derived equation, there is a 98% probability that radiation fog will occur at Thessaloniki. (7 refs.)

110520 On puff models of turbulence diffusion at various scales of atmospheric movements. E.D.Syrakov (Faculty of Phys., Sofia Univ., Sofia, Bulgaria).

C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.5, p.631-4 (1983). (10 refs.)

110521 Modelling of mesometeorological transfer of pollution in SL while recording the interaction effect of admixture with underlying surface. C.D.Djolov (Faculty of Phys., Sofia Univ., Sofia, Bulgaria), D.E.Sirakov, D.L.Yordanov.

C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.5, p.639-42 (1983).

A modern method for the study of atmospheric diffusion is based on a statistical trajectory model, in which every continuously-acting source is approximated with a series of Lagrange puffs. These are summed up at certain time intervals and a concentration field is obtained. (3 refs.)

110522 CTR notes: simple method for estimating atmospheric absorption at 1 to 15 GHz. D.V.Rogers (Propagation Studies Dept., COMSAT Labs., Clarksburg, MD, USA).

COMSAT Tech. Rev. (USA), vol.13, no.1, p.157-63 (Spring 1983).

To obtain estimates of propagation impairments for system studies, it is often desirable to use simple, fast computational methods that require minimal site-specific meteorological data. Such a procedure has been developed for estimating atmospheric gaseous absorption at frequencies of 1 to 15 GHz and slant path elevation angles of 0° to 90°, using only frequency and elevation angle as input parameters. Analytic expressions are derived by curve fitting absorption data from the CCIR, assuming fixed values of surface water vapor concentration, ρ_s, and surface temperature, T_s. To illustrate the method, equations are obtained for values of ρ_s and T_s corresponding to two different standard atmospheric conditions. (2 refs.)

110523 Satellite observation of the Earth radiation budget. R.Kandel (Service d'Aeronomie CNRS, Verrieres-le-Buisson, France).

Contrib. Atmos. Phys. (Germany), vol.56, no.3, p.322-40 (1983).

The role of earth radiation budget studies in climate research is discussed with a number of examples in which detailed knowledge of the radiation budget is needed to improve understanding of climate dynamics. Since the advent of artificial satellites, global monitoring has become possible, but accuracy is limited by a number of problems: (i) spectral response and radiometric calibration; (ii) spatial resolution and angular sampling of the anisotropic radiation field; (iii) temporal sampling of diurnal and synoptic variations. Accomplishments since 1957 are reviewed. Current attempts, notably the Earth Radiation Budget Experiment, to improve the situation are described. (91 refs.)

110524 On the intensity of atmospheric convection. J.Oerlemans (Inst. of Meteorology & Oceanography, Univ. of Utrecht, Utrecht, Netherlands).

Contrib. Atmos. Phys. (Germany), vol.56, no.3, p.341-53 (1983).

Several runs with a numerical cloud model are discussed in order to quantify the effect of latent heat release on the development of convective activity. A scheme of the numerical results is constructed by means of a simple gradient system, with surface heat flux and moisture content as control parameters. For some range of these control parameters, two stable steady states occur. Internal forcing due to latent heat release creates the bifurcation. It is shown that for moist conditions convective activity tends to have a bimodal probability distribution. The practical consequence is that the short-range predictability of the weather is substantially reduced. (16 refs.)

110525 Determination of H_2O and CH_4 profiles from data of a nadir to limb scanning balloon-borne radiometer. H.Fischer, F.Fergg, D.Rabus, W.Volker (Meteorologisches Inst. Munchen, Munchen, Germany), H.J.Bolle.

Contrib. Atmos. Phys. (Germany), vol.56, no.3, p.354-74 (1983).

Nadir to limb radiance profiles were measured with a balloon-borne radiometer of special design and inverted to give vertical concentration profiles of water vapor and methane. (35 refs.)

110526 Supra-annual variations of geopotential heights in the subtropical stratosphere. A.H.Gordon (Flinders Inst. of Atmospheric & Marine Sci., Flinders Univ. of South Australia, Bedford Park, Australia).

Contrib. Atmos. Phys. (Germany), vol.56, no.3, p.375-81 (1983).

Mean monthly geopotential height data at 50 mb, 30 mb and 10 mb for latitudes 10°, 20°N and 30°N for the period 1957-78 were examined with a view to ascertaining whether they exhibited similar periodic behaviour to that documented by equatorial stratospheric wind observations. Results indicated that the geopotential heights possessed a variable periodicity, but a peak of about 3 years appeared highly significant at 50 mb and 10°N at all longitudes, matching the statistical significance of the quasibiennial oscillation itself. (10 refs.)

110527 Synoptic forcing of the planetary boundary layer: a case study from the PUKK experiment. E.Schaller (Meteorologisches Inst., Bonn Univ., Bonn, Germany).

Contrib. Atmos. Phys. (Germany), vol.56, no.3, p.382-98 (1983).

A case study of the nocturnal boundary layer is presented on the basis of PUKK data covering a period from September, 29th, 16^h to September, 30th, 1981, 8^h. Due to the intensification of a weak high pressure cell the wind was turning during that clear night from NW to SW and was thus changing its origin from sea to inland. This situation allows a study of the effects resulting from a synoptic forcing on the planetary boundary layer. It is demonstrated that on a time scale of one hour relatively large turbulent fluxes can be observed due to an increased horizontal advection. (11 refs.)

110528 Propagation characteristics at 35 and 78 GHz for spaceborn altimeters. D.Tarducci (CSELT, Torino, Italy).

CSELT Rapp. Tec. (Italy), vol.11, no.4, p.255-64 (Aug. 1983).

Frequency bands around 35 and 78 GHz have been recently suggested for satellite radar altimeters. As for any Earth-to-satellite radio link these frequencies are affected by atmospheric phenomena. As a first step, 'clean air' effects due to oxygen and water vapour contributions to the refractive index of the medium are examined. Atmospheric particle effects are considered: 'coherent' effects on the statistically averaged field (attenuation, phase rotation and 'in-band distortions' of the radar pulse); 'radar reflectivity' contributions to the received field; scintillation effects due to the particles 'random' motion. For each of these phenomena computations have been carried out for some ice and water cloud particles concentrations and for rains at different rates. Range errors are also computed: they seem to decrease with increasing frequency from 35 to 78 GHz. Finally, Doppler effects are found to be negligible. From the authors results it seems possible to conclude that, at least as far as the propagation is concerned, the 78 GHz band appears to be particularly suitable for spaceborn radar altimeter applications. (16 refs.)

110529 Seasonal distributions of diabatic heating during the First GARP Global Experiment. M.-Y.Wei (Space Sci. & Engng. Center, Univ. of Wisconsin, Madison, WI, USA), D.R.Johnson, R.D.Townsend.

Tellus Ser. A (Sweden), vol.35a, no.4, p.241-55 (Aug. 1983).

The seasonal and annual global distributions of diabatic heating during the First GARP Global Experiment (FGGE) are estimated using the isentropic mass continuity equation. The data used are from the FGGE Level IIIa analyses generated by the United States National Meteorological Center. Spatially and temporally coherent diabatic heating distributions are obtained from the isentropic planetary scale mass circulation that is forced by large-scale heat sources and sinks. (32 refs.)

110530 Effects of orography on Mediterranean lee cyclogenesis and its relationship to European blocking. S.Tibaldi (European Centre for Medium Range Weather Forecasts, Reading, England), A.Buzzi.
Tellus Ser. A (Sweden), vol.35a, no.4, p.269-86 (Aug. 1983).
The role of orographically-induced cyclogenesis in the lee of the Alps in favouring the onset of Euro-Atlantic blocking is investigated by means of numerical simulations of a real case. The model used is the ECMWF global grid-point model as operational in August 1980. While the essential part that the local orography (the Alps) plays in triggering the development of cyclonic disturbances is confirmed for the first time using a global model, the relationship between Alpine cyclogenesis and European blocking remains less clear. The importance of global orography in generating and maintaining the blocking pattern is subsequently investigated and its crucial role evidenced and discussed. (34 refs.)

110531 African wave disturbances in a general circulation model. M.A.Estoque, J.Shukla, J.G.Jiing (Rosentiel School of Marine & Atmospheric Sci., Univ. of Miami, Miami, FL, USA).
Tellus Ser. A (Sweden), vol.35a, no.4, p.287-95 (Aug. 1983).
Evidence is presented to show that African wave disturbances are reproduced in a general circulation simulation. The model used is the general circulation model developed by the Goddard Laboratory for Atmospheric Sciences of the National Aeronautics and Space Agency. The model is integrated in order to simulate the summer of 1974. A synoptic analysis of the simulated data over Africa for the month of July is performed. The results of the analysis show that wave disturbances are generated by the model; the behavior and the structure of the simulated disturbances are similar to those observed over tropical Africa during the northern summer. (15 refs.)

110532 Patterns of India monsoon rainfall anomalies. S.Hastenrath, A.Rosen (Dept. of Meteorology, Univ. of Wisconsin, Madison, WI, USA).
Tellus Ser. A (Sweden), vol.35a, no.4, p.324-31 (Aug. 1983).
Pattern characteristics of annual rainfall anomalies over India during 1900-72 are studied from precipitation records of 31 regional subdivisions and series of annual cyclone frequency and number of break monsoon days. Methods include spatial correlation, pattern stratification, and principal component and spectral analyses. (26 refs.)

110533 Elemental carbon in the atmosphere: cycle and lifetime. J.A.Ogren, R.J.Charlson (Dept. of Civil Engng., Univ. of Washington, Seattle, WA, USA).
Tellus Ser. B (Sweden), vol.35B, no.4, p.241-54 (Sept. 1983).
Particulate elemental carbon is found in the atmosphere in both urban and remote regions and is often responsible for much of the absorption of solar radiation by atmospheric aerosols. Its atmospheric lifetime is controlled by four factors: the initial size distribution, the concentration of ambient particles, the frequency and duration of precipitation, and the efficiencies of removal mechanisms. A model of the atmospheric cycle of particulate elemental carbon which includes these factors is used to estimate the range of atmospheric lifetimes expected under various conditions. (32 refs.)

110534 SO_2 and $SO_4^=$ in the arctic: interpretation of observations at three Norwegian arctic-subarctic stations. J.Heintzenberg (Dept. of Meteorology, Univ. of Stockholm, Stockholm, Sweden), S.Larssen.
Tellus Ser. B (Sweden), vol.35B, no.4, p.255-65 (Sept. 1983).
Three years of SO_2 and $SO_4^=$ measurements (1978-81) at three Norwegian arctic-subarctic stations (70, 74, and 79°N) are related to air mass trajectories. The average decrease in non-marine $SO_4^=$-concentrations with increasing latitude is found to agree well with the latitude distribution of direct- or short-path return-flow frequency of trajectories from the Eurasian source area. As expected from its reactive, short-lived character, average SO_2-concentrations decrease much more rapidly than the frequency of source trajectories when moving into the Arctic. The seasonal variations in sulphur concentrations and source trajectories are less well correlated, best at the southernmost station. From the study of all individual pollution episodes (defined by ≥ 2 times average sulphur concentrations) the authors deduce that an increasing fraction of high sulphur levels can be explained by long-path return flow, when moving deeper into the Arctic. (17 refs.)

110535 Atmospheric chloroform ($CHCl_3$): ocean-air exchange and global mass balance. M.A.K.Khalil, R.A.Rasmussen, S.D.Hoyt (Dept. of Environmental Sci., Oregon Graduate Center, Beaverton, OR, USA).
Tellus Ser. B (Sweden), vol.35B, no.4, p.266-74 (Sept. 1983).
Based on the observed global concentrations of chloroform ($CHCl_3$) in the air and seawater the authors demonstrate that the tropical oceans are a source of chloroform to the atmosphere. Even though the total yearly emissions of $CHCl_3$ from the oceans are still uncertain, the authors estimate the flux to be 0.35 Tg yr^{-1}. Anthropogenic sources are estimated. This result suggests that atmospheric $CHCl_3$ may be mostly natural in origin and not entirely man-made as previously thought. The global burden of $CHCl_3$ in the atmosphere is estimated. Removal mechanisms are suggested. (28 refs.)

110536 Parameterization of ice nucleation on insoluble particles. M.J.Manton (Div. of Cloud Phys., CSIRO, Epping, NSW, Australia).
Tellus Ser. B (Sweden), vol.35B, no.4, p.275-83 (Sept. 1983).
Ice nucleation on an insoluble particle is controlled by one of three limiting processes: sublimation, condensation and freezing (contact and immersion). The limiting process is determined by the supersaturation S and supercooling ΔT of the environment, and so nucleation occurs in three distinct regions of $(\Delta T, S)$ space. Within each region, the nucleation of large particles takes place at specified threshold values of ΔT and S. The threshold conditions depend upon three surface parameters, which are related to the contact angle between the nucleus substrate and the phases of water. As ΔT and S are raised above the threshold conditions, small particles are gradually nucleated. Thus the heterogeneous nucleation of ice can be specified in terms of the environmental conditions, ΔT and S, and the surface properties of the nuclei. (13 refs.)

110537 Predicting daily insolation with hourly cloud height and coverage. T.P.Meyers, R.F.Dale (Dept. of Agronomy, Purdue Univ., West Lafayette, IN, USA).
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.537-45 (April 1983).
